This section provides a general account of the long period of man's cultural-historical development during the Pleistocene ice age and the early Holocene or Recent epoch. During this approximately 500,000 years of prehistoric human development the climates and environments of the world fluctuated considerably, and there were, of course, no national boundaries or ethnological re-

gions that conformed in any meaningful way to those of the present. It would be impossible to maintain, on the basis of the archaeological evidence, that the inhabitants of what is now France were already Frenchmen 25,000 years ago or that the inhabitants of what is now Rhodesia were already Bantu-speaking Negroes 250,000 years ago. Hence the approach of this section is one of an overview of vast regions and of the great, general steps forward that human culture made from earliest times until the civilizations of the conventional ancient historians were well established. The rest of the article takes up the story in late pre- and protohistoric times, region by region, as the archaeological evidence begins to provide glimpses of a world that is presently to become as it is now known.

A. Culture History of the Pleistocene

Paleolithic archaeology is concerned with the origins and development of early human culture between the first appearance of man as a tool-using mammal, which is believed to have occurred about 600,000 or 700,000 years ago, and the beginning of the Recent geologic era, about 8000 B.C. It is included in the time span of the Pleistocene, or glacial, epoch—an interval of about 1,000,000 years. Although it cannot be proved, modern evidence suggests that the earliest protohuman forms had diverged from the ancestral primate stock by the beginning of the Pleistocene. In any case, the oldest recognizable tools are found in horizons of Lower Pleistocene Age. During the Pleistocene a series of momentous climatic events occurred. The northern latitudes and mountainous areas were subjected on four successive occasions to the advances and retreats of ice sheets (known as Günz, Mindel, Riss and Würm in the Alps), river valleys and terraces were formed, the present coast lines were established, and great changes were induced in the fauna and flora of the globe. In large measure, the development of culture during Paleolithic times seems to have been profoundly influenced by the environmental factors that characterize the successive stages of the Pleistocene epoch.

Throughout the Paleolithic, man was a food gatherer, depending for his subsistence on hunting wild animals and birds, fishing and collecting wild fruits, nuts and berries. The artifactual record of this exceedingly long interval is very incomplete; it can be studied from such imperishable objects of now-extinct cultures as were made of flint, stone, bone and antler. These alone have withstood the ravages of time and, together with the remains of contemporary animals hunted by our prehistoric forerunners, they are all that scholars have to guide them in attempting to reconstruct human activity throughout this vast interval—approximately 98% of the time span since the appearance of the first true hominid stock. In general, these materials develop gradually from single, all-purpose tools to an assemblage of varied and highly specialized types of artifacts, each designed to serve in connection with a specific function. Indeed, it is a process of increasingly more complex technologies, each founded on a specific tradition, that characterizes the cultural development of Paleolithic times. In other words, the trend was from simple to complex, from a stage of nonspecialization to stages of relatively high degrees of specialization, just as has been the case during historic times.

In the manufacture of stone implements, four fundamental traditions were developed by our Paleolithic ancestors: (1) pebble-tool traditions; (2) bifacial-tool or hand-ax traditions; (3) flake-tool traditions; and (4) blade-tool traditions. Only rarely are any of these found in "pure" form, and this fact has led to mistaken notions in many instances concerning the significance of various assemblages. Indeed, though a certain tradition might be superseded in a given region by a more advanced method of producing tools, the older technique persisted as long as it was needed for a given purpose. In general, however, there is an over-all trend in the order as given above, starting with simple pebble tools that have a single edge sharpened for cutting or chopping. But no true pebble-tool horizons had yet, by the second half of the 20th century, been recognized in Europe. In southern and eastern Asia, on the other hand, pebble tools of primitive type continued in use throughout Paleolithic times.

French place names have long been used to designate the various Paleolithic subdivisions, since many of the earliest discoveries were made in France. This terminology has been widely applied in other countries, notwithstanding the very great regional differences that do in fact exist. But the French sequence still serves as the foundation of Paleolithic studies in other parts of the old world, and it will be adhered to here.

Europe.—Three major subdivisions—Lower, Middle and Upper Paleolithic—are recognized in Europe. Although the dividing line between the lower and middle stages is not so clearly defined as that separating the middle and upper subdivisions, this system is still used by most workers.

Lower Paleolithic.—On the basis of the very rich materials from the Somme valley in the north of France and the Thames valley in the south of England, two main Lower Paleolithic traditions have been recognized in western Europe. These are as follows: (1) bifacial-tool or hand-ax traditions (Abbevillian and Acheulian); and (2) flake-tool traditions (Clactonian and Levalloisian).

The type tools of the Abbevillian (formerly Chellean), which takes its name from the town of Abbeville, France, on the 45-m. terrace of the Somme valley, consist of pointed, bifacial implements or hand axes. Their forms vary and the flaking is generally irregular; it is probable that they were manufactured either with a stone hammer or on a stone anvil. Associated with these crude types of hand axes, simple flake tools are found, but they lack definite form. The Abbevillian has been reported from deposits of Lower Pleistocene (first interglacial) Age.

The Acheulian, which begins in the second interglacial and persists to the close of the third interglacial, covers by far the longest time span of any of the Paleolithic traditions found in western Europe. The type site is on the 30-m. terrace of the Somme valley at St. Acheul, near Amiens, in northern France. Acheulian hand axes, which display a marked technological refinement over their Abbevillian precursors, were apparently made by employing a wooden or bone billet rather than the more primitive stone-on-stone technique. But, except at the very end of the Acheulian cycle of development, there is very little typological difference in the types of hand axes found in the various layers.

The Micoquian, or Final (Upper) Acheulian, is characterized by elongated hand axes that exhibit very straight and finely chipped edges, in marked contrast with the Lower Acheulian, in which ovate forms predominate. Flake tools occur in all Acheulian levels, the side scrapers being the predominant type. Many of these tools were made from trimming flakes produced during the process of hand-ax manufacture. In general, flake tools, including points with a triangular cross section, are found in greater quantities in Micoquian deposits than in the older horizons.

The evidence from Clacton-on-Sea, Essex, and Swanscombe, Kent, in the Thames valley of southeastern England clearly shows that the main development of the Clactonian occurred during early second interglacial times. The type artifacts are flakes, although core tools—single-edged choppers and chopping tools—do in fact occur. The flakes, which have large, high angle (greater than 90°), plain striking platforms and prominent bulbs of percussion, were detached from roughly prepared, discoidal cores by the stone-hammer or stone-anvil technique. Actual retouching or secondary working of the edge is found in some instances, but for the most part it is crude, and edge chipping resulting from use is far more characteristic.

Named after a locality at Levallois, a suburb of Paris, the Levalloisian is primarily a flake tradition, although hand axes are found in certain of the Middle and Upper Levalloisian stages. It first appears in deposits of the late second interglacial in association with hand axes of Middle Acheulian type, and persists into fourth-glacial (Würm) times. It is characterized by a new and improved method of producing flakes, which previously had been obtained in a more or less haphazard manner. This involves the careful shaping of the core by the removal of centrally directed flakes, and the preparation of an extremity for the detachment of a symmetrical oval flake. Since unstruck cores of this type exhibit a plano-convex section suggesting the form of a tortoise,

they are known as tortoise cores. On the striking platforms of typical Levallois flakes, small vertical flake scars, called facets, may be observed, and the scars of the converging core preparation flakes are present on the upper surface. The use of this technique resulted in the production not only of symmetrical flakes but also of larger ones in proportion to the size of the core. In the Middle and Upper Levalloisian a variation of this same basic technique was developed whereby it was possible to produce either triangular flakes (or points) or rectangular flakes (or flake blades) by modifying the method of core preparation.

Middle Paleolithic.—The Middle Paleolithic comprises the Mousterian, a portion of the Levalloisian and the Tayacian, all of which are complexes based on the production of flakes, although survivals of the old hand-ax tradition are manifest in many instances. These Middle Paleolithic assemblages first appear in deposits of the third interglacial and persist during the first major oscillation of the fourth-glacial (Würm) stage. Associated with the Tayacian, in which the artifacts consist of very crude flakes, remains of modern man (*Homo sapiens*) have been found. Mousterian man, on the other hand, is of the Neanderthal race. By the 1960s no human remains had yet been found associated with the Levalloisian. It is in the Mousterian levels of the caves and rock shelters of central and southern France that the earliest evidence of the use of fire and the first definite burials have been discovered in western Europe. The cave of Le Moustier, near Les Eyzies in the classic Dordogne region of France, is the type site of the Mousterian. The typology of the artifacts is complex; it consists of three distinct increments: (1) the prepared striking platform-tortoise core (Levalloisian) tradition; (2) the plain striking platform-discoidal core technique of ultimate Clactonian tradition; and (3) a persistence of the bifacial core tool or Acheulian tradition. The type artifacts from the Mousterian consist of points and side scrapers, in addition to a few hand axes (especially heart- or triangular-shaped forms), and the secondary working is coarse. A crude bone industry appears here for the first time. Judging by what is known concerning modern hunting groups, small bands or tribes of people already had developed simple social institutions, even at this early level of development.

Upper Paleolithic.—The Upper Paleolithic, which occupies only approximately one-tenth of the time span of the period as a whole, first appears in horizons referable to the Würm I–II interstadial, and it persists to the very end of late glacial times. Early man made his greatest cultural progress at this time. The hand axes and flake tools of the earlier assemblages were replaced by diversified and specialized tools made on blades struck from specially prepared cores. Many important inventions appeared, such as needles and thread, skin clothing, hafted stone and bone tools, the harpoon, the spear thrower and special fishing equipment. Bone, ivory and antler, in addition to flint, were extensively used. The earliest man-made dwellings are found, consisting of semisubterranean pit houses. Of prime importance and interest is the beginning of the basic techniques of drawing, modeling, sculpture and painting, as well as the earliest manifestations of dancing, music, the use of masks, ceremonies and the organization of society into patterns that were apparently fairly complex. Indeed, the location of certain settlements suggests a more complex social life, including perhaps collective hunting. There is evidence for fertility magic, private property and possible social stratification. Furthermore, primitive types of early man disappeared, and the remains of men of modern type (*Homo sapiens*) alone are found in Upper Paleolithic sites.

The chronology of this interval in western Europe shows a succession of cultures known as Lower Périgordian (or Châtelperronian; formerly Lower Aurignacian), Aurignacian, Upper Périgordian (or Gravettian; formerly Upper Aurignacian), Solutrean and Magdalenian, each characterized by its distinctive types of artifacts. These latter occur, together with gravers (or burins), end scrapers, points, etc., which are common to all levels. The graver itself is a very important tool, for its invention made possible the extensive working of bone and facilitated the development of art. The climate of the Upper Paleolithic varied from cold steppe, or even arctic tundra, to north temperate (taiga), similar to parts of Siberia and Canada of the present day.

In the Périgordian, named after a region in south-central France, blades with steeply retouched backs are typical. The Lower Périgordian is characterized by large curved points with blunted backs that are known as Châtelperron points. These first appear, together with other types of blade tools, in horizons immediately overlying Upper Mousterian levels. It is believed that the straight points with blunted backs, called Gravette points and characteristic of the Upper Périgordian, were evolved from the Châtelperron type. In the final stage of the Upper Périgordian, tanged Font Robert points and diminutive multiangle gravers, known as the Noailles burin, are found. A number of small sculptured human torsos depicting the female form have been found at Upper Périgordian sites.

The type site of the Aurignacian is near the village of Aurignac (Haute-Garonne) in southern France. At many sites it is found intervening between horizons referable to the Lower and the Upper Périgordian, a fact that is considered to indicate that more than one cultural element was present in western Europe at the beginning of Upper Paleolithic times. The tool types include various kinds of steep-ended scrapers, nose scrapers, blades with heavy marginal retouch, strangulated blades, busked gravers or burins and split-base bone points. Bone was extensively used, mainly for javelin points, chisels, perforators and *bâtons de commandement* or arrow straighteners. Articles of personal adornment, probably worn as necklaces, such as pierced teeth and shells as well as decorated bits of bone and ivory, appear for the first time in the Aurignacian.

The oldest manifestations of art were produced during the Aurignacian, and the development continued during Upper Périgordian times. In general, Upper Paleolithic art falls into two closely related categories: mural art and portable art. The former includes finger tracings, paintings, engravings, bas-reliefs and sculptures on the walls of caves and rock shelters; the latter is characterized by small engravings and sculptures on stone and bone found in the occupation layers. The whole development almost certainly owes its inspiration to the magico-religious idea, especially the custom of hunting magic as practised today by living primitive peoples.

The Solutrean, which is named after the site of Solutré, near Mâcon (Saône-et-Loire), is noted for the beautifully made, symmetrical, bifacially flaked, laurel-leaf and shouldered points, the finest examples of flint workmanship of the Paleolithic in western Europe. In addition, the usual types of gravers, end scrapers, points, perforators, etc., are present. Examples of Solutrean art are comparatively rare; they consist of sculpture in low relief and incised stone slabs. The fauna indicates that this culture flourished under conditions of a relatively cold climate.

The rock shelter of La Madeleine, near Les Eyzies (Dordogne), is the type Magdalenian locality. This final culture of the Upper Paleolithic is noted for the dominance of bone and antler tools over those of flint and stone, and for the very remarkable works of art that were produced at this time. The wide variety of bone tools include javelin points, barbed bone points (or harpoons), eyed needles, *bâtons de commandement* (often elaborately decorated), perforators, spear throwers, chisels, etc. The flint and stone tools include a variety of special forms, among which small geometric forms, denticulated blades, scrapers with steeply retouched edges and the parrot-beak graver are especially distinctive. The six phases of the Magdalenian have been established stratigraphically and are characterized mainly by the contained bone and antler implements. But the heights attained by the people responsible for this culture can best be evaluated on the basis of the art objects they produced. Magdalenian sites have yielded countless fine examples of both mural and portable art. Animals of the period, the usual subject matter, are portrayed in paintings (often polychrome), engravings and sculptures. The fauna from the various Magdalenian horizons demonstrates that cold conditions prevailed in western Europe at the end of Paleolithic times.

Africa.—The Paleolithic of Africa is characterized by a variety of stone-tool assemblages, some of which represent purely local

developments while others are practically identical with materials from corresponding horizons in Europe. Geological investigations of the Late Cenozoic deposits of this continent indicate that, as the result of fluctuations in rainfall, the Pleistocene epoch throughout most of Africa can be subdivided on the basis of a succession of pluvial and interpluvial stages. The pluvials, known as Kageran, Kamasian, Kanjeran and Gamblian, are believed to represent the tropical and subtropical equivalents of the four major glacial stages of the northern hemisphere, but this has not yet been proved. The archaeological succession is well established in certain areas, although not in the continent as a whole.

North Africa.—In this area, very crudely worked pebble tools have been reported from one site in Algeria in direct association with a Lower Pleistocene (Villafranchian) mammalian assemblage. Throughout Tunisia, Algeria, Morocco and the Sahara region, Lower Paleolithic hand axes of both Abbevillian and Acheulian type, together with flake tools, have been found in great numbers. The geological evidence shows that the Sahara region was far less arid during Pleistocene times than it is at present. The Middle Paleolithic of both Levalloisian and Mousterian facies is very widespread in north Africa, and it apparently persisted as late as the second maximum of the Würm glaciation in terms of the European sequence. A specialized Middle Paleolithic development, known as the Aterian, occurred there; it is characterized by tanged points made on flakes and flake blades. This was succeeded by two distinctive blade-tool complexes—the Capsian and Oranian—which are more or less contemporary. Their main development took place during the time span of the European Mesolithic. The Capsian sites are all inland, whereas the Oranian has a coastal distribution. Both are microlithic tool complexes which persisted after the introduction of Neolithic traits into the area.

Egypt.—The Pleistocene terrace gravels of the Nile valley in Egypt have produced a wealth of Paleolithic materials. The 30-m. terrace contains typical Abbevillian and early Acheulian hand axes, including a special form with a triangular section known as the Chalossian type. These are associated with primitive flake implements. In the 15-m. terrace, developed Acheulian has been recorded, while the 9-m. terrace yields large flakes and cores of Levalloisian type. In the low terrace, which occurs at a height of three metres above river level, developed Levalloisian (originally called Mousterian) has been reported. Overlying the low terrace, a local development known as the Sebilian is found. It contains very highly evolved flake implements of Levallois type and, in its later phases, a definite microlithic industry. Of approximately the same age as the Sebilian are several Epi-Levalloisian sites in the lower Nile drainage, including the Fayum depression and the Kharga oasis. In the latter area, where the specialized Levalloisian development is called the Khargan, an Egyptian version of the Aterian has been discovered.

East Africa.—In Kenya, Tanganyika and Uganda, very simple types of pebble tools, roughly chipped to an edge on one side only, occur in deposits of Lower Pleistocene Age. This development is known as the Kafuan, and it apparently evolved into an industry characterized by implements made on pebbles chipped to an edge on both sides, called the Oldowan. Overlying the latter are beds containing true Lower Paleolithic hand axes of Abbevillian and Acheulian type, together with flake tools. Associated with the Middle and Late Acheulian are cleavers made on flakes, as well as evidence of the use of the prepared striking platform-tortoise core (Levallois) technique in the production of flakes. In the next younger horizon, two distinct toolmaking traditions are found: (1) the Kenya Stillbay, a Levalloisian derivative characterized by small- to medium-sized, bifacially flaked points or minute hand axes; and (2) the Kenya Fauresmith, which is basically of Acheulian inspiration and very similar to the true Fauresmith of southern Africa. Carefully shaped round stone balls, believed to have been used as bola weights in hunting, constitute part of the Fauresmith assemblage. In the post-Gamblian dry phase, microlithic tools appear for the first time in an assemblage known as the Magosian. This was followed by the introduction into the area of a true blade technique, called the Kenya Capsian, together with the art of pottery making. More or less contemporary with the localities where the earliest pottery is found in east Africa, a series of sites has been discovered yielding typical microlithic assemblages and referable to the Kenya Wilton, also found in South Africa and the Rhodesias.

South Africa.—The sequence in southern Africa is well established on the basis of the terrace stratigraphy of the Vaal valley. Just as in north and east Africa, the succession begins in the basal Pleistocene with the occurrence of simple pebble tools of Kafuan type. These develop into what is called the pre-Stellenbosch which is found in the oldest gravels of the Vaal and which includes artifacts made on pebbles that recall both the Kafuan and the Oldowan. The true Stellenbosch complex occurs in the next younger series of deposits; it is simply a south African version of the Abbevillian and Acheulian of other parts of Africa and Europe. Typical are hand axes, cleavers, flakes struck from Victoria West cores and (in its later phases) various sorts of flakes produced by the prepared striking platform-tortoise core technique. The Stellenbosch was followed by the Fauresmith, which is characterized by evolved hand axes and Levalloistype flakes. The Stellenbosch and Fauresmith together comprise what is called the South African Older Stone Age, a period roughly corresponding to the Lower and Middle Paleolithic stages of Europe. On the other hand, the South African Middle Stone Age belongs to the later part of the Upper Pleistocene. It is characterized by a series of more or less contemporary flake tool assemblages, each of which displays local features. These are known as Mossel Bay, Pietersburg, Howieson's Poort, Bambata Cave, Stillbay, etc.; Stillbay which occurs in Kenya and Uganda, is the only one of these found outside south Africa. The characteristic tools are made on flakes produced by a developed Levalloisian technique, including slender unifacial and bifacial lances or spear points for stabbing or throwing. In the final stages of the Middle Stone Age, known as the South African Magosian, microlithic elements appear, just as in the case of east Africa. The Later Stone Age cultures of this region—the Smithfield and the Wilton—developed during post-Pleistocene times. These are closely related and, in their later stages, reveal varying degrees of influence as the result of contact with the culture introduced by the Bantu-speaking peoples. Both were extant at the time the first Europeans arrived in south Africa, and there is little doubt that the Wilton, which is a typical microlithic assemblage, is to be associated with the modern Bushmen. There are many paintings in the rock shelters and engravings on stones in the open-air sites of south Africa, the oldest of which belong to the Later Stone Age. The naturalistic style of art revealed at these sites persisted until well into historic times.

Central Africa.—The Lower Paleolithic sequence of central or equatorial Africa is essentially a repetition of what has already been outlined for east and south Africa. At the beginning of Middle Stone Age times, however, a special development took place known as the Sangoan (formerly Tumbian). This is characterized by picks and adzes made on bifacially flaked cores, the tranchet type of ax, hand axes of developed Acheulian form, massive side scrapers and many elongated, bifacially flaked points that probably served as lances or spearheads. The Sangoan seems to represent a response to the environmental conditions of this tropical rain-forest region. Its main development took place during Upper Pleistocene times, but it persisted after the introduction of Neolithic traits into the area.

Asia.—During the Paleolithic, two major culture provinces can be recognized in Asia, each of which has yielded a distinctive sequence. The first of these includes the near east, Russian Turkistan, central Siberia and India; throughout this vast region a developmental sequence has been reported which, in all its essential respects, is related to that of Europe as well as to that of Africa in the early stages. The second of these provinces is in the south and east, and it embraces Pakistan, Burma, Java, Malaya, Thailand and China. There the characteristic implement types consist of choppers and chopping tools that are often made on pebbles. In Africa such pebble-tool assemblages as the Kafuan, Oldowan and pre-Stellenbosch are widely distributed, as stated above, and they first appear in beds laid down in Lower Pleis-

tocene times, but by the Middle Pleistocene they were replaced (or superseded) by hand-ax industries of Abbevilleo-Acheulian type. The latter are missing in southern and eastern Asia, together with the intimately associated prepared striking platform-tortoise core, or Levallois, technique. There the pebble-tool tradition persisted to the very end of Paleolithic times uninfluenced by contemporary innovations characteristic of the western portion of the continent.

Near East.—In this area, especially in Israel, Jordan, Lebanon and Syria, a Lower Paleolithic development closely paralleling that of Europe is indicated by the widespread distribution of hand axes of Abbevillian and Acheulian type. Unfortunately, the majority of these finds are from open-air, unstratified sites that cannot be dated. A crude flake industry, reminiscent of the Tayacian of western Europe, has been reported from several cave sites. This is followed by a typical Upper Acheulian horizon in which there occur many developed hand axes of Micoquian type, a wide variety of flake implements and the prepared striking platform-tortoise core technique. The Levalloiso-Mousterian found in the next younger horizon is associated with a series of Neanderthaloid burials at one of the Mt. Carmel caves of Israel and at Shanidar cave in northern Iraq. Next in the sequence comes an early Upper Paleolithic development, which is characterized by various types of blade and flake-blade tools, including points that recall the Châtelperron type. This is overlain by the Antelian (formerly Middle Aurignacian), which in turn is followed by the Atlitian and the Kebarian. These assemblages, together with the recently discovered Baradostian of northern Iraq, constitute specialized late Upper Paleolithic industries which preceded various Mesolithic developments in the middle east.

Central Asia.—In the central Asiatic parts of the U.S.S.R. (formerly Russian Turkistan), few investigations of Paleolithic sites have been conducted. Surface finds of Acheulian-type hand axes have been reported from the Turkmen republic, and several Mousterian localities have been excavated in the southeastern Uzbek republic. At the most important of these—the cave of Teshik-Tash—the burial of a Neanderthal child surrounded by horns of the Siberian mountain goat was discovered. Up to the early 1960s no convincing evidence had been reported showing that this region was occupied during Upper Paleolithic times.

India and Pakistan.—Certain of the Paleolithic assemblages from India and Pakistan demonstrate that during Pleistocene times the region played an intermediate role between western Asia and the far east. In the Punjab province of Pakistan, assemblages of implements characteristic of both the chopper-chopping tool and the hand ax-Levallois flake complexes are found. The former, called the Sohanian, or Sohan, has been reported from five successive horizons, each of which yields pebble tools associated with flake implements. Massive and crude in the earliest phases of the Sohanian, these reveal a progressive refinement in the younger horizons, where the evolved pebble tools are associated with flakes produced by the prepared striking platform-tortoise core technique. In part contemporary with the Early Sohanian is a series of hand axes of Abbevilleo-Acheulian affinities, which occur in profusion at many sites in India from the Gujarat region in the north to the Madras in the south. These sites yield hand axes, cleavers and flake tools that are very reminiscent of assemblages from south and east Africa. As in the latter areas, the oldest materials are of Abbevillian type, and this is followed by the entire Acheulian cycle of development, just as in the case of the Stellenbosch of the Vaal valley. The occurrence of choppers and chopping tools of Sohanian affinities and made on pebbles throughout peninsular India in deposits of Middle Pleistocene Age suggests the probability that Lower Pleistocene horizons will ultimately be found in this area containing only pebble tools, as in the case of Africa.

As of the early 1960s, no convincing evidence had been reported to indicate that a blade-burin complex was introduced into India before the close of Paleolithic times.

Far East.—Pebble tools, including choppers and chopping tools, are found in the Pleistocene terrace deposits of the Irrawaddy valley of upper Burma. This complex is known as the Anyathian. The Early Anyathian is characterized by single-edged core implements made on natural fragments of fossil wood and silicified tuff, and these are associated with crude flake implements. In the Late Anyathian, a direct development from the earlier stage, smaller and better-made core and flake artifacts are found. No hand axes or flakes produced by the prepared striking platform-tortoise core technique have been found in Burma.

Elsewhere in the far east, pebble tools have been reported from deposits apparently of Middle Pleistocene Age in western Thailand, for which the name Fingnoian has been proposed. In northern Malaya a large series of choppers and chopping tools made on quartzite pebbles and found in Middle Pleistocene tin-bearing gravels have been referred to collectively as the Tampanian, since they come from a place called Kota Tampan in Perak. Still another late Middle Pleistocene assemblage, called the Patjitanian, is known from a very prolific site in south-central Java. In both the Tampanian and Patjitanian the main types of implements consist of single-edged choppers and chopping tools that occur in association with primitive flakes with unprepared, high-angle striking platforms. Also in both assemblages is an interesting series of pointed, bifacial implements that have been described as crude hand axes. Since these tools are very rare in each instance and are absent in Burma, it is probable that they were developed in southeastern Asia independently of influences from the west. Several sites of Upper Pleistocene Age in central Java have produced artifacts made on small- to medium-sized flakes and flake blades. Antler and bone implements belong to this complex, known as the Ngandongian, which has also been reported from the Celebes and from the Philippines.

One of the oldest Lower Paleolithic occupation sites ever discovered is near the village of Chou-k'ou-tien, about 30 mi. S.W. of Peking in northern China. Associated with the remains of Peking man (*Sinanthropus pekinensis*), pebble tools, together with quartz flake implements, occur in quantity. This assemblage, known as the Choukoutienian, is of Middle Pleistocene Age; it forms an integral part of the chopper-chopping tool tradition of the far east.

Also in north China several Upper Paleolithic sites are known in the provinces of Shansi, Shensi and northern Kansu, in the region encompassed by the great bend of the Yellow river (Huang Ho). Collectively known as the Ordosian, these materials are of Upper Pleistocene Age. Typical of the Ordosian are blade implements of various types, points and scrapers of Mousterian-like appearance and pebble tools of Choukoutienian tradition. Originally classified as Moustero-Aurignacian, it later became apparent that this development had much in common with that of the Yenisei-Baikal region to the north in central Siberia.

The archaeological materials from the loess sites of Siberia between the Yenisei valley and the Lake Baikal area is an interesting mixture of (1) blade tools, together with antler, bone and ivory artifacts of classic Upper Paleolithic type; (2) points and scrapers made on flakes of Mousterian aspect; and (3) pebble tools representing a survival of the ancient chopper-chopping tool tradition of eastern Asia. Remains of semisubterranean dwellings with centrally located hearths occur at certain of these stations, together with female statuettes in bone. One of the most striking features of this Siberian Upper Paleolithic is the fact of its comparatively late survival: in terms of the European sequence, it seems to have persisted as late as Early Mesolithic times. Indeed, in several instances it actually occurs in the uppermost layer of loess immediately below a horizon of humus containing Neolithic camp sites. The problems of the Siberian Upper Paleolithic are of obvious importance to students of new-world archaeology, since they have an intimate and direct bearing on the question of the peopling of the Americas.

B. The Old World of the Recent Period

There is reasonable agreement that the Paleolithic ended with the beginning of the Recent (Holocene) geologic and climatic era about 8000 B.C. It is also increasingly clear that a developmental bifurcation in man's culture history took place at about this time. In most of the world, especially in the temperate or tropical woodland environments or along the southern fringes of arctic tundra, the older Upper Paleolithic traditions of life were simply readapted toward more-or-less increasingly intensified levels of food collection. These cultural readaptations of older food procedures to the variety and succession of post-Pleistocene environments are generally referred to as the Mesolithic stage. But also by 8000 B.C. (if not even somewhat earlier) in certain semiarid environments of the world's middle latitudes, traces of a quite different course of development began to appear. These traces indicate a movement toward incipient agriculture and (in one or two instances) animal domestication. In the case of southwestern Asia, this movement had already culminated in a level of effective village-farming communities by 7000 B.C. In Mesoamerica, a comparable development—somewhat different in its details and without animal domestication—was taking place almost as early. It may thus be maintained that in the environmentally favourable portions of southwestern Asia, Mesoamerica, the coastal slopes below the Andes, and perhaps in southeastern Asia (for which little evidence is available), little if any trace of the Mesolithic stage need be anticipated. The general level of culture probably shifted directly from that of the Upper Paleolithic to that of incipient cultivation and domestication.

The picture presented by the culture history of the earlier portion of the Recent period is thus one of two generalized developmental patterns: (1) the cultural readaptations to post-Pleistocene environments on a more-or-less intensified level of food collection; and (2) the appearance and development of an effective level of food production. It is generally agreed that this latter appearance and development was achieved quite independently in various localities in both the old and new worlds. As the procedures and the plant or animal domesticates of this new food-producing level gained effectiveness and flexibility to adapt to new environments, the new level expanded at the expense of the older, more conservative one. Finally, it is only within the matrix of a level of food production that any of the world's civilizations have been achieved (see *Civilizations*, below).

The Level of Intensified Food Collecting.—In the Upper Paleolithic of Europe, certain evidence exists for what must have already been well-organized collective-hunting activities, such as the horse-stampede traces at Solutré, France, and the great concentrations of mammoth bones of the Gravettian hut settlements of Czechoslovakia and Russia. Cultural adaptations appear to have been made to restricted local areas or niches and to the fluctuations of climate and environment during the changing phases at the end of the Pleistocene range of time. In fact, it could be maintained generally that Upper Paleolithic traditions flowed rather smoothly into the Mesolithic, with no more significant indication of cultural development than further environmental readaptations. The people of the Mesolithic stage or level of development "changed just enough so that they would not have to change."

The Maglemosian.—The level of intensified food-collecting cultures of the early Recent period in the old world is best known from northwestern Europe, and it is with regard to this area that the term Mesolithic has greatest currency to denominate archaeological traces. A classic example of such traces comes from the Maglemose bog site of Denmark, although there are comparable materials ranging from England to the eastern Baltic lands. These bogs were probably more-or-less swampy lakes. At about 6000 B.C., when the Maglemosian culture flourished, traces of primitive huts with bark-covered floors have been found. Flint axes for felling trees and adzes for working wood have appeared, as well as a variety of smaller flint tools, including many of microlithic scale. These were mounted as points or barbs in arrows and harpoons and were also used in other composite tools. There were adzes and chisels of antler or bone, besides needles and pins, fish hooks, harpoons and several-pronged fish spears. Some larger tools, of ground stone; *e.g.*, club heads, have appeared. Wooden implements also have survived because of the unusually favourable preservative qualities of the bogs; bows, arrow shafts, ax handles, paddles and even a dugout canoe have been discovered. Fish nets were made of bark fibre. There is good evidence that the Maglemosian sites were only seasonally occupied. Deer were successfully hunted and fish and waterfowl were taken, and it appears possible that several varieties of marsh plants were utilized. At Star Carr, in northern England, there are indications that four or five huts existed in the settlement, with a population of about 25 people.

This description of the Maglemosian must suffice to represent a considerable variety of European manifestations of the level of intensified post-Pleistocene food collecting. The catalogues of the Azilian and Tardenoisian industries of western Europe, of the Ahrensburgian of north Germany, of the Asturian of Spain, etc., would each differ in detail, but all would point in the same general

direction as regards cultural-historical interpretation.

The Nachikufan.—As a further and far-distant example, the Nachikufan culture of southern Rhodesia might be cited. Here again, microlithic flint bladelet tools, with certain types mounted as projectile points or in composite tools, existed. The Nachikufan cave walls show a few seminaturalistic drawings, and the caves also contain "pencils" of red and black pigment. Ground stone axes and adzes, bored stones (digging-stick weights?) and normal-sized chopping and scraping tools of chipped stone also occurred. Grindstones of various types indicate a degree of dependence on collected vegetable foods, and the animal bones suggest specialization in the hunting of zebras, wildebeeste, hartebeeste and wild pig. These Nachikufan materials date back to at least 4500 B.C. Again, an intensified level of food collecting is implied.

The General Picture.—Though there are vast gaps in our knowledge of the Recent period in many parts of the old world, enough is known to see the general cultural level of this range of time. Outside of the regions where food production was establishing itself, the period was one of a gradual settling-in and of an increasingly intensive utilization of all the resources of restricted regional niches. At first, the level seems nowhere to have achieved a climax of artistic expression, such as that for example, of upper Périgordian-Magdalenian times. But, as time went on, certain climaxes within the matrix of an intensified level of food collection did occur. An often-cited example might be the complex art and social organization of the cultures of the northwest coast of British Columbia.

More often, however, as the culture history of the Recent period proceeded, cultures at the level of intensified food collecting were "captured" by being absorbed within an expanding matrix of the new elements, procedures and traditions of food production or—subsequent to its appearance—by the expansion of civilized societies.

The Rise of Village-Farming Communities in the Near East.—There is little question that a level of an effective food-producing, village-farming-community way of life had been achieved in certain portions of southwestern Asia by at least 7000 B.C. Furthermore, increasing evidence indicated that the effective village-farming level was preceded by one of cultivation and animal domestication and that this incipient level was at least under way by about 9000 B.C.

Incipient Cultivation and Domestication.—Recent research suggests that the level of incipient cultivation and domestication was essentially restricted to the piedmont and intermontane valley zone which flanks the Zagros-Taurus-Lebanon chain of highlands about the great basin of the upper Tigris-Euphrates and Karkheh-Karun rivers and their tributaries. There are even hints that the zone extended to parts of the Iranian and Anatolian plateaus and that it may possibly have fingered northwest toward European Thrace. The significant point is that the zone appears to have formed a natural habitat for the cluster of plants and animals which were potentially domesticable. These subsequent domesticates—wheat, barley, sheep, goat, cattle and pig, plus a possible wolf dog—still exist in their wild state in those parts of the zone which have been examined by prehistoric archaeologists and natural scientists. An exact definition of the boundaries of this zone during the period from 10000 to 8000 B.C. was not available, however, in the 1960s.

The level of incipient cultivation and domestication is best manifested by the archaeological materials of the Natufian group in the Palestine-Syro-Lebanese littoral and parts of its hinterland, and by the Karim Shahir group in Iraqi and Iranian Kurdistan. The possibility of a continuation of the level into the northern Syrian and southern Turkish portions of the natural-habitat zone has been essentially untested by modern field research. Both of the available complexes of materials, the Natufian and the Karim Shahirian, appear to have been established by about 9000 B.C.

The Natufian and Karim Shahirian.—In both, there are clear indications of open settlements of modest size, with some traces of round huts, some of which were built on stone foundations, although caves are also known to have still been inhabited. Both groups yield traces of normal developments of flint industries based essentially upon local Upper Paleolithic antecedents, and both must have been influenced in their food getting by the already intensified food-collecting practices of their immediate predecessors. It is freely admitted that the postulation of this incipient level rests considerably on a judgment based on the materials of the succeeding level of effective village-farming communities. Nevertheless, it has been demonstrated that sheep were already being used at the incipient level, and there are such hints as flint sickles, ground stone mullers, mortars and pestles, and probable hoe blades to suggest that food plants were also receiving marked attention. Claims for the domesticated dog in the Natufian are not universally accepted, however. It has been rightly stressed that the materials of this level will be exceedingly difficult to interpret, since the earliest plant and animal domesticates will show little morphological difference from their wild contemporaries and since the procedures and artifacts of the new food-getting and food-preparation techniques will have taken considerable time to develop.

The Effective Village-Farming Community.—The next level, that of the effective village-farming community, yields, even in its earliest available phase (at Jarmo, in Iraqi Kurdistan, *c.* 7000 B.C.), materials which leave little doubt about the presence of food production. In the Jarmo phase, wheat, barley, a pea, goats, sheep, and—before the phase is completed—pigs and probably dogs all appear. The Jarmo settlement suggests a permanent village of about 20 rectangular several-roomed huts, which probably had a population of at least 150 people. Several other variants of the Jarmo phase have been excavated or at least located in Kurdistan. One of these, Sarab, near Kermanshah in Iran, suggests a seasonal encampment of herdsmen. Sarab yields pottery throughout its shallow deposit; at Jarmo itself, similar pottery appeared only in the upper third of a much thicker deposit.

"Preceramic" village sites were recovered in the 1950s in the Dead sea valley, along the Syro-Palestinian littoral, on Cyprus, in the southwestern Turkish highlands and even in Thessalian Greece. Controversy exists regarding the very spectacular architectural remains of the Dead sea valley site of Tall as Sultan (reputedly also the site of the later Jericho), with disagreement about its "town" or even "urban" nature in view of the normal small-object assemblage there, the radiocarbon determinations now available for it, and the relative lack of firm evidence for cultivation. These disagreements will certainly be resolved as more sites in the time range of about 9000 to 6000 B.C. are excavated in the Syro-Palestinian littoral and in parts of its hinterland. Further understanding should result as excavations proceed at Ras Shamra (north Syria) and at Hacilar and Catalhuyuk in southwestern Turkey.

Fully Established Village Sequences in the Near East.—By, or soon after, 6000 B.C., a variety of more-or-less complete regional cultural sequences developed in the near east. In Iran, two sequences appeared. That beginning at the site of Sialk developed most characteristically in the northern and northeastern parts of the country and evidently extended into the Turkmen Soviet Socialist Republic and northern Baluchistan and perhaps beyond to the Indus. A somewhat different tradition developed in southwestern and southern Iran, early traces of which may be seen at Ja'farabad in Susiana (Elam) and at Bakun B near Persepolis. This tradition exhibited a closer proximity to the earlier sites in Iraq; its eastern extension may also be traced as far as Baluchistan, if not beyond into the Indus valley.

The earliest full-bodied assemblage in northern Iraq, following that of Jarmo, is the Hassunan of the Mosul-Kirkuk piedmont. Next—either as elements in the developed Hassunan phases or alone at the mid-Euphrates site of Baghouz or at the mid-Tigris site of Samarra—comes the Samarran phase. Then, with further overlap, comes the Halafian phase of the upper (Syro-Turkish-Iraqi) piedmont. The overlapping of these three assemblages is indicated by the availability of a radiocarbon determination for an early Halafian level, which is as early as either of the two determinations of the Hassunan—about 5750 B.C. The beginning of the food-producing sequence in classic southern Mesopotamia comes after this time and is, perhaps, partly an amalgam of (1) a south-

ward extension of Hassuna-Samarra-Halaf traits; (2) the westward extension of early Susiana traits from southwestern Iran; and (3) the probable presence of indigenous riverine-oriented food collectors.

Another local tradition, at least contemporary with that of Hassuna (and perhaps earlier than that of Sialk), appears to have its focus in the Syro-Cilician corner of the eastern Mediterranean; its preceramic antecedents may be seen in the basal levels of coastal Ras Shamra. Later, this Syro-Cilician tradition appears to have been affected by the Halafian and later inland developments. To the north of Syro-Cilicia the early materials of Hacilar and of Catalhuyuk must be given place, including the possibility of their implications for the early developments in the Aegean. To the south, the Syro-Cilician tradition merged gradually into a somewhat related coastal Palestinian tradition. But in the more arid reaches of inland Palestine, a somewhat different tradition developed that appears to have culminated in the sites of semi-nomadic traders such as that at Beersheba.

Food production appears to have reached Egypt (and northern Africa generally) relatively late, perhaps not much before 4500 B.C. Such northern Egyptian occurrences as Merimde (on the western flank of the Nile delta) and the Fayum A pit sites might argue for an expansion directly (by boats?) from the Asian coast. But some authorities favour the idea of a way into middle Egypt via the Red sea and the Wadi Rawd 'Aid to account for the available developments there.

General Cultural Level of the Early Villages.—This very compressed sketch is meant only to suggest the variety of regional variations and adjustments within the general development of the effective village-farming level in the near east, from about 6000 to 4500 B.C. Wheat and barley were the staple crops; cattle join sheep, goats and pigs as major food animals at least by the Halafian phase. Villages—except the Tall as Sultan fortified establishment—seldom have a proved area of more than four or five square meters; an informed guess would put their limit of population at about 500 people. Again, except for some dubious interpretations of certain rather modest buildings as "shrines," the architecture appears to be entirely domestic in nature. Aesthetic expression also took the form of an almost bewildering variety of regionalized and successive painted-pottery styles. The modeling of clay figurines—already well attested in the phase of Jarmo and its contemporaries—continues, with both animals and stylized human females being rendered. The latter, especially, may be suspected as having represented some magico-religious aspect of concern with fertility, upon which the livelihood of the communities depended. Flint tools were gradually replaced by copper and, eventually, by bronze implements, and the early trade routes in obsidian (a volcanic glass of restricted occurrence) were doubtless taken over by the metallurgists. Certain artifacts indicate the presence of weaving; in addition to their local utility, woven fabrics may also have served as media of exchange. It would be difficult to maintain that there was a strict subdivision of labour on a full-time scale (except perhaps on a basis of sex or age), but such a trend must have been setting in.

It should be emphasized that the complexity of this picture cannot readily be conceived apart from a system of effective food production. It may also be noted that an older trend was not being reversed. The intensified food collecting at the close of the Pleistocene was apparently accompanied by increasing regional specialization and a tendency toward full utilization of a rather restricted environmental niche. Now—with the establishment and spread of the effective village-farming community, its expansion beyond the confines of the natural-habitat zone, and the beginnings of trade—the horizon began to widen again. The *oikoumenē*, or known world of these first effective village farmers, became an ever expanding one. Hence, just as it is probably not very fruitful to ask exactly where any particular element was "invented" or first discovered within the level of incipient cultivation and domestication in the natural-habitat zone, it is probably most useful to view the development of the way of life of the effective village-farming community as a general regional phenomenon of cultural interrelationships and stimulations. It might be further suggested that this general development took place over a broad area which had certain localized environmental variables and natural resources. These environmental conditions, however, had been there, just as the natural-habitat zone itself had been, long before incipient and effective food production came into being. The latter were human, cultural achievements; favourable environment, though it enabled them to come into being, did not cause them.

The Threshold of Town and City Life in the Near East.—The end of prehistory and the threshold of urban civilization are first seen in classic southern Mesopotamia about 4500 B.C. The materials of the Ubaidian assemblage make their appearance after a still rather poorly delineated phase in the basal levels of the mound of Eridu. Whatever elements combined in the earliest amalgam (northern Iraqian, Susianan or indigenous), the resultant traits of the Ubaidian tradition are revealed in their greatest clarity, consistency and variety in southern Mesopotamia by 4000 B.C.

There are mound accumulations and at least one large cemetery which suggest a scale of communities well beyond that of the simple village. Buildings sufficiently large, formal in design and size, monumental in concept and decoration to be judged as temples were present. Great quantities of painted pottery of high quality appear in the excavations. This pottery, by its very uniformity and the somewhat cursive nature of its decoration, may already have been the product of specialized craftsmen. No unquestionable instances of metal tools were available by the early 1960s from Ubaidian contexts in southern Mesopotamia (although metal was available by that time in the north), but quantities of very highly fired clay tools (axes, adzes, sickles) had been found. These were useful for cutting the pithy woods, reeds and grain of the southern alluvial environment or for dressing sun-baked bricks. The female clay figurines continued, but in a unique and highly characteristic stylization.

General Cultural Level of the Ubaidian Phase.—A Ubaidian town supplied itself from fields of wheat and barley and its animal herds. However, the agricultural regime in the hot, dry alluvium of southern Mesopotamia depended upon the utilization of the braided lower channels of the Tigris and especially of the Euphrates. Though elaborate irrigation works did not exist, the management of even quite informal ditches, with necessary shifts when the natural channels of the rivers shifted, added a new dimension to the sociopolitical necessities of Ubaidian culture. This system of irrigation may have been one of the factors which contributed to the expansion of society in late prehistoric Mesopotamia. Given the proper management and water, the yield of the rich alluvial soil was magnificent (until salinity became a problem several centuries later). There were also important dietary additions, such as dates from the groves of date palms and fish from the river channels and ditches.

With southern Mesopotamia as its focus, the Ubaidian tradition "exported" some of its elements at least as far as the Mediterranean coast and throughout the great upper drainage basin of the Tigris-Euphrates and Kakheh-Karun rivers. These exported traits doubtless reflect the growth of another *oikoumenē*, and one much more explicitly southern Mesopotamian in character. In southern Mesopotamia itself, the Ubaidian phase was followed (after a "Warkan" interval) by the proto-Literate period, in which the usual criteria of civilization are manifest.

Other Possible Origins of Food Production.—Some authors maintain that at least one important, quite independent and perhaps even earlier centre of cultivation and domestication lay well to the east of the southwestern Asiatic one. Southeastern Asia—under the circumstances, exactly where cannot be made explicit—is often suggested. There are also one or two champions for sub-Saharan Africa. It is, indeed, quite possible (perhaps even probable) that a southeastern Asiatic focus of domestication for certain tropical plants,—*e.g.*, the taro, the breadfruit, the yam, the banana—did in fact exist. Again, an independent domestication of wild pig, water buffalo and other animals, along with the chicken, may also have occurred in the area. The history of these domesticates as well as that of rice and certain other Indian plants, is not at all clearly understood. In Africa, the case is made on the grounds

of reputedly early (5th millennium B.C.) domestications of certain species of millet, sorghum, a pea, several tubers and root crops, and the watermelon.

The difficulty in deciding about such origins is that nowhere in either southeastern or southern Asia, nor in sub-Saharan Africa, is there any direct archaeological evidence bearing on these possible achievements. But, based on a judgment of what ought to have happened because of the later developments actually known to have occurred in areas, it is not unreasonable to conclude that early cultivation and animal domestication very likely took place there. The issue of how completely independent these achievements may have been is a much more troublesome problem, for it can equally well be maintained that the southeast Asian and sub-Saharan developments depended on the borrowing of ideas, or stimulus diffusion, from southwestern Asia. Even if this were the case, however, an important element of independence would still be involved in the application of borrowed ideas to quite different environmental scenes with their different potential domesticates, and the development of procedures and tools to assure effective food production on the basis of these new possibilities. The resultant complexion of the cultures which utilized these regional domesticates through tools and procedures they themselves had produced need hardly be thought of as simply pale reflections of the focus from which the original (and doubtless very generalized) idea was borrowed.

East of Southwestern Asia.—It is known, however, that village-farming communities existed in the Indus valley as early as 3000 B.C., if not earlier. The original complexion of their assemblages resembled those of Iran (and perhaps those of the Ubaidian imprint on southwestern Iran), but this complexion gradually changed to something characteristic of the Indus valley itself and evidently culminated in the Harappan urban civilization. Some degree of contact between the cities of the Indus and of Mesopotamia certainly continued to exist, however. It is becoming evident that the Harappan complex was not restricted to the Indus valley alluvium but extended into the adjacent semitropical portions of India as well.

Knowledge of the developmental sequence in China is obviously incomplete. Except for a few snatches of typologically more simple materials, the first evidence of food production in China appears to pertain to a well-advanced phase of the effective village-farming-community level. This is the Yangshao complex, focused in the basin about the confluence of the Yellow river (Huang Ho), Fen Ho and Kuei Shui rivers. Characterized by a handsome painted-pottery style, the Yangshao catalogue also includes cultivated millet, rice, kaoling and possibly soybeans, as well as domesticated pig, cattle, sheep, dog, chicken and possibly the horse and silkworm. The village houses were built of tamped earth; there was a flourish of "ceremonial" pottery vessels and of elaborately worked objects in jade, as well as flint, bone and ground stone objects of daily use. The Yangshao phase is followed by that called Lungshan, after which comes the Yin or Shang early dynastic complex of about 1500 B.C. The date for the beginning of the Yangshao is unknown; 3500 B.C. is probably much too early. Our comprehension of China is approximately comparable to what our knowledge of Iraq would be if we knew nothing earlier there than the Halaf phase.

Even less is known of southern China and southeastern Asia; the former seems to have been affected by the expansion of the makers of the Lungshan black pottery and perhaps was also stimulated from the south. The rather amorphous Hoabinhian and Bacsonian sequence in Indochina, with ground stone axes and adzes, appears to be quite late—perhaps of the 1st millennium B.C. In Japan, on the other hand, the first appearance of pottery of early Jōmon type (evidently all of the Jōmon development lies before effective cultivation had begun) has several radiocarbon determinations at about 7000 B.C., but some authorities suspect contamination of the samples. Positive cultivation (wet rice) appears in Japan about 300 B.C., in the Yayoi phase.

Sub-Saharan Africa.—The case of sub-Saharan Africa is complicated by the fact that the elements and procedures of food production are known to have spread southward along the Nile and across the Sahara from northern Africa. The wheat-barley and sheep-goat complex is not native to Africa, but cattle could have been domesticated there if the native north African *Bos opisthonomous* was utilized. An interesting development in Kenya and northern Tanganyika is the so-called stone-bowl culture, which must extend back to 1000 B.C. and probably somewhat earlier. Here, sheep and cattle were kept, and it seems very probable that certain millets were cultivated. Less is known of the area west of the Kenya-Tanganyika highlands; lack of excavation, poor preservation conditions in the tropical-forest environment, and the unlikelihood that stock raising could have been practised there, are factors which contribute to our ignorance. It is certainly not impossible that local plants were used—probably as the result of the diffusion of ideas from the north or east—but this is not known to have occurred until quite late.

Diffusion From the Near East to Europe.—The appearance of an effective village-farming-community way of life in Europe depended upon a combination of direct and stimulus types of diffusion from southwestern Asia. The plant and animal domesticates which reached Europe were those of the southwestern Asiatic complex, but it is very important to visualize their adaptive adjustments to the new, more temperate environments of Europe, and the changes in the procedures and tools which were also necessary to make food production effective in the new environments. Moreover, the new pattern of life did not move into a vacuum but into an area already occupied by intensive food collectors. It is unlikely that many people or ideas were carried directly from southwestern Asia to Europe; it appears, rather, that the spread was relatively slow (about 3000 years from, *e.g.*, Syro-Cilicia to the Rhine delta), with necessary adjustments and adaptations along the way.

Hence, it has been rightly maintained that the peoples of Europe were not slavish imitators and that they took "the gifts of the East" and molded them into a new, organic whole capable of developing along its own lines. This was the final achievement of prehistoric Europe and the basis upon which its subsequent civilizations were to arise.

See R. J. Braidwood and G. R. Willey (eds.), *Courses Towards Urban Life: Archeological Considerations of Some Cultural Alternates*, Viking Fund Publications in Anthropology no. 31 (1962), which contains a detailed treatment of the subject matter of this article, together with a full bibliography. (R. J. B.)

C. The New World Prior to Urban Civilization

The prehistoric sequence in the new world shares many essential developmental features with the old world and provides a test for generalizations about cultural development based upon old-world materials. In the new world there is evidence for an early horizon of primitive food collectors, followed by an increasing specialization of food collecting based primarily upon differences in localized resources. These specialized collectors were followed by a tradition of food production independent of the old world.

With food production came gradual increases in centres of population; villages were succeeded by towns and finally by centres of urban civilizations, which at the time of European contact were comparable to the ancient civilizations of the near east.

The absence of a suitable fossil record and of cultural remains from Early and Middle Pleistocene deposits in the new world have led prehistorians to look to the old world as the ultimate source of the diverse populations of American Indians found in the western hemisphere by the early European explorers. Present knowledge of Pleistocene glaciations and of accompanying alterations in sea level indicates that the most probable route of entry for man from the old world was via a land bridge between Alaska and Siberia, crossing what is now the Bering strait. It appears that a dry-land crossing of this area was possible during periods of continental glaciation, until about 10,000 years ago. The subsequent flooding of this region has hidden whatever traces these early migrants may have left of their arrival on the threshold of the American continents, and it is necessary to look to the interior of North America for evidence of their presence. While these early horizons of American prehistory are little known, a

few sites from western North America have cultural remains or other possible evidences of man in a context suggesting occupation as early as 30,000 years ago. The best known of these is the Tule Springs site in southern Nevada, where crude chopper tools and scrapers appear to be associated with hearths and the burned and broken bones of extinct mammoth, camel, horse, sloth and a large bison (*Bison alleni*) nowhere else known to be associated with man. Radiocarbon samples from this site indicate a probable age of 28,000 to 32,000 years. At no site in this early context are there any types of implements distinctive enough to be recognized in a context of crudely chipped stone tools from later horizons.

The earliest well-defined cultures in the new world have been placed by radiocarbon dating at about 9000 to 10000 B.C. At this period, two distinct traditions in North America are known: the Paleo-Indian big-game hunters of the Great Plains and eastern North America, and the Desert culture peoples of the western basin-range region.

The oldest remains of the Paleo-Indian tradition are found on sites where large Pleistocene mammals were killed and butchered. The most distinctive artifact type of this horizon is the Clovis Fluted projectile point, a lanceolate point of chipped stone which has had one or more longitudinal flakes struck from the base of each flat face. These points are accompanied by side scrapers and, in one instance, by long cylindrical shafts of ivory. They are most frequently associated with mammoth, although associations with extinct species of bison, horse and camel have also been reported.

A second Paleo-Indian horizon, which seems in part to be contemporary with the Clovis material and partially to postdate it, is the Folsom phase of the central high plains. It is characterized by lanceolate points of more careful manufacture (including broader fluted surfaces) than Clovis, associated with the remains of extinct *Bison antiquus*. The Lindenmeier site, a Folsom camp site in northeastern Colorado, has yielded a wide variety of end and side scrapers, gravers and miscellaneous bone artifacts. Both Clovis and Folsom sites have been dated at about 9000 B.C. by radiocarbon. Fluted points similar to western Clovis specimens have been found over most of the eastern United States south of the limits of the last major glacial advance. A single series of radiocarbon dates from the Bull Brook site in Massachusetts places the age of points of this type at about 7000 B.C. in that area. However, the distribution of this artifact type with respect to glacial events dated by C^{14} suggests an appearance as early as 11000 B.C. and a terminal date near that of the Bull Brook site. In the east several specialized varieties of fluted points may replace Clovis-type points toward the end of the Paleo-Indian occupation. While there is no instance of the discovery of eastern fluted points in association with an extinct fauna, the similarity of the accompanying assemblages of scrapers and gravers to those of the western industries suggests a similar economic orientation in the east. Outside of the United States fluted points have been reported at scattered sites from Alaska to Ecuador; but no certain temporal context has been established for any of these finds, and faunal associations are not clear.

Another variety of Paleo-Indian culture which appears to be contemporary with the Clovis and Folsom phases is characterized in its early horizons by rather crudely flaked lanceolate points which have been found associated with the bones of mammoth at two sites near Ixtapan in the Valley of Mexico and between the Clovis and Folsom horizons in a gravel pit near Portales, N.M. Similar points in circumstances suggesting comparable age have been found at San Jon, N.M., and Lime Creek, Neb. It appears that by about 7000 B.C. the fluted-point industries were replaced by a succession of lanceolate point-using phases, which continued the Paleo-Indian hunting tradition, concentrating primarily on large, now extinct, species of bison until the onset of the Altithermal dry period about 5000 B.C. The eastern limit of these cultures is in the vicinity of the western Great Lakes, while the most intensive occupation was on the western plains.

The Desert culture tradition, an adaptation of food-collecting peoples to the impoverished habitats of the basin-range area of western North America, seems to have been well established by about 9000 B.C. The most extensive knowledge of this way of life comes from cave or rock-shelter sites, such as Danger cave in western Utah, in which the desiccated remains of vegetal and animal materials have been discovered with stone tools. The Desert peoples made intensive use of virtually all aspects of their habitat, specializing in the use of vegetable fibres for a wide variety of implements, including twine, nets, baskets, sandals and snares. Projectile points appear to have been mostly leaf- or lozenge-shaped or lanceolate in earlier phases, with a greater use of notching for hafting in later phases. An essential feature of Desert assemblages is the milling stone for use in grinding wild seeds. In earlier sites this is likely to be a small, thin portable slab of stone used with a small pebble handstone, while later in the sequence large basin-shaped milling stones are more characteristic. Large choppers and scrapers similar to artifacts from the early Tule Springs assemblage are common in Desert sites and appear to have been used for the processing of plant materials.

Although the southern limits of the Desert culture are not yet clearly defined, it is known that it extended into northeastern Mexico, where, in the state of Tamaulipas, Desert materials have been found associated with the earliest-known cultivated plants in the new world. Here, in the Infernillo phase, it appears that native American squash, peppers and perhaps beans were being cultivated as early as 6500 B.C. At this time domesticates formed only a small portion of the total diet, the bulk of which was derived from wild animals and, to a lesser extent, wild plants. At about 2500 B.C. a primitive variety of corn (maize) first appeared in the Tamaulipas area in the La Perra phase. It appears, however, that corn was first domesticated elsewhere, probably in the puebla area of south central Mexico, where a carbon-14 date of 3600 B.C. is reported from materials associated with early corn in a cave near the town of Tehuacan. Even in the La Perra phase, cultivated species formed only a small part of the total diet, the majority of foodstuffs being wild plants. Thus, there is evidence in the new world for plant domestication comparable in age to that of the old world but for many years this was unattended by the sequence of complex social developments that closely followed domestication there.

While the earliest cultivation was under way in Middle America, other areas of the new world also show evidence of interesting developments. At the site of Palli Aike, on the Strait of Magellan the earliest cultural horizon has yielded a radiocarbon date of about 8000 B.C., indicating that man reached the southern extremity of the new world well before 10,000 years ago. In the northern hemisphere, food-collecting cultures were well adapted to several specialized ways of life by about 4000 B.C. In the eastern United States, two basic traditions utilizing the woodland areas appear to have grown from an earlier culture which was present in that area by 6000 or 7000 B.C. This early Archaic tradition is best known from the Modoc Rock Shelter in southern Illinois and from Graham cave in Missouri and Russel cave in Alabama. It differs from preceding Paleo-Indian horizons in its orientation toward a broad range of resources, including plant foods, as evidenced by the frequent use of milling stones. While some projectile points from these sites suggest Paleo-Indian varieties, the majority are stemmed or notched and differ in flaking technique from contemporary western Paleo-Indian specimens. By 2500 B.C. the Archaic cultures of eastern North America had separated into several distinct phases. There appears to have been a major division between peoples adapted to a riverine environment in the south and those adapted to the lacustrine resources of the north. Both depended, to a large extent, on the forest resources bordering these aquatic habitats. The Middle Atlantic coast area appears to have supported another type of Archaic culture, and the boreal forests of the north yet another. In areas without concentrations of particularly favourable resources, a generalized Archaic culture similar to the earlier pattern seems to have persisted. Most Archaic cultures are characterized by a rather extensive use of ground-stone implements, both woodworking tools and other categories, such as bowls, knives, net sinkers and elaborate weights for spear throwers. Projectile points vary widely,

but are usually rather large and crude and are stemmed or broadly notched for hafting. Perhaps the most interesting of the late Archaic manifestations is the Old Copper culture of the northern Great Lakes area. Here, exposures of native copper were quarried and cold-hammered into implements, such as projectile points, knives, awls and axes; and highly valued copper from this region was traded over much of eastern North America.

In western North America, similar developments were under way during this same period. It appears that the more arid regions of the basin-range country were largely depopulated during the Altithermal dry period (from about 5600 to 2500 B.C.) and that in surrounding regions diversification and specialization took place. In the drainages of the major rivers of the northwest, such as the Columbia and the Fraser, the annual abundance of salmon was the basis of a cultural adjustment as early as 7000 B.C. Implements of this horizon are similar to those found earlier in the Desert culture with projectile points, the most diagnostic artifact types, tending to be long and leaf-shaped or slightly stemmed, with a few notched forms also present. Following the Altithermal drought, a broad horizon characterized by the use of indented-based points with serrate-edged blades (generally termed "Pinto-like" after the type locality in the Pinto basin of California) is found over much of the southern portion of western North America. In at least one of the phases representing this horizon, the Chiricahua of southern Arizona and New Mexico, it appears that primitive maize cultivation was practised. The site of Bat cave in western New Mexico has produced specimens of a type of primitive corn which is also known from the Flacco phase in Tamaulipas at 2000 B.C. but which is here in association with a Chiricahua assemblage from which materials have been dated at about 1000 B.C.

By 2500 B.C., techniques of cultivation had also reached the north coast of Peru where, at such sites as Huaca Prieta at the mouth of the Chicama valley, there was a mixed dependence upon marine foods such as sea urchins, mollusks and fish; upon wild plants, mostly tubers and roots; and upon cultivated plants, including beans, peppers and a different genus of squash than that cultivated in the early horizons in Tamaulipas. Gourds and cotton were also grown, the gourds for use as containers and net floats, and the cotton for twined fabric and cordage. The use of stone at Huaca Prieta is interesting in its simplicity. Crude flakes and shattered pebbles compose the entire chipped-stone industry, while pecked and ground-stone artifacts are chiefly perforated net sinkers. In the upper levels of the site are architectural remains consisting of one- or two-room, small cobble-walled subterranean houses. The absence of ceramics at the Huaca Prieta site poses a number of interesting problems. From the Valdivia site in Ecuador, several hundred miles to the north, C^{14} samples indicate that ceramics may have been present there as early as 2500 B.C., and another date from Panamá indicates that the ceramics of the Monagrillo phase were manufactured by about 2000 B.C. Our present knowledge of the north coast of Peru does not reveal ceramics before about 1200 B.C., indicating an isolation of this area from cultural developments to the north. With ceramics, maize and other indications of Middle-American influence appear in Peru.

The appearance of village farming in the upper levels at Huaca Prieta and in the immediately succeeding Guannape phase in surrounding areas is roughly contemporaneous with the first appearance of this way of life in the Valley of Mexico at such sites as Zacatenco and El Arbolillo. Here a relatively sophisticated ceramic tradition (clearly derived from elsewhere) appears in the earliest levels. While evidence for architecture is not completely clear, it appears that by about 1500 B.C. there were small villages of wattle and daub huts scattered along the shores of the lakes of the Valley of Mexico, with inhabitants subsisting largely on maize-bean-squash cultivation, supplemented by the meat of game animals and various aquatic resources.

Earliest evidences for the next cultural advances are apparent by about 800 B.C. in changes in architecture and settlement pattern in several areas of Middle America and Peru. At this time, fairly extensive public works are represented by temple structures and large sculptured monuments, which occupy a central position in towns and villages. Phases as widely separated as the Olmec of Veracruz and the Cupisnique of coastal Peru appear to be linked not only in time and patterns of basic subsistence but in specific ritual practices involving a jaguar or feline deity. Throughout Middle America and in the Andean area, this appears to have been a time of consolidation and establishment of the basic traditions which dominated the development of high cultures in the new world up to European contact.

The spread of cultivation into North America seems to have proceeded along two separate courses, one from northern Mexico into the southwest and the other from an unknown Middle-American source into the Mississippi valley. One of the earliest known phases in eastern North America in which maize cultivation appears to have had a role in subsistence is the Adena, which occupied the middle Ohio river valley by about 800 B.C. The stimulus of the Adena farmers was apparently instrumental in bringing about the spectacular Hopewell culture in the Illinois and Ohio valleys. The success of the Hopewell peoples (400 B.C. to A.D. 400) seems to have been due largely to their combining elements of the preceding Archaic cultures with elements of the Adena culture and perhaps with some features of a local cultivating tradition. It is evident that the Hopewell culture included a well-organized village-based society in which surplus resources were used in the construction of elaborate earthworks and were concentrated as wealth in a restricted group of individuals. The most outstanding feature of Hopewell culture is a burial complex which called for the deposition of concentrations of wealth in tombs of one or several deceased individuals. The interment procedure was elaborate and involved the construction of a large log tomb, later burned and covered by an earth mound. Artifacts found within these burial mounds indicate that the Hopewell were able to obtain goods from widespread localities in North America. Obsidian and grizzly-bear teeth were apparently derived from the Rocky mountain region; copper from the northern Great Lakes; and conch shells and other exotic objects from the southeast and along the coast of the Gulf of Mexico. The ceramics of the Hopewell appear to be based in two major traditions, one derived from northern Asia, which reached eastern North America by about 1000 B.C., and the other from Middle America, where the decorative technique of rocker-stamping, characteristic of finer Hopewell pottery, existed several hundred years prior to the earliest appearance of the Hopewell culture. In less favourable areas of eastern North America, a "generalized Woodland" culture paralleled the Hopewell in time, probably based more on collecting than on cultivation for subsistence.

The period of the Hopewell culture was followed by relative decline in social cohesion in the northern Mississippi and Ohio valleys, evidenced by the absence of unifying features comparable to the Hopewell in the succeeding generalized Woodland culture. At about A.D. 800 a new tradition, with much stronger and more specific Middle-American elements, moved up the Mississippi valley. This Mississippi culture was based on more intensive cultivating techniques than the Hopewell and resulted in impressive concentrations of population in large towns through the south and central Mississippi valley and in several areas of the southeastern United States. A central ceremonial plaza provided the nucleus of a Mississippi town, and each settlement had one or more pyramidal or oval earth mounds, surmounted by a temple or chief's residence, grouped around the plaza. This settlement pattern is typical of most of Middle America after about 850 B.C., but is not found in North America until the Mississippi culture appears. The scale of public works in the Mississippi culture can be estimated from the largest of the Mississippi earthworks, Monk's Mound near Cahokia, Ill., which measures 1,000 ft. in length, over 700 ft. in width and still retains a height of 100 ft. The first European explorers in the southern Mississippi valley in the early 16th century found the Mississippi culture still flourishing as warring alliances of towns, each ruled through an elaborate theocratic system based on kin ties.

In the southwest, the earliest villages of farmers appeared by about A.D. 200, and this initial development in southern New

Mexico and Arizona was succeeded by a gradual spread of this way of life as far north as southwestern Colorado, east to the Pecos river, and west into the lower valley of the Colorado river. The maximum expansion of the Puebloan culture of the eastern and northern portions of the southwest appears to have taken place by A.D. 1150 or 1200 and was followed by the gradual abandonment of much of the area by farming peoples. This decline seems to have been due to a combination of factors, including drought, deforestation and lack of social cohesion within the villages. At the time of historic contact the Puebloan peoples were restricted to the Rio Grande valley and adjacent localities and to scattered settlements in west-central New Mexico and on the Hopi mesas of Arizona. The early explorers encountered other less well-organized farming groups, descended from the Hohokam and Patayan traditions of the southwest, in scattered localities along the Gila, Salt and Colorado rivers.

In South America, little is known of cultural development outside the Andean area, where, as in Middle America, urban civilization was well under way by the first few centuries A.D. From a sequence near the mouth of the Orinoco, it appears that manioc cultivation, which formed the subsistence base for stable villages in the tropical forest, had been developed by about 1000 B.C. Peripheral to the Andean area numerous cultures are known, particularly in Colombia and northern Argentina and Chile, which show marked influence from Andean urban centres and yet preserve distinct local traditions throughout the late prehistoric period.

An over-all view of the prehistory of the new world prior to the development of urban civilization reveals several general trends. The outline above follows the forefront of cultural development as it took place in several well-known areas. In localities less favourable to primary or intensive cultivation, the level of cultural development tended to stabilize at the point at which maximum food production was possible with the techniques at hand. Thus, in the arctic and in the boreal forests of the north, as well as through most of the southern South America and various other regions unfavourable for cultivation, cultural activity remained at an Archaic food-collecting level through the entire prehistoric period. In the tropical forests of South America and the woodlands of the northeastern United States, farming villages were the apex of cultural development under prehistoric conditions. In relatively favourable areas, such as the Mississippi valley, the oasis regions of the southwestern United States, and several other regions peripheral to the South and Middle American high-culture centres, temple-centred towns were the climactic development. A general appraisal of cultural complexity reveals a trend from a single, or few early cultural phases of uniform composition covering the entire new world, to the extremely diversified cultures of the last two millenniums of the prehistoric period. Within the sequence of cultural development it appears that the greatest diversity is present at the village-farming level, with hundreds of distinct phases indicating essentially locally oriented social groups which gradually united into larger units as communication and political pressures from more successful centres submerged the cultures of the weaker local phases.

When compared with the old-world sequence, a similar succession of cultural levels can be distinguished in the new world, but there are differences in such basic qualities as the lack of economically important domestic animals in the new world and the much greater diversity of habitats and forms in which the various cultivated plants originated. These factors seem basic in explaining the wide discrepancy in rapidity of cultural development between the old and the new world once the idea of cultivation was present. It was not until several cultivated crops (corn, beans and squash for most of the new world) were fully developed and assembled that higher cultural levels were possible.

D. CIVILIZATIONS

It is customary to regard the time span of western civilization as immensely long, extending back through medieval Europe to the Greco-Roman world and to still earlier oriental forerunners. But the length of time for this development is probably no greater than that which had elapsed between the prior introduction of agriculture and the rise of the first civilized states. And both of these intervals together probably constitute only about one-fiftieth or less of the time since two-legged, tool-using creatures made their first appearance. Furthermore, the extensive spread of civilization is much more recent still. Civilizations have prevailed over uncivilized food collectors, nomads and primitive farmers across most of the world only within recent centuries. Thus, it must be stressed that civilization is a late condition in the human record.

Since at least the days of L. H. Morgan (1818–81), the achievement of civilization has been widely recognized as a major stage in man's social and cultural evolution. Coming ultimately as a consequence of the attainment of settled food production, its main attributes were substantial, qualitative increases in the scale and complexity of the limited number of societies which were its initial representatives. As there is civilization, so there are civilizations. And at least until well after the end of prehistory by any definition, the early civilizations must be regarded as very limited enclaves in a largely uncivilized world.

The earliest civilizations of the old world occupied the great alluvial valleys of the near east by around 3000 B.C. There is some evidence that Egyptian developments were stimulated by Mesopotamian influences, but the beginnings of civilization in the two areas were nonetheless essentially independent of one another and more or less contemporaneous. Farther to the east, civilization made its appearance in the valley of the Indus river a half millennium or so later. Here it was also essentially independent in at least its stylistic manifestations, but the time lag and the apparently abrupt inception of urban life—abrupt, that is, relative to that in Mesopotamia—suggest that stimulus from the latter area played a considerable part in its origin. The civilization of north China, still farther afield, did not cross the same threshold until after the middle of the 2nd millennium B.C., and controversies continue regarding the role of the already well-established near eastern civilizations in its formation. From these four primary centres, lesser and later centres naturally developed across the Eurasiatic hinterland. However, this process of consolidation and expansion is a part of the historic and not the prehistoric record.

A direct comparison of the old-world sequence with that of the new world is complicated by somewhat different cultural emphases. But while criteria for the identification of early civilization in the two hemispheres are not entirely the same, most authorities would concur in assigning the first appearance of a civilized way of life in the new world to the final centuries of the pre-Christian era. In view of the evident delay in this achievement, the possibility that it was prompted by influences from eastern Asiatic centres has long been debated. Apart from a few isolated and somewhat dubious cultural elements, however, the general course of development was sufficiently different in the new world to indicate that it was essentially independent of external stimuli.

Two centres or focuses of early civilization in the new world came into existence roughly at the same time, in Middle America and in the central Andes. Stylistic affinities suggest the possibility of a brief period of interconnection between them at the outset, perhaps the result of the southward spread of an early Mesoamerican cult. As in the case of Egypt and Mesopotamia, however, the subsequent development of the two major focuses proceeded along substantially independent lines. As late as the time of the Spanish conquest in the 16th century, the powerful Mexican and Inca empires had little or no direct knowledge of one another.

Civilization is of concern in the present context, of course, only as the terminus of the long prehistoric record. In most areas the rise of civilization coincided at least roughly with the development of writing, so that the later courses of civilization are illuminated by historical sources. In the absence of documents, the limitations of purely archaeological sources entail a stress on certain aspects of the rise of early civilizations—primarily those

involving formal governmental or religious institutions, and the material-technical facets of culture more generally. To be sure, a comparison with civilizations which have left written records, and with nonwestern civilizations of today, suggests many other dimensions in which the early civilized societies must have diverged from their predecessors and noncivilized contemporaries. Robert Redfield, for example, has identified the rise of civilization primarily with the formation of great traditions which systematized and redirected the cultural and moral order as it had been previously conceived in scattered folk communities. But except as indirectly inferred from objects associated with ritual, or from tenuous parallels with modern nonwestern societies, such a dimension of change as this is virtually irrecoverable by the prehistorian.

The possibility of attaining a civilized way of life rested ultimately on conditions which only intensive agriculture made possible. Among these were storable food supplies permitting permanent residence, agricultural surpluses supporting the proliferation of full-time administrators and specialists freed from primary subsistence activities, and a sufficient intensity of production within a given area to encourage the formation of urban centres. Recognizing these as prerequisites for civilization, V. Gordon Childe has formulated the growth of civilization as the consequence of two successive revolutions. The first, or neolithic revolution, has been dealt with in a preceding section; it encompassed the domestication of the plants and animals essential for an agricultural mode of subsistence, as well as the formation and spread of settled village communities. For the second, or urban revolution, a number of criteria have been proposed. Most importantly, these include: (1) cities, or large, dense settlements; (2) the differentiation of the population into specialized occupational groups; (3) social classes, including a ruling stratum exempt from primary subsistence tasks; (4) mechanisms for extracting a "social surplus," such as taxes or tribute; (5) monumental public buildings and other enterprises; (6) writing.

It is important to note that these two proposed revolutions differ fundamentally in character. The first represented most importantly an advance in man's control of his environment and consisted of a series of discoveries permitting its vastly fuller exploitation. The urban revolution, on the other hand, affected man's relation to his environment only secondarily and much more slowly. As agricultural techniques became stabilized, the crucial changes increasingly were those in community size and composition, in the appearance of new institutions and in the vastly greater complexity of patterns of social organization. These are changes less in man's interaction with his habitat than in that with his fellows. Hence, different interpretive skills are required to elucidate them than to explain the changes which accompanied the beginnings of agriculture, skills rooted more in the social sciences and humanities than in the natural sciences. Moreover, because of the increasing diversity of the social and cultural scene, our understanding of these changes is increasingly subject to distortions arising from the accidents of preservation or the unrepresentativeness of evidence so far obtained. The preoccupation of archaeologists with late pre- and protohistoric temple furnishings and architecture, for example, probably has exaggerated the importance of temples and certainly has left us with disappointingly little information on the nature of contemporary secular life in neighbouring precincts of the same towns. By contrast, it can be (or at least, has been) generally assumed that the relative absence of social and cultural differentiation in early villages permits them to be adequately sampled by random small-scale soundings.

If we accept the general descriptive validity of the criteria for civilization given above, the identification of the rise of civilization with the sequence of a neolithic and an urban revolution is still subject to three important qualifications. In the first place, to say that civilization depends on agricultural surpluses is not the same as saying that agricultural surpluses were all that was necessary to bring civilization into being in any given area. There is simply not enough known of the productivity of prehistoric agriculture to indicate whether increasing surpluses might have triggered subsequent changes in other aspects of culture. In fact, on the basis of present evidence it seems at least as likely that it was primarily through changes in social organization which civilizations brought about that there were advances in agricultural productivity. Second, it must be stressed again that the criteria given above are only those that are in some way accessible to the archaeologist. The tendency to regard them as a self-contained list which somehow defines civilization, or even which somehow embraces its primary causes and consequences, must be avoided. Third, the term "revolution" implies sudden and violent change. Yet, if the rise of civilization was undoubtedly rapid as compared with the hundreds of thousands of years of preagricultural life, it is equally clear that it was spread over many generations and probably never was as apparent to its participants as the Industrial Revolution has been to recent generations. Authorities are not even agreed, moreover, that the neolithic and urban revolutions were events separable in time. It remains only a hypothesis that one was consummated before the other began, and an equally plausible hypothesis might see a single, rising tempo of change that began with incipient agriculture and culminated in the appearance of oriental Bronze Age monarchies.

There remains a further difficulty with the criteria mentioned earlier: they apply most usefully to the earliest or "type" sequence in Mesopotamia, and elsewhere diverge to a greater or lesser degree from the observed archaeological data. The Maya area of Mesoamerica, for example, lacked true cities yet exhibits the other elements in the list to such a degree that its status as a civilization seems indisputable. According to some scholars, cities were also absent in Egypt during the Old Kingdom, although the other appurtenances of a civilized state are unusually well represented there. Similarly, the highly organized Inca empire got along entirely without writing, while in the Mayan and Mexican areas the much earlier invention of writing was only applied to economic and administrative tasks in the centuries immediately preceding the Spanish conquest.

To phrase the problem more broadly, the separate focuses of early civilization tended to crystallize into patterns which in some respects are quite different. Mesopotamia was characterized by extensive irrigation agriculture, by fairly rapid technological progress (though hardly rapid enough to "explain" the more profound social changes that took place concomitantly), by emphasis on urban settlement, and by an early separation between the temple cults and the political leaders. In Egypt, we find irrigation agriculture again and an even more precocious elaboration of a state administrative apparatus, but there is an absence of the trends toward rapid technological advance, urbanization and secularization that are so evident in Mesopotamia. A further variation on this pattern is found in the Maya area, where agriculture was largely of a nonintensive slash-and-burn variety, where the bureaucracy of a centralized state was entirely absent and where primary cultural emphasis seems to have been placed on the elaboration of esoteric cults by hierarchies of priests for whom important nonreligious functions in the society are not apparent. Peruvian civilization, on the other hand, was somewhat closer to the Mesopotamian model, except perhaps in its greater emphasis on an ethnically distinguished ruling stratum. In both new-world civilizations, but in neither of those of the old world, it might be added, there are indications that monumental temple architecture long preceded the other criteria of civilization—and in fact may be as old as the earliest village settlements based on agriculture.

These divergences should not be taken to deny the regularities that are implied by Childe's criteria for the urban revolution. Given a sufficient level of abstraction, the early civilizations of both hemispheres shared most of their essential features. And certainly they constitute a distinctive sociocultural type when contrasted with all earlier folk societies. They form the culminating stage of the prehistoric record, and it is worth noting in conclusion that their essential attributes never subsequently disappear. In fact, in one sense the world's written history is the documenting of their spread: gradually and irregularly, based on a succession of different focuses (of which western Europe and the United States are only the most recent), but ultimately ir-

resistible.

IV. EGYPT AND WESTERN ASIA

A. EGYPT

The scholars who accompanied Napoleon to Egypt began the modern archaeological study of that country, although hampered by the fact that they did not understand the ancient language. When Jean François Champollion succeeded in deciphering the hieroglyphic text of the Rosetta stone in 1821–22, rapid advances were soon made in the translation of Egyptian texts. The 19th century also saw the formation of collections of antiquities and the first accurate copying of the monuments. Some excavation was undertaken by Auguste Mariette, who founded the antiquities service and the Cairo museum. However, scientific excavation was a development of the 20th century, based on methods devised by Sir Flinders Petrie and developed by such men as Ludwig Borchardt, George Andrew Reisner and Herbert Winlock. In conjunction with this field work immense contributions were made by the philologists Adolf Erman, Kurt Sethe, F. L. Griffith and Sir Alan Gardiner and by the historians Gaston Maspero, Eduard Meyer and James Henry Breasted.

Historic Egypt emerged in the 1st dynasty with a developed hieroglyphic writing and a brilliant display of technical skill. The magnificent objects excavated by Walter B. Emery and Zaki Saad in the Sakkara (Saqqara) and Helwan cemeteries of the Memphis district lend a new meaning to the fragmentary material known earlier from the shrine at Hierakonpolis and the Abydos royal cemetery in upper Egypt. Skill in the minor arts was accompanied by a dexterity in the working of large blocks of stone to line the burial chambers at Helwan which shows that tradition was correct in attributing this craft to Memphis. Certainly the first great building of stone was erected at Sakkara. There, in the temples of the Step Pyramid which Imhotep built for King Zoser in the 3rd dynasty, the excavations of C. Firth and J. P. Lauer show that an earlier architecture of light materials was literally translated into stone forms. This building was, in turn, a step in the development of Old Kingdom architecture.

The chronological divisions of Egyptian history are taken from the dynastic Lists of the Ptolemaic historian Manetho. These were based on earlier king lists such as the Turin papyrus of the 19th dynasty. Fixed dates have been calculated from records of astronomical observations and give 1991 B.C. for the beginning of the 12th dynasty and 1570 B.C. for the commencement of the 18th. The Turin papyrus states that the 11th dynasty lasted 142 years and that 955 years elapsed between Menes, the first king of the 1st dynasty, and Aba, the last king of the 8th. The length of the 9th and 10th dynasties remains uncertain, but a date of about 3200 B.C. can be estimated for the beginning of the 1st dynasty, with the possibility that this may have to be lowered.

The Archaic period (1st to 3rd dynasties, 3200–2680 B.C.) was followed by the Old Kingdom or Pyramid Age (4th to 6th dynasties, 2680–2258 B.C.). The First Intermediate period (2258–2052 B.C.) included the 9th, 10th and part of the 11th dynasties. The Middle Kingdom began in the 11th dynasty with the uniting of Egypt under Thebes in 2052 B.C. and ended with the 12th dynasty in 1786 B.C. It was followed by the Second Intermediate period (13th to 17th dynasties). The New Empire commenced with the 18th dynasty in 1570 B.C. and closed with the 20th about 1085 B.C. Then came a late period (21st to 31st dynasties), which was interrupted by the conquest of Alexander in 332 B.C.

Annual Nile floods have produced conditions which militate against the kind of stratified excavation of a city mound practised in other countries. Excavation has mostly been confined to the cemeteries on the edge of the desert. House architecture has survived at a few sites, such as Ikhnaton's city at Amarna, which lay beyond the reach of the floodwaters. So much material from tombs might have produced a distorted picture were it not for the Egyptians' belief in the continuance of life after death. This led them to bury with the dead their personal possessions, to represent different phases of daily life on the chapel walls and to make statues of the owner of the tomb.

Old Kingdom.—A wonderful picture of the Old Kingdom at its height in the 4th dynasty has been gained from the excavations at Gizeh of Reisner and Hermann Junker. That a vital formative period lay between the Step Pyramid of Zoser and the Great Pyramid of Cheops (Khufu) at Gizeh was long evident from the pyramids at Medum and Dahshur and the private tombs with reliefs and statues such as those of Rahotep and Nefert or paintings like the famous Medum geese. This transition from the 3rd to the 4th dynasty was clarified by Ahmed Fakhry's excavations at Dahshur, where royal statues and reliefs were finally found in the temples of the Bent Pyramid built by Snefru, the first king of the 4th dynasty. It is possible, then, to follow the steps by which the Old Kingdom achieved a truly monumental style in architecture and to obtain an impression of how the sculptor realized a noble conception of the human figure through a particularly happy blend of naturalism, mastery of simplified form and sensitive feeling for material. The finest 4th-dynasty sculpture reveals an interest in portraiture that was rivaled only by certain 12th-dynasty royal heads and a few statues of the late period. The fine cutting of the reliefs had a parallel only in the royal work at the beginning of the 5th dynasty. The gold-cased furniture of Hetepheres, wife of Snefru and mother of Cheops, shows that the same superlative craftsmanship was lavished on the dwellings

The large number of workmen trained in the vast projects of the 4th dynasty made technical skill more widely available in the 5th and 6th dynasties, as is abundantly illustrated by the work of the German expedition at Abusir and that of the Egyptian antiquities service at Sakkara. Royal monuments decreased in size but were more extensively decorated. The simple severity of earlier representation gave way to a more descriptive style which illustrates delightfully the life of the Old Kingdom. Even the lesser official could command a surprisingly high standard of craftsmanship. However, the brilliance of the Memphite court begins gradually to be dimmed by the rise of a provincial nobility whose rock-cut tombs appear near their capitals as far south as Aswan.

Written records remained somewhat laconic in the Old Kingdom, although the magical spells of the pyramid texts inscribed on the walls of royal burial chambers furnish a wealth of information concerning early religion. There were brief biographical inscriptions, royal decrees and records of expeditions to the stone quarries or for foreign trade. Notations of certain historical events survived in the fragmentary annals of the Palermo stone and its related pieces. A few letters on papyrus have been recovered, while the precepts of wise men such as Hordedef and Kagemni were repeated in later literature.

Middle Kingdom.—The collapse of the centralized administration brought an end to this prosperous civilization based essentially upon an agricultural economy. The ensuing chaos is reflected in a pessimistic literature that looks back upon this troubled time from the renewed stability of the Middle Kingdom. The poverty of the disunited segments of the country is clear from the poor craftsmanship and clumsy inscriptions of the tombs found in upper Egypt at sites such as Dendera and Naga-ed-Der. The growth of Theban power in the 11th dynasty is richly illustrated by H. E. Winlock's excavation of the Mentuhotep cemetery at Deir el Bahri. Inscriptions there and at Asyut tell of the struggle between the south and the north from which Mentuhotep II emerged triumphant over Heracleopolis to rule a newly united kingdom.

The strong rulers of the 12th dynasty established their capital in the north and, imitating Memphite custom, were buried in a series of pyramid fields stretching from a little south of Sakkara to the mouth of the Fayum, at Dahshur, Lisht, Lahun (Illahun) and Hawara. The excavations of the Metropolitan Museum of Art (New York city) at Lisht have built up a series of archaeological material comparable in completeness with that supplied

by Gizeh and Sakkara for the Old Kingdom. The craftsmen of the court drew upon Memphite models, but elsewhere in the country there is a regional diversity which stems from the feudal character of the First Intermediate period. The great men of the provinces decorated imposing tombs in the neighbourhoods of their chief towns. There appeared a variety of styles, both in wall decoration and sculpture in the round, unknown in the Pyramid Age. In these provincial tombs the painter developed an increased facility. The same delicacy and technical skill entered into the making of jewelry for the court at Dahshur and Lahun. Such pieces were imitated at Byblos on the Syrian coast, where there appeared a skilled metalworking industry that was to have a long tradition. Somehow related to the Syrian crafts and the importation into Egypt of Cretan painted pottery is a use of new decorative patterns in Egypt employing interweaving spirals and the palmette.

New forms appeared in architecture, as in the Theban temple of Mentuhotep II, which combined terraced colonnades with the pyramid form. Some traces have also survived of temples of a nonfunerary character. Sculpture in the round seldom attempted the harmonious forms of the Old Kingdom. It is as though the sculptor, like the writer, could not regain the calm confidence of the Pyramid Age. The careworn faces of Sesostris III (Senusret) and Amenemhet III reflect the bitter disillusionment seen in the literature. This tentative effort to portray inner feeling is one aspect of an advance in social consciousness which is evidenced in literature by a new concern for the rights of the individual man. These ideas are more fully expressed in writing than were the simple precepts of an earlier time. Similarly, the more flexible language of the *Tale of Sinuhe* lends colour to the background of the story. There is evidence, too, of a wider interest in foreign lands, supported by material excavated in Syria, Palestine and Crete, as well as the trading post at Kerma in the Sudan.

New Empire.—A disintegration of central power in the Second Intermediate period was complicated by the invasion of the Hyksos, who entered Egypt from Palestine. Except that they introduced the use of the horse and chariot, there is still more conjecture than conclusive fact concerning this people, in spite of the excavation of their encampments in Syria, Palestine and the Egyptian delta. Inscriptional evidence is very scanty. A strong Theban family again began the liberation of the country in the 17th dynasty. The New Empire inherited an aggressive foreign policy which resulted in an extensive empire. As this empire declined there came a shift to defensive measures. In the 19th and 20th dynasties Merenptah and Rameses III drove off the "peoples of the sea," but later invasions succeeded, first from Kush in the south and then by the Assyrians, Persians and Greeks.

Until the conquests of Tuthmosis III, the early 18th dynasty showed at Thebes a clear continuance of old tradition. Its finest monument, the terraced temple of Queen Hatshepsut at Deir el Bahri, was reconstituted by Edouard Naville, Winlock and the architects of the antiquities service. The early buildings of the Karnak temple and the paintings in the tombs of the Theban nobles complete this picture of a renewal of old forms, as yet unaffected by the complexity of new currents. The effect upon the Egyptian of his dominant position in a greater world can be traced through changes in subject matter and style in the tomb paintings and in the increasing size and ostentation of the temples. The altered spirit is vividly displayed in the painted decorations of the palace of Amenhotep III at Thebes and in his son's new town at Amarna. A delight in curving lines and luxurious decorative detail was combined with a love of precious small objects for their charm alone. This is fully illustrated by the amazing tomb equipment of the young king Tutenkhamon. The art of the Amarna period, although powerfully affected by the monotheistic tendencies of Ikhnaton's brief religious revolution, is an equally true reflection of the spirit fostered by the empire. The rich finds made by Petrie, Borchardt and John Pendlebury at Amarna show also that Ikhnaton's artists produced the only true portrait sculpture of the New Empire. In general, though, painting seems to have been the most congenial medium of expression and reaches the height of its development in the 18th dynasty.

All the complexity of New Empire life is documented by written evidence. Accounts of military campaigns, foreign office archives, legal and administrational records are supplemented by biographical inscriptions, popular tales, poetical compositions, treatises on mathematics and medicine and a vast religious literature. These can be brought into relation with an increasing body of such material from neighbouring countries.

Later Empire.—The funeral customs at Thebes in the later empire can be studied in detail as the result of the excavations of Bernard Bruyère at Deir el Medineh, while the royal burials of the 21st and 22nd dynasties found by Pierre Montet at Tanis in the delta rival in splendour those of an earlier time. That the craftsman had lost little of his old skill is clear from these Tanis objects and those found by Reisner in the tombs of the 25th-dynasty Kushite kings and their successors in the thoroughly Egyptianized Sudan. On the other hand, Theban painting declined sharply in the 19th dynasty and soon virtually disappeared. There was a renewal of creative effort under Rameses III which is evident in the reliefs of the Medinet Habu temple. From the 20th dynasty onward, accounts of criminal investigations illustrate the corruption creeping into civil life, while the drawings of satirical papyri mock the manners of the period. The contemptuous treatment of Egyptians abroad is evident from Wenamon's account of his attempt to fetch timber from Syria early in the 21st dynasty.

The increasing importance of the delta encouraged the division of the country, which split into small sections under struggling petty dynasts in the 22nd to 24th dynasties. The success of one of these men, Tefnakht of Sais, seems to have provoked the invasion of the Kushite king Piankhi. The Kushite 25th dynasty brought a renaissance of Egyptian spirit which survived Assyrian attack to continue under the Saite 26th dynasty. A vigorous school of portrait sculpture appeared and a new freshness is felt in the tomb reliefs. Simultaneously there was an archaizing return to ancient forms in writing and in art. Egypt preserved its old ways with remarkable tenacity in spite of close political contact with the Mediterranean world and western Asia. Assyrian and Persian rule left scarcely a perceptible mark, while the new spirit carried abroad from Greece by traders and mercenaries in Saite times met with a stout resistance which continued even after the time of Alexander the Great.

B. Mesopotamia

In contemporary archaeological usage the name Mesopotamia is generally applied to the region of western Asia which is dominated by the river valleys of the Tigris and the Euphrates. This region is bordered on the east by the Zagros mountains, on the west by the north Syrian desert plateau, on the north by the Kurdish mountains and on the south by the Persian gulf. Its boundaries roughly coincide with those of the modern kingdom of Iraq. Geographically, as well as historically, Mesopotamia falls into two distinct parts: the north, which is geologically the older, consists of rolling country that extends south as far as Hit and Samarra; the south, geologically the more recent, is the flat alluvial plain which extends down to the Persian gulf. As in the tradition of the Old Testament, north and south Mesopotamia are often referred to as Assyria and Babylonia, respectively.

Exploration.—The Old Testament was, indeed, for many centuries the main source of information about ancient Mesopotamia available to the western, European, world and the main stimulant for interest in that region. Biblical associations dominated the interest of early European travelers and explorers in

Mesopotamia. During the middle ages, few Europeans ventured into this relatively remote, inaccessible and inhospitable region. One of these was a Spanish-Jewish traveler of the 12th century, Benjamin of Tudela. Though his main interest was the status of the Jewish communities in the countries that he visited, he mentions the ruins of Babylon and correctly places the ruins of Nineveh across the Tigris from Mosul. Not until after the Renaissance with its awakened interest in classical antiquity did Europeans begin to take interest in the antiquities of Mesopotamia, and even then the interest was biblical rather than historical and archaeological.

From the end of the 16th century onward, the number of Europeans who visited Mesopotamia increased steadily. The Roman nobleman Pietro della Valle seems to have been the first to bring samples of cuneiform writing to Europe. These were stamped bricks which he collected in 1616 and 1625 in the vicinity of Babylon and Ur. The majority of travelers during the 17th and 18th centuries seem to have been British, followed in number by French, but Scandinavian and other European countries were also represented. The travelers included scholars, clergymen, merchants, government officials and diplomats. In the 18th century an increasing number were more than casual visitors. Several spent many years in Mesopotamia, sometimes on repeated visits and often pursuing definite scientific, commercial or political objectives. More and more came equipped with a knowledge of oriental languages and with experience gained during sojourns in other parts of the orient.

The establishment of offices of the British East India company in Basra and Baghdad, with their permanent representatives, and the establishment of British and French consulates in Mesopotamia played an important part in the archaeological exploration of the country. One of the residents of the East India company in Baghdad, Claudius James Rich, was in many respects the pioneer of methodical antiquarian exploration of the region.

Early in the 19th century, a point had been reached when explorers were no longer satisfied with a topographical study of the ruins which they visited nor with collections of antiquities which could be gathered on the surface or obtained from local inhabitants. Occasionally trenches were dug into the ruins in the hope of enriching these collections. Most of these activities took place in the south. The sporadic diggings were usually on a small scale and did no great damage except as setting an example for the local inhabitants, who then gradually became aware of the monetary value of the antiquities which lay buried in the ruins.

Excavations.—The era of regular archaeological excavations was opened in 1842 by the French consul in Mosul, Paul Émile Botta, who began his activities at Nineveh but soon transferred them to Khorsabad, where he discovered and began the excavations of the palace of Sargon II (722–705 B.C.). Hampered by local Turkish officials, he appealed to the French minister in Constantinople and obtained a royal permit—a firman—from the sultan for the continuation of his dig. Thus the precedent was established for the official permit or concession that is needed for archaeological excavations in near eastern countries. After a short interval, excavations were resumed at Khorsabad under the direction of Victor Place with Félix Thomas as architect and artist. The British followed almost at once with excavations at Nineveh and Nimrud under the direction of Sir A. H. Layard.

The results of both enterprises far exceeded all expectations. During the first decade of regular excavations, the French and the British discovered palaces of Assyrian kings, which were decorated with thousands of bas-reliefs depicting the daily life of the Assyrian court, with coloured glazed bricks and paintings, and which contained innumerable small objects. These finds laid the foundations for the magnificent collections of Mesopotamian antiquities in the British Museum and in the Louvre. Less spectacular but no less important was the discovery of a wealth of inscribed material, especially the library of Assur-bani-pal at Nineveh. At the same time, efforts to decipher cuneiform (*q.v.*) script were crowned with success as a result of the perseverance and ingenuity of scholars of several nationalities. Thus, when the magnificent results of the first decade of regular excavations became available, a new branch of scholarship, Assyriology, was ready with scholars to take over the study of the inscriptions.

The first outburst of archaeological activity in the north soon subsided, though exploration and excavation on a smaller scale continued. Gradually the centre of interest shifted back to the south, where both the British and the French undertook small-scale investigations. In the south too the French were the first to establish a regular expedition, when the French consul at Basra, E. Chocquin de Sarzec, in 1877 identified Telloh (ancient Lagash) as the source of statues of a hitherto unknown type. Work at Telloh continued intermittently until 1935.

Toward the end of the 19th century, German and U.S. scholars joined the British and the French in the field. The U.S. effort was on a relatively small scale and of short duration. The Germans, on the other hand, developed their activities to include several sites, in both the north and the south, among them the famous sites of Ashur and Babylon (*qq.v.*). Indeed, early in the 20th century, in the years preceding World War I, the Germans were in the fore of archaeological activities in Mesopotamia.

World War I caused an interruption of archaeological activity, but with the British occupation of Mesopotamia work was soon resumed. The British organized and guided a department of antiquities and a national museum in the newly established kingdom of Iraq, which was under their mandate.

In the years between World Wars I and II archaeological excavations in Mesopotamia were conducted by British, French, U.S., German and Italian institutions. During that period the U.S. activities gained first place in terms of number of sites excavated and results obtained. Because of the magnitude of the task, often too large for a single institution to undertake, the Americans introduced joint expeditions, in which excavations were sponsored by two or more institutions. Participants were either U.S. or U.S. and British institutions. Interest extended beyond the periods of classical Mesopotamian civilization to prehistoric periods.

The peak of archaeological activities in Mesopotamia was reached in the middle 1930s. Political tensions in Europe and the near east combined with the effects of the economic depression in the United States caused a gradual decline of these activities, which finally came to a standstill. When World War II broke out, not a single foreign expedition was active in Iraq.

During World War II, excavations in Mesopotamia did not cease completely. The department of antiquities, organized and developed by the British during the period of the mandate, was able to undertake a number of important excavations on its own. After the war, excavations in Mesopotamia were resumed on a relatively small scale. U.S. and British institutions were the first in the field and were followed by the Germans in 1953. The principle of joint expeditions was maintained, and the effort was again divided between historical and prehistoric sites. It was significant that, except for new prehistoric sites, archaeological activity was concentrated on previously excavated sites. The British returned to Nimrud, the very first site on which they undertook regular excavations more than a century before, the Americans were digging at Nippur, the first site dug by a U.S. expedition more than 50 years earlier, and the Germans had returned to Erech (modern Warka), where small-scale digs were undertaken by W. K. Loftus in 1849 and 1854 and where a regular German expedition was established in 1912. This was not only a striking reminder of the seldom realized fact that not a single ancient site of any importance had as yet been completely excavated but also a reflection of the progress which archaeology had made as a scholarly discipline.

Stratigraphy and Relative Chronology.—In contrast with Egypt, where ancient sites often contain remains of various periods at the same level near the surface, and where many monuments, such as the pyramids and the great temples, have never disappeared from sight, the ancient sites of Mesopotamia usually consist of accumulations of superimposed ruins of consecutive occupations, and all the ancient monuments have to be uncovered by means of excavations. This contrast is due to differences both in building material and in geographic and climatic conditions.

In Egypt a great variety of hard stone suitable for monumental

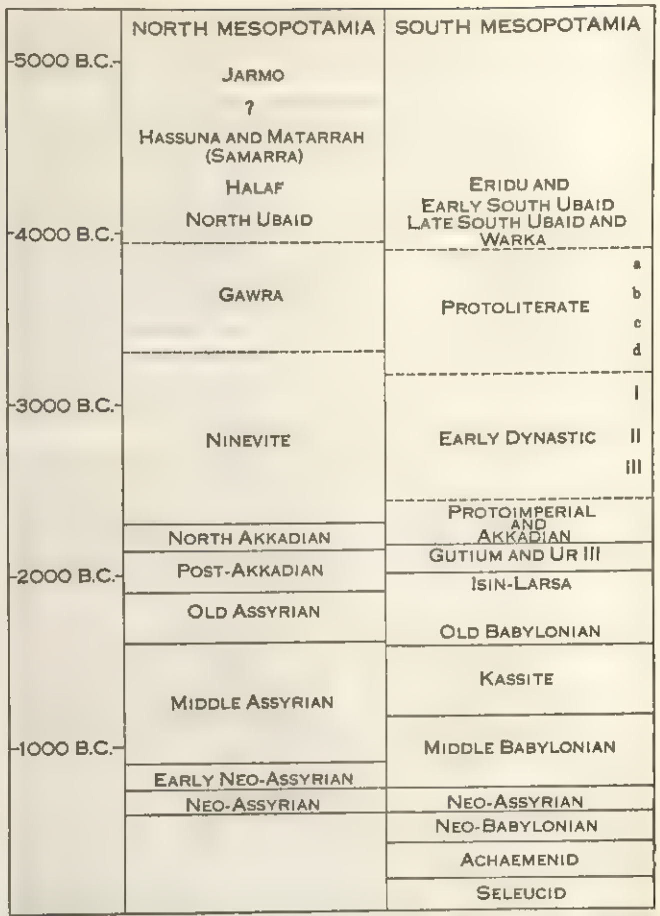
building always was available. In Mesopotamia, on the other hand, stone had to be imported from relatively great distances, and the universal building material in all periods was the indigenous and ubiquitous alluvial clay. Adobe, then, was the prevailing building material in Mesopotamia at all times and for all purposes, from the humblest private dwelling to temples, palaces and colossal city walls many yards thick. Adobe structures crumble easily when exposed to the elements. This feature and the cheapness of the material were conducive to relatively frequent repairs and rebuildings. In the process of rebuilding, earlier debris was simply leveled off and new buildings were erected on top of it. The results of such accumulation are the artificial mounds for which the Semitic languages from earliest times have had a specific name—"tell." Most of the tells are thus stratified, with, generally speaking, the lower strata being earlier than those above them. One of the preoccupations of the modern excavator is to distinguish between the strata and to attribute the finds to their proper strata in order to establish the relative chronology.

Not all ancient sites were occupied continuously and during the same periods, and consequently gaps in cultural sequence may be encountered in the course of excavations. Such gaps in one site may be filled through information obtained on others. Synchronization of archaeological strata on different sites is based largely on typological comparisons of finds in them.

The development and changes in the various classes of archaeological material in the course of time serve as the bases for distinguishing and defining the various earlier archaeological periods. For later, historical, times, periods are defined chiefly on the basis of written documents, and the archaeological materials must be co-ordinated with historical evidence. A summary of the main archaeological and historical periods in Mesopotamia is given in the accompanying chronological chart. An attempt has been made also to correlate these periods in terms of absolute chronology.

Absolute Chronology.—Absolute chronology can be established in various ways, the most widely used being direct reckoning from a previous dated event. This method is valid in Mesopotamia only for the Seleucid era, at the end of the 1st millennium B.C. For earlier periods, absolute chronology depends on chronological lists such as king lists which give regnal years or on lists of eponymous officials (limmu lists). The reliability of a chronology established on the basis of such lists depends on their accuracy and continuity as well as on the possibility of establishing certain absolute dates within them. The latter can be achieved either by means of synchronization with dated events in other regions or through astronomical calculations. The astronomical method depends on a specific astronomical event having been accurately observed and recorded in ancient times. Such is the case of the eclipse of the sun which was recorded in an Assyrian limmu list and which has been calculated to have occurred on June 15, 763 B.C. This astronomical synchronization is the basis for the absolute chronology of the first half of the 1st millennium B.C. and, with a certain margin of error because of discontinuity in the list, of the second half of the 2nd millennium B.C.

The absolute chronology of the first half of the 2nd millennium B.C. depends largely on another recorded astronomical event, namely the heliacal setting and rising of the planet Venus. Since astronomical events are periodical in character, additional criteria must be used for determining the particular event recorded. The efforts of many scholars have been concentrated on establishing such criteria. No astronomical synchronization is yet available for events before the 2nd millennium B.C. The estimates of the duration of archaeological periods in this range of time and their absolute chronology depend largely on fragmentary historical information and on archaeological evaluation of the time that it took the various cultures to develop and the debris that represents them to accumulate. Results obtained from the valuable contribution of W. F. Libby and his associates at The University of Chicago, who developed a method for dating organic remains by their content of the radioactive isotope of carbon (C^{14}), seemingly are not greatly at variance with those obtained through archaeological estimates. The number of well-stratified specimens from Mesopotamia tested by this method was still too small in the mid-1950s, however, for decisive conclusions.



COMPARATIVE CHRONOLOGY, NORTH AND SOUTH MESOPOTAMIA. DASHED LINES INDICATE APPROXIMATE DATING

All archaeological material from Mesopotamia can be divided into two major groups. The first represents all the phases of prehistoric cultures; the second contains the products of the distinctive Mesopotamian civilization.

Mesopotamian Civilization.—During the last stage of Mesopotamian prehistory, a number of distinctive regional cultures were submerged by a relatively widespread and homogeneous, if somewhat monotonous, material culture known as the Ubaid. It extended over a large area of western Asia, from the Iranian highlands to the Mediterranean coast in northwest Syria and from the southern borders of Anatolia to the Persian gulf. Sometime during the first half of the 4th millennium B.C. the trend was reversed, the homogeneous material culture being replaced by a number of differentiated cultures in smaller areas. This development in one of these areas—the southern plain of Mesopotamia—is especially noteworthy, for there emerged, apparently for the first time in human history, a civilized society.

Cultural traits that distinguish a civilized society are many and vary in character and degree for different civilizations. One trait that is common to most civilized societies is literacy. The invention of writing in the Protoliterate period is therefore an important landmark in the history of Mesopotamian culture. Moreover, concurrent with the appearance of writing there emerged a number of new traits which remained characteristic of Mesopotamian civilization throughout its history. One of the major tasks of Mesopotamian archaeology consists of the discovery of such distinctive traits, the tracing of their development and changes and their interpretation in terms of cultural history.

Archaeological material from Mesopotamia is often divided into the following classes: architectural remains, art products, written documents, tools and weapons, utensils, personal ornaments, etc. Architecture includes temples, palaces, fortifications, private dwellings and even building materials. Art includes sculp-

ture in the round, bas-reliefs, glyptic, painting, etc. Out of the tremendous mass of material remains might be mentioned some that represent best the distinctive character of Mesopotamian civilization: its writing, its architecture and its glyptic.

The distinctive method of writing is known in its fully developed form as cuneiform. Its development from earlier, pictographic writing can now be traced. It was apparently invented by Sumerian-speaking people, later adopted for a totally different family of Semitic languages and in turn borrowed from them for non-Semitic languages in later times. The architecture, unlike the writing, derived some of its elements from prehistoric periods. Some features are undoubtedly attributable to the building material of Mesopotamia. However, it is not necessary to assume that its main characteristic features were predetermined by this material. Its outstanding feature is the temple, often combined with an artificially raised platform. Mesopotamian architecture, too, was adopted in other periods in other regions.

A distinctive form of glyptic, the cylinder seal, is, as it were, a hallmark of Mesopotamian material culture. This form of art, like the writing, appeared for the first time in the Protoliterate period and had a continuous history of development and change for 3,000 years. Like the writing and the architecture it was adopted by other regions, where it often underwent an independent evolution. Cylinder seals, being small and valuable objects, were often exported from one region to another and thus serve as an important guide for archaeological synchronization. The stylistic development of cylinder seals is one of the main bases for the distinction of the various cultural periods, and iconographic study of their subject matter is an invaluable source for the understanding of Mesopotamian religion.

The picture of ancient Mesopotamian civilization that emerges from the study of the archaeological material, though far from complete, is of interest in many respects. Not only was it the first civilization in human history, with all the freshness and vigour of an original achievement, but the emergence and persistence of its distinctive individual "form" merits close scrutiny. Less isolated and sheltered than Egypt, Mesopotamia was from the beginning a meeting ground for various ethnic and linguistic groups and their cultural tendencies, with all the implied mutual influences and conflicts. At the very beginning of this civilization, at least two distinctive linguistic groups were on the scene as partners in its creation. The writing was apparently invented by the Sumerians, but even in the earliest texts loan words from the Semitic Akkadian have been recognized. The writing itself was eventually taken over by the Semites, whose language—Akkadian—was in turn influenced by its long association with Sumerian. Not only the writing but many other distinctive traits of Mesopotamian civilization appeared as early as the Protoliterate period, survived and developed throughout the Early Dynastic period with its predominantly Sumerian character and continued without a perceptible break after the Sumerians had disappeared. Subsequent political changes, ethnic movements, wars and conquests did not succeed in destroying the distinctive character of this civilization, though the influences of these events are often reflected in the material culture. The full history of this civilization, which preserved its individuality for more than three millenniums through language barriers, ethnic changes and political and economic vicissitudes, is the subject of Mesopotamian archaeology.

C. East Mediterranean Littoral

By the term "east Mediterranean littoral" is meant the areas of Syria and Palestine along the eastern coast of the Mediterranean. Following the first village cultures of the 5th millennium B.C., the Chalcolithic period in Palestine is designated as the Ghassulian from the type site, Teleilat el-Ghassul, in the Jordan valley. Copper smelting was known by this time, though the most astonishing discoveries have been the remains of elaborate, multicoloured paintings on house walls. One which depicts a star is about six feet in height. This, together with a number of grotesque masks and other items, indicates a high degree of imaginative activity. Since its discovery in 1929 this culture has been found widely distributed in Palestinian valleys and plains; discoveries were made by the Israeli department of antiquities in 1954 near Beersheba, where a subterranean village was found tunneled beneath the surface of a field.

In Syria the Chalcolithic period consists of cultural phases in which the contemporary painted pottery of the Halaf and Ubaid periods of northern Mesopotamia is represented by importation and native imitation. No significant architecture comparable with that in Palestine at the time had been discovered by the mid-1950s.

Bronze Age.—During the last two or three centuries of the 4th millennium a new cultural epoch was introduced which is labeled the early Bronze Age. In Syria and Palestine it is known to begin before the first dynasties in Egypt and Babylonia by the artifacts found in early Bronze I (*e.g.*, Protoliterate seal impressions of Mesopotamian origin in both countries and a late predynastic Egyptian slate palette at Jericho), while imported Syro-Palestinian jars and pitchers in tombs of the Egyptian 1st dynasty inaugurate early Bronze II. About the turn of the 3rd millennium B.C. Syria and Palestine shared with Egypt and Mesopotamia in a sudden burst of new cultural energy. Judging from the depth and spread of the deposits, population must have increased greatly and social organization become more complex. Massive city walls were erected at Jericho, Ai, Megiddo, Dothan and elsewhere in Palestine. In fact, Jericho exhibits during the 3rd millennium no fewer than 14 successive city walls or wall components. Temples have been found at Megiddo, Jericho and Ai, while in Syria Byblos by about 2700 B.C. appears to have become a crown colony of Egypt. The importance of this age in the cultural history of Syria-Palestine has only become clear from a number of excavations from about 1935; it is the first period of extensive city-state development and expansion.

In Syria the middle and end of the 3rd millennium are marked by the succession of the Khirbet Kerak and caliciform pottery cultures. In Palestine major disturbances during this time brought an end to the early Bronze civilization, and no city excavated by the mid-1950s showed a continuous occupation between 2500 and 2000 B.C. Only the end of the caliciform period is represented in a brief revival of early Bronze traditions in middle Bronze I (2100–1900 B.C.), at which time Jordan exhibits the first signs of extensive urban installations.

Between 1900 and 1200 B.C. (middle Bronze II to late Bronze II) Syria and Palestine for the first time show a striking unity in material culture. Perhaps the type site in Syria is Ras Shamra on the coast south of Antioch. This city was excavated by a French expedition in successive seasons in 1929 and following years, interrupted only by World War II. There, as at Byblos, Megiddo and Gezer, imported objects of the Egyptian 12th dynasty establish the chronology. The cultural revival about 1900 B.C., illustrated so vividly by the rich tombs of the princes of Byblos, brought with it a fine new pottery, characterized especially by beautiful carinated bowls made from metallic prototypes. During the Hyksos period (*c.* 1700–1550) the introduction of the horse and chariot was accompanied by the construction of large beaten-earth enclosures, the most notable of which have been found at Qatna in Syria and Hazor in Palestine. High ramparts also came into being around many citadels; in Palestine they were typically of cyclopean masonry at the bottom with a brick superstructure. Perhaps the climax in the Syro-Palestinian artistic development came between the 17th and the 14th centuries B.C., as shown

especially by the jewelry, faïence, ivory carving and glyptics.

The most important architectural monuments of the period are the temples and palaces found in the royal cities; that is, in the capitals of the city-states. Most important is the temple of Baal at Ras Shamra, near which the scribal archives were discovered, beginning in 1929. The clay tablets of this library (*c.* 14th century B.C.) were written in a specially developed cuneiform alphabet script, and they were found to contain a portion of the long-lost Canaanite religious literature. The elaborate palace of the same site contained many more documents of a business and diplomatic nature. An earlier palace at Atchana (Alalakh), east of Antioch on the Orontes, was uncovered by a British expedition between 1936 and 1949. It dates from the 18th century and contained numerous tablets which revealed something of the political history of this city in the time of the Mari archives on the middle Euphrates. Even more elaborate was the 15th-century palace at the same site, together with the statue of one of its kings, Idrimi, who had inscribed his autobiography on it.

Iron Age.—During the late 13th and early 12th centuries the Bronze Age culture of Syria and Palestine was brought to an end by successive waves of invaders, especially Israelites, Aramaeans and "peoples of the sea."

In Syria insufficient excavation has been done in the Iron Age which followed these events to enable us to gain a clear picture of the cultural sequence. The excavations of the Oriental institute of The University of Chicago at Chatal Huyuk and Tell Judeidah in the Amuq plain (1933–36), and Sir Leonard Woolley's work at El-Mina (1936–49), promised much in filling the gaps in our knowledge. The latter site was an important port at the mouth of the Orontes river for the Aegean trade between the 8th and 4th centuries B.C. At Chatal Huyuk a fine palace with adjoining temple of about the 8th century was unearthed. The temple is particularly interesting because it is the only Iron Age temple excavated in Syria by the mid-1950s; its plan is similar to that of the Solomonic temple in Jerusalem.

In Palestine, knowledge of the Iron Age is much more detailed. The type sites are Tell Beit Mirsim, excavated by the American Schools of Oriental Research and the Pittsburgh-Xenia Theological seminary (1926–32), and Megiddo, excavated by the Oriental institute (1925–39). During the 12th and 11th centuries B.C., iron was introduced by the Philistines for weapons and jewelry. Thereafter it came into common use for agricultural tools as well. The greatest density of population and cultural vigour appeared between the 10th and 8th centuries B.C., from which time excellent architecture, the work of Israelite kings, has been recovered at Megiddo and Samaria. The economic and cultural centre was then in the hill country, and the changes in ceramic styles were so gradual that a fairly stable life until the third quarter of the 8th century B.C. was presumed. Then the country became a province of Assyria, after which rapid decline and violent destruction occurred. The devastation of Judah by the Babylonians in 587 B.C. was so severe that town after town was abandoned. Two centuries at least passed before full recovery was made.

During the Persian period of the late 6th through the 4th centuries, the ceramic culture is in general a continuation of that of the preceding period, but three things among others are particularly notable: (1) The first coins appear in the 5th century; these were the Persian empire's adaptation of Greek coinage. (2) Beautiful silver vessels indicate the new industry created by Phoenicians after the decline of their ivory carving. (3) Syria and Palestine were being flooded with pottery from Greece. By the 4th century, for example, the Greek style of lamp had replaced the native type which had been in use for over 1.000 years. Greek influence on the material culture, at least, was thus much earlier than the conquest of Alexander the Great.

D. ANATOLIA

Anatolia, the peninsula called Asia Minor and the region east of it, all in present Turkey, was in the 2nd millennium B.C. the main part of the Hittite empire. Information about the history and civilization of the Hittites comes from the archives of their capital, Hattusa, modern Boghaz Keui, about 100 mi. E. of Ankara. The site has been known since 1834 (Charles Texier); the archives were excavated in 1906–12 and again in 1931 and after. Only the central plateau of Anatolia was really settled by Hittites, a people whose language belongs to the Indo-European group, whereas outlying territories were linked to the empire as vassal kingdoms. Also archaeologically, Anatolia is divided into zones which show different cultures from the earliest times on. Type sites for the central area are Boghaz Keui, Alisar Huyuk near Alaca, and Kultepe. After the Chalcolithic Age (4th millennium), with a village culture characterized by mud-brick houses and handmade pottery, an accumulation of wealth, probably indicating concentration of political power, appears in the tombs of Huyuk toward the end of the early Bronze Age (end of 3rd millennium). The introduction of the potter's wheel, around 2000, marks a new type of pottery which remains in use, though with changes, throughout the middle and late Bronze Ages (2000–1200), corresponding to the historical periods of the Assyrian merchant colonies (20th–19th centuries) when the first Hittites are attested by proper names, the old (*c.* 1700–1400) and new Hittite kingdoms (1400–1200); it is therefore called Hittite pottery.

The type site in the northwest is Troy, whose Level I corresponds roughly to the central Chalcolithic, whereas Troy II with its famous treasure is similar to the early Bronze Age tombs of Huyuk. In shape and technique, however, the material culture of Troy is different from that of the central plateau. The finds of Troy III–VII and British excavations at Beycesultan in Caria (1954) show that the west used a pottery different from that of the Hittites even at the time of the Hittite empire when part of this region, the Arzawa countries, were Hittite vassals.

South of the Taurus range, in Cilicia and north Syria, a separate material culture was found at Mersin, Tarsus, Sakchagozu, mounds in the plain of Antioch, Carchemish on the Euphrates, etc. Artifacts in this region go back to the Neolithic Age. In the Chalcolithic Age, pottery of the Halaf type links it to north Mesopotamia (Tell Halaf on the source of the Habur river). The potter's wheel was introduced there much earlier than on the plateau, and Hittite types remain sporadic even during the new kingdom when this region belonged to the Hittite empire.

The northeastern highlands of Turkey are still little explored; early Bronze Age finds at Tilkitepe near Van and Karaz near Erzerum remain isolated, although the latter seem to form a link with the Caucasus region. After the downfall of the Hittite empire (*c.* 1200) the western part of the plateau became the Phrygian kingdom. Around Lake Van the kingdom of Urartu produced rock architecture and refined bronze objects. Small Hittite states lived on in the region from Kayseri (Caesarea Mazaca) southward into north Syria. The establishment of Greek colonies along the coasts hardly affected the culture of the interior.

What is generally known as Hittite art must be divided into the Anatolian art of the Hittite empire and the late Hittite art of the southeast. Monuments of both are often inscribed in Hittite hieroglyphs, a system of writing developed in Anatolia in the 2nd millennium and used to write a language different from Hittite but also of Indo-European stock and closely related to Luwian, another language attested in the Hittite archives. Imperial Hittite monuments centre around Boghaz Keui and in the Taurus range, with outlying examples in the south (Cilicia, north Syria) and west (near Smyrna and Konya); they are rock carvings and stone reliefs. Of stone monuments older than the empire only a few fragments survive (Boghaz Keui, Kultepe); the main source for preimperial Anatolian art are the numerous seals (mostly stamps, rarely cylinders) and seal impressions. The subjects of monuments and small art objects alike are religious, representations of gods and worship. The stone monuments are architectural, carved slabs adorning gates and temples. The creation of long series of relief orthostates is characteristic of this

art (Huyuk). The late Hittite states of the southeast carry on this tradition of religious architectural sculpture; main find spots are Malatya, Carchemish, Marash, Zinjirli, Sakchagozu and Karatepe. Some of the motifs and stylistic elements of this late Hittite art are believed to have influenced the "orientalizing" style of Greece. The Phrygian rock monuments, found between Afyon Karahisar and Eski-Shehr (Eskisehir), show, in turn, the impact of early Greek art on the Anatolian plateau around 700 B.C.

V. NEOLITHIC AND BRONZE AGES IN EUROPE

A. Neolithic Age

Origins of European Neolithic.—Europe received from southwestern Asia the material bases of the Neolithic economy—cultivated wheats (*Triticum monococcum*, *T. dicoccum* and *T. spelta*) and barleys and, among domestic stock, probably sheep—together presumably with the techniques of husbandry. But in Europe Neolithic farming was developed on novel and original lines imposed by environments that differed radically from those of the cradle of farming in the near east.

Europe falls into four distinct ecological zones: the Mediterranean zone of evergreen forest and winter rains; north of the Pyrenees, the Alps and the Balkans, the temperate zone of deciduous forest and evenly distributed annual rainfall; still farther north the circumpolar taiga or coniferous forest; and to the southeast the western end of the Eurasiatic steppes. Each zone itself is subdivided into natural regions by physiographic boundaries and peculiarities of climate or soil. Only the three major divisions of the temperate zone are not obvious from every map. We may distinguish: western Europe, from the Atlantic to the Vosges and Alps and including the British Isles; the loesslands of central Europe, including the Ukraine and limited by the Balkans and the Harz; and the northern province, that portion of the Eurasiatic plain lying between the Rhine and the Vistula and including Denmark and southern Sweden.

While the cereals and sheep were presumably introduced by an actual infiltration or immigration of Neolithic peasants from Asia, the substantial Neolithic communities that arose by 3000 B.C. must have been largely recruited from indigenous Mesolithic hunters and fishers, attested so abundantly in western and northern Europe by the remains described in section III above. (Some communities indeed seem to be composed entirely of such Mesolithic stocks, though they had adopted a Neolithic equipment from immigrant farmers; such are termed "Secondary Neolithic" by British prehistorians.) From these Mesolithic survivors too must be derived much of the science and equipment applied in Neolithic times to adapting societies to European environments, though here again contributions from the orient may be admitted. Upon the resultant distinctively European technology and economy was reared a no less original ideological superstructure expressed in distinctive sepulchral monuments, styles of ceramic decoration and fashions in personal ornaments.

Rural Economy.—In each of the above-mentioned provinces the archaeological record opens with fully developed and individualized Neolithic cultures, divergently adapted to the peculiarities of their several environments. The period of immigration and formation had already passed—unnoticed—in the Mesolithic Age. Still some common features justify the adjective "Neolithic."

Save in the taiga, where a Mesolithic economy persisted until the end of the Bronze Age, the basis of life everywhere was subsistence farming supplemented by some measure of hunting and fishing—fish being a source of food curiously neglected in western and central Europe during the earlier phases of the Neolithic. Everywhere the same cereals were cultivated together with beans, peas and lentils. In the Mediterranean zone orchard husbandry may already have begun, while round the Alps apples were eventually cultivated and utilized for the preparation of a sort of cider. The balance between cultivation and stock breeding varied. Throughout the temperate zone sheep, though bred even in Britain and Denmark, were at first rare. The damp temperate forests were uncongenial to these animals, and only toward the end of the Neolithic Age, when the greater dryness of the subboreal climatic phase and incipient clearing for plow cultivation were leaving their mark on the landscape, did flocks begin to multiply. On the loesslands in early Neolithic times animal husbandry may have played a subordinate role as compared with agriculture. But in the sequel, cattle raising combined with hunting proved to be the most productive pursuit among the deciduous forests with a Neolithic equipment; cultivation was relegated to an increasingly secondary place until in the late Bronze Age more efficient tools for clearing land became generally available. The rural economy permitted the continuous occupation of permanent villages round the Aegean and in the Balkan peninsula, perhaps also in south Italy and the Iberian peninsula. In the temperate zone, however, shifting cultivation based on slash-and-burn clearance was the rule and involved the periodical removal of the complete village. Under this extravagant system plots were presumably tilled with hoes, as in parts of Africa today. But by the beginning of the Bronze Age the ox-drawn plow was beginning to replace the hoe.

Houses.—Dwelling houses in Greece, Sicily and the Iberian peninsula were built, as in the near east, of pisé or mud brick on stone foundations. But in the Balkans and throughout the temperate zone, wood was used for the construction of gabled houses, stout posts serving to support the ridgepole and the walls of split saplings or wattle and daub. The earliest houses on the loessland of central Europe were very large, up to 42 m. (135 ft.) in length and large enough to accommodate a whole lineage or small clan together with stalled cattle and grain stores. In the sequel these communal houses gave place to smaller two-roomed dwellings, 7.5 to 10 m. (24½ to 33 ft.) long, but still entered through one end. Finally in late Neolithic times clusters of one-roomed huts became the most widespread fashion. Round the Alps such two-roomed houses and, less often, one-roomed huts were raised on piles above the shores of lakes or on platforms laid on peat mosses. These are the world-famous Swiss lake dwellings that have yielded such precious collections of the organic substances from wood to bread that are otherwise missing from the archaeological record. In northern Europe too the earliest villages consisted of two parallel long communal houses, but these were subdivided by cross walls into 20 or more apartments, each with a separate door. But here again the communal houses eventually broke up into free-standing one-roomed huts. Finally Skara Brae (*q.v.*) on the treeless island of Orkney illustrates an ingenious adaptation of the one-roomed wooden hut to an inhospitable environment, but shows how commodiously such huts must always have been furnished.

Stone Tools.—Carpenters used celts (ax or adz heads) edged by grinding and polishing of fine-grained rock or of flint where that material was available in large nodules. In Greece and the Balkans, all over central Europe and the Ukraine and throughout the taiga, adzes were used exclusively as in the earlier Baltic Mesolithic; in northern and western Europe axes were preferred. In the Iberian peninsula axes and adzes occur in equal numbers in early Neolithic graves, but the proportion of axes increased later. Often in western Europe and occasionally in Greece and Cyprus celts were mounted with the aid of antler sleeves inserted between the stone head and the wooden handle—a device already employed in the north European Mesolithic. In Spain, the British Isles and northern Europe axheads were simply stuck into or through straight wooden shafts, but adz heads must always have been mounted on a knee shaft (a crooked stick), a method regularly used for axheads too by the Bronze Age. Axheads like those in modern use, with a hole for the shaft, were rarely used for tools, but the Danubian peasants on the loesslands may sometimes have mounted adzes in this manner. They certainly knew how to perforate stone, using a tubular borer (a reed or bone with sand as an abrasive). From them the technique was adopted by various secondary Neolithic tribes in northern Europe for the manufacture

of so-called battle-axes. The latter seem to derive their form from Mesolithic weapons of antler, but their splayed blades disclose the influence of metal forms.

Ax Factories and Flint Mines.—Celts were manufactured in factories where specially suitable rock outcrops occurred and were traded over great distances. Products of the factories at Graig Lwyd, Penmaenmawr, north Wales, were transported to Wiltshire and Anglesey, those of Tievebulliagh on the Antrim coast to Limerick, Kent, Aberdeenshire and the Hebrides. Similarly, large nodules of good flint were secured by mining in Poland, Denmark, the Netherlands, England, Belgium, France, Portugal and Sicily. The mine shafts, cut through solid chalk sometimes to a depth of 20 ft. with the aid only of antler picks and bone shovels, may be simple pits, but often regular galleries branching from them follow the seams of big nodules. Though the ancient miners appreciated the necessity of leaving pillars to support the roof, skeletons of workers killed by falls have been discovered at Cissbury, Spiennes and elsewhere. In the British Isles and Denmark at least there is evidence that the ax factories and flint mines were exploited, and the products distributed, by men of Secondary Neolithic stocks. Still the operators and distributors need nowhere be regarded as full-time specialists.

Weapons.—The sling and the bow and arrow were of course employed in Neolithic times. The sling was used apparently to the exclusion of the bow in Greece, the Balkans and central Europe; arrowheads were common from the start in the Iberian peninsula, western and northern Europe and the taiga but appeared in central Europe only in late Neolithic times, in Greece first in the Bronze Age. These missiles might be huntsmen's tools as well as weapons of war. Indeed there is little evidence for war in early Neolithic Europe save in the northern province and the Iberian peninsula. By late Neolithic times, on the contrary, settlements are often fortified everywhere and martial weapons are prominent. The most unmistakable of the latter are the battle-axes described above. They are distinctive of a series of pastoral tribes—"Battle-Ax folk"—who emerged in late Neolithic times in central Russia, round the Baltic, in the Saale-Elbe valleys and round the Alps.

Burial Rites and Megalithic Tombs.—Neolithic farmers were generally buried in a flexed or contracted position on the side, except in northern Europe, where the corpse lay extended on its back, as was the custom also among the surviving hunter-fishers of the taiga and Russia. In Britain Secondary Neolithic folk practised cremation, burying the ashes in circular enclosures, one of which was destined in the Bronze Age to become the world-famous sanctuary of Stonehenge (*q.v.*). But the most celebrated and imposing funerary monuments of the European Neolithic are collective tombs or family vaults, some built of huge undressed stones and so rightly called megalithic, others walled with dry stone masonry and roofed by corbeling, others simply cut in the rock. Save for a cluster on the northern slopes of the Caucasus, such tombs are virtually confined to the Mediterranean coasts, the Iberian peninsula and western and northern Europe and are most densely concentrated near the coasts. The simplest, but not necessarily the oldest, type of megalithic tomb, the true dolmen, is confined to northern Europe and was originally designed to contain a single extended skeleton. Passage graves, consisting of a polygonal chamber entered by a distinct passage and covered with a round tumulus, probably originated in Portugal and spread thence by seaways to Brittany, Britain and Denmark. A corbeled version of the same plan, termed a tholos, perhaps started in southeast Spain and was thence diffused on the one hand as far as Orkney and on the other to Greece. Finally, gallery graves—long, narrow chambers with no distinct entrance passage, often covered by a long cairn with a crescentic forecourt at one end—are distributed from the Gulf of Lyons across France to Scotland and northern Ireland. A special variant, generally subterranean, was developed in the Seine-Oise-Marne basin and carried with a distinctive assemblage of pots, weapons and personal ornaments by migrating bands to the Channel Islands and across Belgium and Westphalia to southern Sweden.

Art.—Neolithic art, save among the hunter-fishers of the taiga, was geometric and not representational. It is best illustrated by the decoration of pottery. Pots, always handmade, were painted in southeastern Europe, south Italy and Sicily; elsewhere they were adorned with incised, impressed or stamped patterns. Many designs are skeuomorphic, *i.e.*, enhance the pot's similarity to vessels of basketry, skin or other material. But on the loesslands of central Europe and the Ukraine and in the Balkans spirals and meanders were favourite motifs.

Trade.—While Neolithic societies could be completely self-sufficing, growing their own food and making all essential equipment from local materials, luxury objects were transmitted quite long distances by some sort of trade. So ornaments made of the shells of the Mediterranean mussel, *Spondylus gaederopi*, are found all across the Balkans, up the Danube valley and even on the Saale and the Main. Products of factories and flint mines were, as stated, traded widely throughout a single province, such as the British Isles, and some specially valued raw materials—the yellow flint of Grande Pressigny (France), the obsidian of Melos and the Lipari Islands—became objects of "international trade" as much as shells. But the most prized object of such commerce was the amber of Jutland and East Prussia, whose electrical properties seemed evidence of potent mana. Eventually the amber trade, extended to Greece, provided the distributive machinery that made a Bronze Age possible in central Europe.

B. Bronze Age

Origins of Metallurgy in Europe.—The term Bronze Age is misleading, since in many parts of Europe, as in Egypt and the near east, most of the metal objects used to define the "age" were made of copper unalloyed with tin, but the usage is too well established to be changed here. It now seems highly probable that native copper was discovered in Hungary, methods of working it cold and perhaps even by fusion were independently devised there, and the curious implement termed an ax-adz was invented by local artisans. An equally independent centre of metallurgy in the Iberian peninsula is likewise possible though less likely. Still, in general, the knowledge of copper smelting and of alloying copper with tin was almost certainly brought to Europe from southwestern Asia.

Aegean Bronze Age.—In Greece and Crete the Bronze Age seems to have been initiated soon after 3000 B.C. by immigrants from Asia Minor who founded little townships on the coasts and islands, introduced the plow as well as metallurgical techniques and developed maritime trade with the near east, Egypt and perhaps also with south Italy and Sicily. Soon after 2000 B.C. in Crete Early Aegean culture developed, through the concentration of wealth and power in the hands of princes or priest-kings, into a genuine civilization, known as Minoan. The princes built themselves palaces, the potter's wheel was introduced and a system of writing was devised. About the same time the Early Helladic townships of mainland Greece were sacked by warlike invaders, probably speaking Greek, but were immediately rebuilt as Middle Helladic townships. Among these, Mycenae (*q.v.*) rose to a position of hegemony about 1600 B.C. Its kings, who were buried in the six shaft graves excavated by Heinrich Schliemann and in another group of nine discovered in 1951, attracted to their courts Minoan-trained armourers and artist craftsmen from Crete; they also imported amber from Jutland. Then between 1550 and 1500 B.C. there was a change of dynasty and of burial rites at Mycenae. Tholos tombs replaced shaft graves as royal sepulchres. The erection of similar tholos tombs at many other cities in Greece must indicate the rise in them too of local kings. By 1400 B.C., if not before, Crete too was conquered by mainland Greeks and became a province of Mycenaean culture.

Bronze Age I in Spain and Portugal.—In the Iberian peninsula too it is likely that intelligent metallurgy was introduced by colonists from the east Mediterranean. In any case settlements such as Los Millares in Almería, Alcalá in southern Portugal and Palmella near the Tagus estuary are remarkably like the Early Helladic townships of Greece. But there, though copper from local ores was used for weapons (daggers) and craftsmen's tools (adzes and saws), it was not alloyed with tin and did not, as it had in

Greece, oust stone even for weapons. Indeed flintworking now reached its highest peak of excellence. The corbeled and megalithic passage graves were still used as family vaults; the finest were actually first built in this period, termed Bronze I. Only in the succeeding Bronze II, when Los Millares had been replaced by El Argar, did single graves among the houses take the place of collective tombs and was copper alloyed with tin from Galicia and north Portugal.

Early Bronze Age in the Temperate Zone.—In the temperate zone, apart from Hungary, the Bronze Age begins with the arrival of a warlike brachycephalic stock, termed by archaeologists the Beaker folk because of the very distinctive vase regularly buried in their graves. The Beaker folk were primarily bowmen but were armed also with a flat, tanged dagger or spearhead of copper (not bronze) and wore ornaments of gold, copper, amber, jet or callaïs. They may have begun the exploitation of local ores and the organization of the distribution of metal. But in central Europe the systematic production and distribution of bronze was initiated by metallurgists from north Syria who have been termed Torque Bearers from a distinctive sort of neck ring with recoiled ends that was worn by their patron deity in north Syria (as shown by a small idol found there) and that in Europe served as an ingot and perhaps as currency. By 1600 B.C. copper from the Austrian Alps and Slovakia, alloyed with tin from Bohemia and Saxony, was being distributed in connection with the trade in amber. This fossil resin was being conveyed from Jutland up the Elbe, across the Brenner pass and down the Adriatic to Mycenaean Greece and Crete. Commerce along this transcontinental route was linked up in southern England with an ill-defined "long-sea" route that by 1450 B.C. at latest was conveying to the Aegean markets Cornish tin, Irish gold and even crescentic amber necklaces and other articles made in England. "International trade" along these routes supplied raw materials to local bronzesmiths who manufactured diverse types of weapons and ornaments to suit the divergent tastes of local purchasers in north Italy, Hungary, Austria, Bavaria, Czechoslovakia, Saxo-Thuringia, Silesia and the British Isles. No local smiths yet worked for the north European market, and the rest of the temperate zone as well as the taiga remained virtually Neolithic.

In the foregoing regions (and by Bronze II in Spain), despite local divergences, certain common types of tools and weapons—flat, triangular knife-daggers, halberds, flat or flanged axes—were current for some time. Since they were later replaced by more efficient types, the period of their currency is termed the early Bronze Age. Then the consumers of bronzeware in central Europe were peasant farmers settled in the fertile, loess-clad valleys, the intervening uplands and heaths being grazed by pastoral tribes, still almost without metal gear. In the British Isles, on the contrary, it was the more pastoral groups, the builders of round barrows, who used bronze weapons. The graziers of the Wiltshire downs were the most prosperous and soon grew so rich and numerous that they could erect the gigantic sanctuary of Avebury and the still more celebrated lintel circles at Stonehenge. Their Irish counterparts' kings were buried in the sculptured tholos tombs of the Boyne. Characteristic ornaments of the British early Bronze Age—crescentic necklaces formed of strings of jet or amber beads and gold collars of similar pattern—were exported to the continent and even to Greece. Finally on the south Russian steppes other pastoral tribes developed an independent Bronze Age province inspired from Transcaucasian centres of metallurgy. The south Russian "Bronze Age"—actually unalloyed copper alone was used—is known only from barrows (kurgans) covering skeletons thickly strewn with red ochre. Save round the Caucasus, these graves are poor in metal gear, but one contained the oldest wheeled vehicle yet known from Europe.

Middle Bronze Age.—Toward 1500 B.C. in central Europe the previously Neolithic pastoralists of the uplands, expanding at the expense of lowland farmers, became the chief purchasers of metal arms. At the same time in northern Europe local smiths began to manufacture ornate bronze weapons and toilet articles to meet the tastes of big ranchers whose burial mounds, covering rich interments in oak tree coffins, still line every ridge in Denmark. Now the flat and flanged celts of the early Bronze Age grew into winged axes and palstaves, while ogival daggers, rapiers and two-edged swords replaced flat, triangular knife-daggers. These innovations serve to define what is termed the middle Bronze Age in central and northern Europe, in Italy and also in the British Isles, but in the rest of western Europe and in south Russia these characteristic types are missing. That does not of course mean a depopulation of either province.

Late Bronze Age.—During the late Bronze Age socketed celts replaced palstaves, winged axes and even shaft-hole axes, while warriors came to prefer slashing to thrusting so that sword blades tended to become leaf-shaped. Though both new types were eventually adopted throughout western Europe and in the Iberian peninsula, and socketed celts even in eastern Russia too, their adoption was far from simultaneous everywhere. The late Bronze could also and more significantly be defined by a great increase in the use of metal, which was now employed freely even in agriculture and for rough work. Such use means that bronze must have become much cheaper than ever before. One cause for this was certainly a considerable extension of mining. In the Austrian Alps survive old mine shafts with timbered galleries still containing bronze gads and other tools employed by the miners, who knew how to break up the rock by the method of fire setting. At the same time the distribution of metal and metalware was reorganized and extended into new fields. Large objects such as bronze shields, helmets, buckets and cups were exported, for instance, from the Carpathian basin to Italy, the Ukraine, Norway and England or from Ireland to Denmark, Brittany and Spain. Cheap metal tools and above all the socketed ax, the first really cheap and efficient implement for tree felling, allowed an immense expansion of plow cultivation and also of sheep breeding, a proportionate increase in the food supply and consequent growth in population.

Urn Fields.—This growth is attested by the number and size of the flourishing villages and still more of the cremation cemeteries, termed urn fields. For a feature of the late Bronze Age was the general adoption of cremation with inurnment of the ashes, first in central Europe and north Italy, but spreading to the Ukraine, to Sicily, to Scandinavia and across France to the Iberian peninsula, in some cases at least as a result of folk movements. The late Bronze Age certainly witnessed an intensification of warlike behaviour. Settlements were normally fortified, often by quite monumental works. The enlarged supplies of bronze were largely devoted to armaments. Besides many offensive weapons, helmets, shields and even cuirasses were made of beaten bronze. At the same time the horse-drawn chariot began to play in European warfare the part that it had in the near east since 1700 B.C.

End of the Mycenaean Age.—The foregoing events in temperate Europe and the western Mediterranean partly coincide with a Dark Age in the eastern Mediterranean and are not unconnected therewith. Between 1225 and 1150 B.C. the near east was ravaged by barbarian invaders, some of whom may have come from Europe. As a result the Mycenaean Greeks were cut off from the markets and supplies of Asia. Perhaps they sought compensation for the loss of Asiatic supplies of metal in central Europe and thus initiated the mining activity described above. But about 1100 B.C. the Mycenaean civilization itself collapsed as a result of complex disturbances traditionally termed the Dorian invasion. With the consequent loss of the Mycenaean market, the miners and smiths of temperate Europe had to produce for local consumption. Though in the near east and Greece the Bronze Age had ended by 1100 B.C., it certainly lasted much longer in the temperate zone and in the western Mediterranean. How long is hard to say, because of the drying up of written records in the Dark Age, but at least till 700 B.C. in central Europe, till 400 B.C. in England and much longer still in Scotland and Ireland. So too in Russia, while the socketed celt was adopted round the Urals about 1300 B.C. it was not replaced by iron tools till 700 or even 500 B.C.

VI. CLASSICAL ARCHAEOLOGY

Classical archaeology is concerned with the study and interpretation of the material remains of the civilizations of Greece and Rome. Thus, its area is coextensive in time and space with these civilizations: from their beginnings in the early Iron Age (9th and 8th centuries B.C.), when the city-states were developing their typical institutions, to the gradual transformation into the medieval world of western Europe and Byzantium in the 4th century A.D. Greek civilization, however, shared the heritage of the Bronze Age in the Aegean, of the Minoan-Mycenaean culture, so that the problem of filiation is also of importance. While classical archaeology is primarily concerned with the centres of Greece and Italy, its study is necessary in understanding the expansion and influence of Greek and Roman culture throughout the Mediterranean area, from Spain and Great Britain to south Russia and the near east and from the Sahara to the Baltic. With the better-known remains of Greece and Italy as a guide, an important phase of the history of all those regions which participated in the western tradition of civilization through the colonial activity of Greece and the imperial expansion of Rome may be illuminated.

Branches of Study.—It is obvious that the quantity and complexity of the remains of more than 1,000 years of human activity in the Mediterranean area have necessarily led to a great degree of specialization in the study. The mature civilization of Greece and Rome was a highly developed, wealthy, urban culture, so that its most obvious remains are those of the thousands of cities and towns which came into existence during its history. The names of many of them, like those of Athens and Rome, have remained firmly attached to their proper locality by continuous inhabitation. Many, however, have to be identified; the siting and physical growth of each is significant for its history. Thus, topography is a primary branch of archaeological study. In the Mediterranean area the builders of these cities usually found good supplies of building stone at hand, so that the important structures of the cities were built of limestone and marble and. in the case of Rome, of brick and mortar. From the mere accident of durable materials, architecture is an important branch of classical archaeology; it is concerned not only with the formal development of the various styles employed (Doric, Ionic, Corinthian and their variants) but also with the types of buildings developed to satisfy the needs of a complex society: temples, houses, theatres, porticoes, great bathing establishments, meeting places, fortifications. The buildings were decorated with sculpture in stone and bronze (occasionally of ivory, gold and silver), while in the houses, shrines and graves terra-cotta figurines or statuettes of bronze were appropriate; free-standing statues of marble and bronze embellished both public and private buildings. Thus, sculpture forms another branch of study. Local and central governments recorded their decrees and regulations on stone and bronze tablets, while private individuals and groups inscribed their dedications to the gods, epitaphs, etc. The study of these documents is the function of epigraphy. From every excavated city come the ubiquitous remains of pottery vessels and small objects which were used in the household for the storage of food and drink or were dedicated in the shrines and graves. The study of these ceramic remains not only constitutes a special branch of classical archaeology but also offers a chronological guide to the excavator and, in many cases, a clue to the trading connections of the region in which they are found. A somewhat similar role is played by the coins, the object of study of the numismatist. They afford information for political and economic history from their legends and from the quality and kind of metals employed in their manufacture. Painting, too, constitutes an important branch of study; for Greece its history is traced mainly from the vase decoration, but for Rome there are the frescoes on the walls of houses, as at Pompeii, and on tombs. These various branches of study, topography, architecture, sculpture, ceramics, numismatics and painting, are not only special fields in themselves, but the particular material of one period or area may constitute a special field of study from its very complexity.

The material of these special branches of study is arranged in major chronological divisions which reflect the historical development of Greek and Roman civilization: the "Dark Ages" (*c.* 1100–750 B.C.) in which growth started again following the dormant period resulting from the collapse of the Mycenaean culture; the Archaic period, a vigorous and rapid development from *c.* 750 B.C. to the Persian Wars (early 5th century B.C.), which owed much to the renewal of contacts with the near east; the Classical period, in which the Greek city-states attained to maturity, in the 5th and 4th centuries B.C.; the Hellenistic period, when Greek culture was spread in the near east by the successors of Alexander and was eagerly adopted by the growing power of Rome (323–27 B.C.). Roman development is usually divided into two periods: that of the republic (*c.* 509–27 B.C.) and that of the empire, which represents the fusion of Greco-Roman culture.

Role of Classical Archaeology.—In its task of interpretation classical archaeology has an ancillary role for certain of these periods, for others a primary one. It supplements and illuminates the literature and history of the great creative periods of Greece and Rome, from the 5th century B.C. to the 2nd century A.D. The paintings on a Greek vase, for example, may illustrate a festival mentioned in the literature. In this it has somewhat the value of a lively commentary. For these same periods, however, important works of art, such as the Parthenon of Athens or the Column of Trajan in Rome, made comprehensible by archaeology, can illuminate the age as directly as a play of Sophocles or the *Aeneid* of Virgil. The minor objects of a region —the pottery, lamps and coins—may reveal in their totality an economic trend or a social habit not mentioned in the literary tradition. At times, however, classical archaeology goes beyond this ancillary role to provide almost the only key. For example, in Greece the Dark Age period is given a chronology and a material background, however uncertain, through archaeological discoveries. Much the same is true for understanding the effect of Greek and Roman cultural influences on "native" areas as in southern Russia, France or Spain. Thus, we can see the relationship of Greek and Scythian art and can realize that Italian traders were busy in the Alpine districts before Julius Caesar found it expedient to subdue the Helvetians. Classical archaeology, then, is many things to many persons: to the excavators and specialists, first of all an exercise in classification by which its material may be made available and comprehensible to the students of literature, history and religion; to them and to the nonprofessional an activity which can provide objects for aesthetic pleasure and afford a fuller understanding of the civilization which created them.

Throughout its history these two main objectives have characterized classical archaeology: the acquisition of art objects for their own sake and their use for the better understanding of classical culture. In antiquity itself these are casually recognized. Thucydides, in his account of the early development of Greece, states that Carians once inhabited most of the Aegean islands, pointing to the type of armour and burial found in the graves on Delos when the Athenians purified the island in 426 B.C. One could ask little more, except for a catalogue and photographs of the contents of the graves, from a modern archaeologist. Strabo recounts that at the refounding of Corinth by Caesar in 44 B.C. the new settlers happened upon tombs of the old city, destroyed in 146 B.C. They promptly went into the antique business and "filled" Rome with the pottery and bronzes from the graves. Thucydides' attitude, however, was the exception, and, generally speaking, it was this desire for precious objects which characterized excavation from the time of the Renaissance until well into the 19th century. The objects so obtained found their way into private collections and eventually into the museums of western Europe and America. Their importance for the study of art is great, but the information which they might have afforded by proper excavation is irrecoverably lost. Before the early 19th century only sporadic instances of scientific treatment of the remains of antiquity can be pointed out. At that time several factors contributed to the practice of classical archaeology as a means to knowledge, with a proper technique of excavation, rather than as a treasure hunt without rules

or control. The intellectual impetus was given by the application of a more scientific method, as by G. B. Vico and B. G. Niebuhr, to the study of human history; the opportunity was afforded by the improvement of conditions of travel in the Mediterranean countries and, in Greece, in particular, by liberation from Turkish rule. An additional factor, both there and in Italy, has been the growth of national consciousness. This was naturally accompanied by pride in the past and a desire to seek out and safeguard its monuments.

A. Excavation in Greece

Early Period.—While excavation was organized in Greece only after its liberation (1828), much useful information about monuments was recorded and the basis of its classical topography worked out by travelers from the time of the early Renaissance onward. The awakening curiosity of that period was exemplified by Cyriacus of Ancona (1391–*c.* 1457), a merchant, who traversed southern Italy, Illyria and Greece copying inscriptions and making drawings of monuments. Other travelers followed his lead, but the most important work of this type was not done until the 17th and 18th centuries. In 1675–76 Jacques (Jacob or James) Spon and George Wheler traveled through parts of Greece and Asia Minor describing and drawing what they saw in the main centres; before 1687 drawings were made of the sculpture in the pediments of the Parthenon by a French draftsman in the ambassador's suite (the Carrey drawings). Their importance lies in the fact that they record the condition of the pediments before these were largely destroyed by an explosion during the siege of Athens by the Venetians in 1686–87. Other monuments of Athens were more fully delineated by James Stuart and Nicholas Revett, whose fine drawings were published in a series of four volumes between 1762 and 1814, while a similar service was performed for some of the Greek and Roman cities of Asia Minor by Richard Chandler, whose *Ionian Antiquities* was published in 1769. The sponsor of these activities was the Society of Dilettanti in London, whose interest thus made original Greek monuments known in western Europe despite the inaccessibility of Greece to travelers. Their interest was a connoisseurship of the antique, but their service to archaeology was very real in that the details of many structures subsequently destroyed were preserved. Another service of equal value was in the field of topography in the late 18th and early 19th centuries. Here the name of William Leake, whose *Travels in the Morea* (1830) and *Travels in Northern Greece* (1835) are still of value for their accurate observation and judicious resolution of problems, is to be singled out. They have the additional merit of being a very vivid and readable account of the condition of Greece in the last years of the Turkish regime. In its totality the work of Leake and other travelers, mainly British, laid the basis for the more detailed reporting and excavation which were to follow. During this same period the publication of J. J. Winckelmann's *History of Ancient Art* (1764) and of the private collections of antiquities in western Europe offered a chronological framework soon to be modified and enlarged by the results of excavation. In Greece the government established after its liberation proceeded to organize archaeological work, the first regulation of this kind.

One of the first acts of the new regime was the removal of Turkish structures from the ancient buildings on the Acropolis of Athens (1832–36) under the direction of Ludwig Ross, the Bavarian scholar, who acted in the capacity of conservator of antiquities to the government. In 1837 the Greek Archaeological society was founded and, since that time, excavation has been under the general supervision and licence of Greek authorities, with strict control of the export of antiquities. The liberation and early growth of Greece, however, were aided by foreign powers, and from the outset archaeological activity has been generously shared. Foreign schools were encouraged to establish themselves in Athens. These have become centres of study for students and archaeologists from the respective countries, and a large part of the excavation in Greece has been carried out under their auspices and at their expense. Some, such as the French, are supported by their governments, others, such as the American, by private endowment. The oldest of the foreign schools is the French, founded in 1846; the German institute was organized in 1874; the American School of Classical Studies began operations in 1882, the British school in 1885. Other such institutions were the Austrian, Italian and finally the Swedish school in 1948. Thus, from the outset, the practice of archaeology has been an international activity, reflecting the interest of western Europe and America in its own cultural tradition and disseminating the results in the publications of the various schools as well as those of Greece itself.

A consequence of the foundation of the foreign schools and of the growth of Greece was the inception of large-scale excavation on the major sites. It was wholly natural, of course, that religious centres and important cities should be the objects of attention, but unfortunate that they formed the necessary training ground for the development of excavational techniques. The uncovering of large buildings and the discovery of important groups of sculpture such as that of the Temple of Zeus at Olympia and the Acropolis "Maidens" naturally held the focus of interest; the realization that the careful recording of pottery and minor objects for the stratification and history of a site was necessary grew slowly; it was rarely demonstrated until after 1900, as in Sir Arthur Evans' excavation of Knossos and David Hogarth's work at Ephesus. In the first era of large-scale excavation the lead was taken by German archaeologists, for by the 1870s archaeology had become a branch of classical studies in German universities. Thus, between 1875 and 1900 the Germans excavated at Olympia in Greece and at Pergamum, Magnesia, Priene and Miletus in Asia Minor; the Austrians at Samothrace (1873) and Ephesus (1894). Other very important excavations started in this period were those of the French at Delos (1877) and Delphi (1892), of the Americans at Corinth (1896) and of the British at Sparta (1906). The Greeks, too, were active: at the healing sanctuary of Epidaurus (1881), at Eleusis (1882) and, most important, on the Acropolis at Athens (1885). From this latter shrine came the wealth of archaic material used as filling after the Persian destruction of its monuments in 480 B.C. Very important discoveries, too, were made outside the field of strictly classical archaeology: the revelation of Mycenaean Greece by Heinrich Schliemann at Troy, Mycenae and Tiryns and of the Minoan culture on Crete by Sir Arthur Evans at Knossos. The complexity of many of these sites still held, in the 1950s, the major attention of the schools located there, but, in addition, a large number of smaller and less well-known places were excavated in the following generation. From these has come important information, for they have frequently been less disturbed by continuous inhabitation and the search for building materials. Generally speaking, the material provided for archaeological studies by the 50 years of activity from 1875 to 1925 enabled the basic outlines of its various branches to be established and much of the detail of classification to be filled in. Thereafter, however, new and ambitious projects were undertaken and a clearer insight was obtained into the problems whose difficulties were revealed by the wholesale excavation of the preceding era.

Later Activity.—A somewhat better understanding of the "Dark Ages" was secured by the correlation of material from small excavations and, in particular, from the German excavation in the Ceramicus (cemetery) of Athens. The latter established the fact that in Athens there was a cultural continuity from Mycenaean times and provided a chronology from the pottery found in the graves. Knowledge of the Archaic period was supplemented by British excavations at Perachora, the site of a small sanctuary near Corinth, and by an Anglo-Turkish dig at Old Smyrna in Asia Minor; this latter promised to provide the first substantial picture of an early settlement of the Greek migrants to Asia Minor—the environment of Homer. Useful information for this period also came from German excavations on Samos, Aegina and Olympia, where much early metalwork has been found. U.S. excavation of the potters' quarter at Corinth and of one of the early cemeteries, overlooked by Julius Caesar's settlers, has thrown light on the pottery industry there at the height of Corinth's commercial activity in the 7th and 6th centuries B.C. The mature periods of Greek and Roman civilization have been clarified by large-

scale U.S. excavation in the market places (agorae) of Athens and of Corinth and by the clearing of the residential quarter of the small Greek city of Olynthus in Macedonia. The Agora excavation in Athens enabled the restoration of the social and political centre of Greece's most famous city and yielded thousands of inscriptions to amplify the details of its history. Scrupulous care in excavation and recording made an elaborate classification of the pottery and figurines of the Hellenistic and Roman periods possible. The continuance of the excavations in Corinth brought the centre of a great Roman city to light, while the town of Olynthus revealed the planning of a classical Greek city and provided much material for a reconstruction of its daily life. Perhaps as an antidote to this understandable affinity for urban centres, U.S. excavators also cleared the exotic sanctuary of the Cabeiri on Samothrace, begun by the Austrians in 1873, and started work on the Isthmian sanctuary near Corinth. Important material for the study of Greek religion was found by the Greeks at Eleusis. Both French and Italians were active at many points in the Aegean area, particularly on the islands of Thasos and of Rhodes and Cos, where large areas of the ancient cities were revealed, while in Asia Minor Swedish archaeologists excavated Labraunda.

B. Excavation in Italy

Early Period.—In Italy the cultural problems of classical archaeology are rather more complicated than in Greece, for Roman civilization was a blend of native Italian, Etruscan and Greek colonial influences in its early period; these fused into Rome of the republic and met the mature civilization of Greece from Hellenistic times onward. In addition, both the colonial Greek area in Sicily and southern Italy and the Etruscan area of central Italy are of extreme interest in their own right. The interrelation of these areas, however, was only realized in the 19th century. At first, of course, it was the visible remains in the city of Rome itself that roused archaeological interest. Unlike Greece, which for centuries was inaccessible to travelers from western Europe, Italy played a leading role in medieval and early modern times so that its monuments profited or suffered accordingly.

An early indication of curiosity about the structures in Rome surviving from the empire was the production of a guidebook for pilgrims, the *Mirabilia urbis Romae*, even before the time of printing. The period of the Renaissance, of course, was characterized by a passionate interest in antiquity. Leaving aside the question of the influence of Roman architecture and sculpture on Renaissance artists, this interest resulted in very material gains for archaeology: the drawings of ancient buildings by architects not only made their principles of construction a part of common knowledge but also preserved on paper buildings which later were destroyed; the interest of sculptors and painters and their patrons preserved many statues from the lime kilns in the search for building materials from the ruins. From the 15th century to the 17th the structures in Rome became literally quarries for building stone, particularly marble. The buildings which had survived the medieval period fell into masses of rubble from this activity, which exported its products as far afield as Westminster abbey in England. While the architecture of ancient Rome thus suffered, its sculpture was treasured, and throughout this period the large collections of the princely families in Italy were formed, partly by excavation on their private estates and partly by purchase. Inscriptions, too, were preserved or copied by the interest of scholars, but excavation remained essentially for the purpose of acquiring precious objects for collection or sale; this motive, rather than any desire for knowledge, led to the excavation of Herculaneum, started in 1738, and to that of Pompeii shortly afterward. Scholarly interest, however, was soon kindled so that the Accademia Ercolanese was founded in 1755. It tried to record the material from the excavation of Herculaneum and published eight volumes of antiquities between 1775 and 1792.

The first landmark in a more scientific approach to excavation was in the work of Carlo Fea in the Forum in 1803 and again in 1813–20. He worked systematically to bring some order out of the rubble heaps left by the search for building stone, recording his findings properly. Similar aims were advocated by the Istituto di Corrispondenza Archeologica, founded in 1829 with an international membership of scholars interested in Roman studies. While this effort had a wholesome effect on excavation, yet such activity was still carried out by private individuals for their own delectation or profit, so that many potentially important finds went unrecorded and large groups of objects were dispersed. It was unfortunately in these circumstances that the archaeological discovery of Etruscan civilization was made. In 1827 the first tombs were opened at Tarquinia and in 1828 at Vulci. These chamber tombs with their vivid wall paintings of Etruscan funeral banquets, games and scenes of religious and daily life were a revelation, as were the rich offerings of vases, ivories and metalwork found in them. Since there was no regulation of their excavation, exploitation was rapid; the tomb groups were frequently broken up and objects dispersed throughout Europe. By 1848 the Etruscan cities were so fully known that G. Dennis' *Cities and Cemeteries of Etruria* could be written and remain the best survey of their monuments. It was not until after the unification of Italy that a firm hand was taken with excavation and antiquities. At that time governmental supervision and conduct of archaeological activity were established. By this time the Istituto di Corrispondenza Archeologica had developed into the German Archaeological institute (1871), and other schools soon followed: the French in 1873, the American academy in 1894 and the British school in 1901. These schools and those founded subsequently, Belgian, Dutch and Swedish, unlike their counterparts in Greece, have seldom been licensed to engage in excavation. Thus, their work has been mainly one of study and interpretation, while excavation has been the task of the Italian governmental departments concerned. From 1876 these activities were duly reported by the official publication of excavations in the *Notizie degli scavi di antichità* of the Royal Academy (Accademia Nazionale dei Lincei). In the two generations which followed, a great amount was accomplished, as in Greece during the same period. In Rome itself the Forum was steadily cleared, and in 1899 excavation began to go below the level of the imperial pavement to investigate the primitive city. The famous *lapis niger* with its archaic inscription was found in 1899. More systematic excavation of the two show places of Italy, Pompeii and Herculaneum, was carried out, as well as major excavations in the Greek colonial sites and on the small towns of the native Italian peoples. In short, the structure of classical archaeology in Italy was worked out and its various problems more clearly formulated.

Later Activity.—The fascist regime in Italy, with its emphasis on the continuity of Roman imperialism, promoted a somewhat flamboyant but very effective archaeological program, particularly in Rome itself. There the Roman Forum and the forums of the emperors were systematically cleared and partially restored as part of the general monumental reorganization of the heart of the city. Elsewhere much work of a similar nature was carried on and new discoveries were made as the result of building activity and clearing the old buildings of accretions. The buildings on the Palatine and Capitoline hills, the Tabularium and the Mausoleum of Hadrian were all made intelligible. Museum collections were reorganized and exhibited to better advantage. Large-scale excavation and restoration were carried out at Pompeii and Herculaneum so that their development was better understood, while their streets and houses were made an almost living monument of the past. Considerable knowledge of the Republican period in Italy was gained by the investigation of such Roman colonies as Ardea, Minturnae and Cumae and by investigation of monuments in Turin and Milan. In the Greek colonies work continued on the known sites and an important new discovery was made on the Silarus (Sele) river, where the Heraion of Lucania was excavated. It brought to light the sculptured metopes, in excellent preservation, of the archaic temples, thus setting a new group of early sculpture alongside that of Selinus, long known. The great cities of north Africa, such as Leptis Magna and Cyrene, were also cleared. This ambitious program was curtailed by World War II, but archaeological activity was quick to revive. In 1945 the International Association for Classical Archaeology was founded in Rome

and in 1946 began the publication of *Fasti Archaeologici*, a complete annual bibliography for classical archaeology as a whole. This international flavour also characterized post-World War II excavation, with the French institute sharing in the digging of Etruscan Bolsena and the Greek colony of Megara Hyblaea, the Belgian school in that of Alba Fucens, a Roman colony, and the American academy in that of Cosa (Ansedonia), a Roman colony on the Etruscan coast. Italian efforts were directed partly to the routine work of restoration and preservation, but on an increasing scale to excavation.

VII. GREEK AND ROMAN ORIENT (INCLUDING EGYPT-INDUS)

Before Alexander the Great.—Greek influence in the orient is very old, going back to the Egyptian Old Kingdom (2680–2258 B.C.) if Pierre Montet is right in identifying the Helou-Nebout with Hellenes. This is doubtful, but in any case, Greek trade with Egypt of the empire became very active in the period of Late Helladic I and II (1560–1300 B.C.). Greek pottery and art patterns are found in Egypt at that time, and such tombs as those of Senmut and Rekhmara at Thebes are decorated with representations of tribute bearers from the Aegean. In Late Helladic III (1300–1200 B.C.) similar finds occur also in the Levant and Mesopotamia.

Following the period of the migrations, about 1200 B.C., in which such Grecian tribes as the Danaans took part, Greeks began to settle on the southern edge of the old Hittite empire in Asia Minor, and the Aeolic and Ionian cities were founded on the eastern shores of the Aegean. In the case of Miletus, there is evidence that Greek occupation goes back to Mycenaean times (before 1200 B.C.). The great Greek colonial movement of the 8th and 7th centuries B.C. added further settlements on the northern and southern shores of the Anatolian peninsula.

Early buildings of this time have been found at Old Smyrna and especially at Ephesus, where the great temple of Artemis was excavated. A few Greek trading posts were established on the Levant coast also. Poseideion (the present Al-Mina) flourished from 800 B.C. until its destruction by Nebuchadrezzar and was refounded as an Attic colony in 520 B.C. The work of Greek artists from Ionia has been detected at Pasargadae and Persepolis, under the early Persian empire (550–500 B.C.). The Lycian tombs of the 5th century B.C., such as the Nereid tomb from Xanthus (in the British museum) and the Harpy tomb from Tyrsa (in Vienna), show the work of Greek sculptors. The Mausoleum at Halicarnassus, one of the Seven Wonders of the World, built about 350 B.C. as a tomb for Prince Maussollus (Mausolus) by his wife Artemisia, was decorated by the Greek sculptors Scopas, Bryaxis, Timotheus and Leochares. In Egypt, Greek artistic influence shows itself a little later, notably in the tomb of Petosiris at Hermopolis Magna (modern El Ashmunein).

Alexander the Great.—Between 334 and 323 B.C., the conquests of Alexander the Great opened the territory of the Persian empire as far east as India to Greek settlement and Greek influence. In consequence of his early death, his immediate archaeological influence is confined to the cities which he founded, usually named "Alexandria." Several of these lay on the sites of later cities in Iran, Afghanistan and the U.S.S.R.: Chodjend, Ghazni, Kandahar, Herat and Merv. Two of those in the west retain their names: Alexandria in Egypt and Alexandretta in Turkey. In addition, Alexander minted a plentiful silver coinage which was to continue for centuries after his death. The common types show Alexander's head with ram's horns in imitation of the god Amon, with a lion headdress as a reminder of Heracles or with an elephant skin in token of his victory over Porus' war elephants in the Indus valley (326 B.C.). In sculpture, Alexander set the fashion of royal portraiture, the rendering of the sculptor Lysippus being especially popular. The famous Alexander mosaic at Pompeii is a copy of a painting by Philoxenus of Eretria.

Hellenistic Period.—Under the Hellenistic states (323–30 B.C.) which succeeded Alexander's unified empire, the process of Hellenization of the orient proceeded methodically. The kings of the Ptolemaic (in Egypt) and the Seleucid (in Asia) dynasties were Macedonian generals; foreigners in the territories which they ruled. They needed Macedonian and Greek soldiers and Greek technicians, executives, artists, businessmen and settlers in order to administer and to maintain their kingdoms. These collected at the royal courts and populated new cities or new quarters of old cities, forming islands of Greeks loyal to the ruling dynasties amid a sea of hostile or indifferent natives. The same situation prevailed in the minor kingdoms of the Attalids of Pergamum in northwest Asia Minor, near the Greek motherland, and of the Greek kings of Bactria and India on both sides of the Hindu Kush, who certainly attracted very few Greek immigrants.

It is probable that none of the kings attempted to Hellenize his native subjects as a policy, except perhaps Antiochus IV of Syria (175–163 B.C.), best known for his conflict with the Jews (and he was thought to be mad), but their use of the Greek language and their encouragement of Greek culture had an inevitable effect. An Egyptian complains about the year 255 B.C. that he met discrimination in his employment "because he did not know how to act like a Greek." For the same reason, Greek ways spread to the Hellenistic states which were Iranian in nationality, such as that of the Parthians, who dated their kingdom from 248 B.C. and officially described themselves as philhellene (pro-Greek), and to those with Iranian ruling families: the kingdoms of Bithynia, Pontus and Cappadocia in Asia Minor. Even the cantonal state of the invading Galatians with its capital at Ankara was gradually Hellenized, and the Maccabean movement in 2nd-century Judaea began as a protest against Hellenizing tendencies among the Jews. This Hellenistic process gives a unifying quality to the whole period. The Hellenistic peoples shared a common culture as they shared a common dialect, the so-called Koine, in which the Greek New Testament is written.

In the field of architecture and town planning, the finest remains of this period are found in Asia Minor. The little town of Priene, perched on the slope of a steep ridge north of the Maeander river not far from its mouth, was built largely with the support of the kings Alexander the Great and Lysimachus of Thrace (301–281 B.C.). The construction is of stone throughout, and the city is laid out according to the plan popularized by the architect Hippodamus of Miletus (5th century B.C.) in rectangular blocks, each containing typically four private houses. The streets are straight and intersect at right angles, opening out at times for a beautiful little theatre and Ionic temple of Athena, for a market place with colonnades and a public meeting hall, and, at the lowest part of the town, for a gymnasium and stadium, the whole being inclosed within a city wall of finely fitted stone.

More spectacular is the site of Pergamum. This was the Attalid capital and fortress, built on the top of a high and isolated hill. Its buildings belong to the period 250–170 B.C. and, as excavated by the German Archaeological institute, are principally of a public character. The palace of the kings has been discovered, standing with extensive storehouses and arsenals on the crest of the hill. The slopes are occupied by temples, a library, gymnasium, a large theatre and the so-called Great Altar, the reliefs of which constitute the most remarkable examples of Hellenistic sculpture. They represent the battle of the gods and giants, expressed with great vigour and emotion, and were formerly on exhibition in the Pergamum museum in Berlin.

Elsewhere in Asia Minor, extensive Hellenistic remains exist at Miletus, at Heraclea on Mt. Latmus (famous for its well-preserved fortifications), at Aezani in Phrygia, at Attaleia (Adalia) in Pamphylia and at such hill towns as Theangela in Caria.

In Egypt and the east, the only Hellenistic city to have been excavated systematically is Doura-Europos on the middle Euphrates, a garrison town built about 300 B.C. of poor stone, rubble and mud brick, which had little importance in the Hellenistic period. It was laid out according to the Hippodamian plan, with a rectangular market place in the centre. The same was probably true also of such great Seleucid cities as Laodicea (Latakia) in Syria, Antioch in southern Turkey, Seleucia on the Tigris near Baghdad and Susa on the Eulaeus (Karun) in Khuzistan (Iran), but little of the Hellenistic period has been found in these cities.

The same city plan is still visible in Alexandria, Egy., built on the coast west of the Nile delta at a point where an island and connecting causeway made a double harbor. The island was the site of the lighthouse or Pharos, and the city itself, long and narrow, included quarters for the Greek, Egyptian and Jewish inhabitants and a royal quarter, the site of the museum and library. The Serapeum or temple of the god Serapis, who had been created by Ptolemy I (323–285 B.C.) for his Greek and Egyptian subjects, has been found in the southern part of the city, at a place called Pompey's Pillar. Little remains except the underground rooms and vaults, but the gold foundation tablet has been found, dating the construction to the times of Ptolemy III (246–221 B.C.). Elsewhere in Egypt, the Ptolemies continued to build temples in the traditional Egyptian manner. That at Edfu in upper Egypt is almost completely preserved and is covered with accounts of the temple ritual in hieroglyphic writing. Of the cities and villages built for immigrant Greeks, little remains except along the edge of the Fayum oasis, near Cairo, where several settlements with stone temples and crowded houses of mud brick have been partially excavated.

It is to archaeological materials that we owe much of our knowledge of the Hellenistic orient, especially to the inscriptions on stone which have preserved laws and decrees of the cities or letters of the kings, and to the papyrus documents from Egypt comprising laws, royal edicts, court decisions and official papers of all sorts, as well as private letters, accounts, contracts and deeds and memorandums, with substantial fragments of Greek literature, preserved in large numbers by the dry climate.

The silver coinage of the Hellenistic rulers was plentiful and artistic, and supplies much useful historical information. Some of the coins, especially those of the Bactrian kings, contain royal portraits of great beauty. Pottery of the period is of no special interest, except for the fine red bowls of the so-called Samian and Megarian ware, decorated with bizarre scenes in relief. Similar metalwork was popular but has disappeared for the most part. Gem cutting and polychrome jewelry became popular. The standard containers of the period were large, five-gallon clay amphorae, the handles of which were often stamped with dates or indications of origin; these serve as indexes of the flow of trade in grain, wine and olive oil. Glass blowing was discovered in the Hellenistic period, and many fine bottles and bowls were made in Syria and Egypt.

In the field of engineering, the Hellenistic period saw such improvements in irrigation as the Archimedean screw for raising water, and made great advances in the production of large ships of war and of siege engines and artillery.

In the field of fine arts, paintings, mosaics and frescoes have perished except rarely in Egypt, where the painted mummy portraits preserve fine likenesses of men and women, but Hellenistic sculpture survives, directly or in the form of Roman copies. Among the latter are many portraits of Alexander and the kings, of famous philosophers and men of literature. There are Venuses of various types, Muses, Dying Gauls, copies of the head of Serapis designed by the Rhodian school, and city Fortunes based on Eutychides' Antioch with turreted crown or Sophilus' Alexandria with headdress in the likeness of the prow of a ship. Notable originals which have survived, in addition to the reliefs of the Great Altar at Pergamum, are such Venuses as those from Melos (in the Louvre) and from Cyrene (Museo delle Terme in Rome), and the great Laocoön group made in Rome by Rhodian artists toward the end of the Hellenistic period. As a smaller equivalent of the large statuary in marble and bronze, little clay figurines were very popular and have survived in large numbers. They represent fashionable ladies and gentlemen, children, slaves, animals and grotesque subjects of many kinds. The centres of manufacture were Tanagra in Greece, Myrina in Asia Minor and Alexandria in Egypt.

The Roman Empire.—The period of the Roman empire (27 B.C.–A.D. 476) is marked in the orient by recovery and expansion followed by stagnation and decay. The Roman civil wars of the 1st century B.C. had caused terrible damage in the east, and after Octavian's final victory before Alexandria in Aug., 30 B.C. the Hellenistic orient was prostrate. The Iranian kingdom of Parthia had benefited by the collapse of the Seleucid state to expand as far west as the Euphrates river, and small native kingdoms had established themselves in the buffer zone between the Roman west and the Iranian east: Commagene in the Amanus mountains, famous for the funeral monument of King Antiochus on Nimrud-Dagh; Judaea under the Herods of Idumaea, well known from the Bible, the writings of Flavius Josephus and the papyri and parchments found between 1948 and 1952 in the Dead sea caves; and Arabia under the Nabataean Arabs, with their spectacular capital at Petra in the modern kingdom of Jordan. The caravan city of Palmyra flourished in the Syrian desert.

With Augustus' settlement with the Parthians in 20 B.C., a state of peace prevailed between Rome and the Iranians for almost 250 years, interrupted by brief border wars under the emperors Nero, Trajan, Marcus Aurelius and Septimius Severus. Trajan added to the empire the province of Arabia (modern Jordan) in A.D. 106 and Septimius that of Mesopotamia (the Syrian Jazira) in A.D. 198–199, and Armenia as a client kingdom was sometimes under Roman, sometimes under Parthian control. About A.D. 224, the philhellene Parthian dynasty was superseded by the fanatical Sassanian Persians of Fars, and Rome's wars with its eastern neighbour became more serious, the Sassanians entering Antioch more than once about the middle of the 3rd century and capturing the emperor Valerian about A.D. 260. Nevertheless these were limited wars which did not affect seriously the Greco-Roman population of Asia Minor, the Levant and Egypt, which were free to prosper from manufacturing, trade and commerce, troubled only by the growing burden of Roman taxation and Roman bureaucracy. Even the Gothic raid in Asia Minor in A.D. 267 did little damage, while the central part of the peninsula benefited from the activity of the great military road from Byzantium to Antioch. These were the centuries of great building activity in the orient. Existing cities were expanded and new ones were built, especially in central and southern Asia Minor, Mesopotamia, Jordan and southern Palestine. In all of the orient, remains of buildings, walls, bridges and aqueducts built of rubble, stone or baked brick illustrate the Roman fondness for massive construction with arch and vault, while the traces of Roman paved roads and frontier military posts are found commonly along the frontier.

In the field of art, on the other hand, the Roman period in the east is less distinguished. Mass production of metal objects, glass and pottery, cloth and jewelry meant that artistic excellence was sacrificed for cheapness and plenty. Roman figurines are dull compared with the earlier Hellenistic product. Roman coins cannot compare in artistic quality with those of the Hellenistic kingdoms, and in the 2nd century began a process of depreciation in silver content which led to the enormous price inflation of the period following A.D. 270. In the plastic arts, the popular subjects are those connected with the oriental religions of Egyptian, Syrian and Iranian character which now began to spread to the west. Figurines and sculptures represent the oriental deities, principally Isis, Osiris and Serapis of Egypt, with such mixed Greco-Egyptian conceptions as the popular Harpocrates; the Levantine Baal, Astarte and Atargatis, Adonis, Dusares, Bel, Jupiter Heliopolitanus and Jupiter Dolichenus; the Iranian Mithras; and the Anatolian Great Mother and Attis. The one great artistic creation was that of the god Mithras slaying a bull, which became the Mithraic central cult image and which has been found in numerous renderings throughout the many centres of worship of this god in the west. Farther east, the old Hellenistic creativeness showed itself in Iranian clothing, in the royal Sassanian rock reliefs and in the

service of native religious ideas in India, where the portrait of the Buddha of the so-called Gandhara art became standard for centuries to come.

The general mediocrity of art in the Roman orient is brightened by the artistic excellence of the mosaic pavements found in Antioch, with their geometric and floral polychrome patterns and their rendering of religious and rural scenes. Of even greater interest are the frescoes found at Doura-Europos, small and primitive ones from a Christian chapel and large and elaborate ones from a Jewish synagogue, both belonging to the period about A.D. 250. The Christian scenes portray the Good Shepherd, the healing of the paralytic, Christ walking on the water and some other subjects. The Jewish frescoes cover the entire walls of a large room and present numerous scenes from the Old Testament, especially those connected with Moses, Esther and the Ark of the Covenant. The Christian chapel has been re-erected in the Art gallery of Yale university, the synagogue in the museum of Damascus.

Roman building in the east reached its height in the 2nd century but was matched under the Byzantine emperors in the 5th and 6th centuries, when many monumental structures were converted into churches. This is true at Ephesus, on the Aegean coast of Asia Minor, and at Gerasa (Jerash) in Jordan, two of the finest sites of the Roman east. At Baalbek in Lebanon, the citadel of the Roman city was preserved largely by the Christian buildings erected in it, and the smaller temple of Bacchus, as well as the great temple of Zeus with its large court and lofty altar, remain to impress us with their magnificent proportions and the richness of their sculptured decoration. Scenically, however, the finest ruins of the Roman orient lie in the desert, the little-visited Hatra in Iraq and especially Palmyra, "the Bride of the Desert," on the road between Damascus and the Euphrates. There the remains of temples, colonnaded streets, theatre, council chamber, forum and caravanserai, and the great temple complex of the god Bel, in their colourful desert setting, linger in the memories of all visitors.

(C. B. Ws.)

VIII. THE IRON AGE IN EUROPE

The Chronological Framework.—Outside pre-Classical Greece the first use of iron occurred in the late Urn Field culture of Italy and central Europe (Reinecke phase B). The iron was imported and used to imitate or decorate traditional bronze types. Only in the next phase does it come into regular use. Its use spread only slowly across Europe, an important factor being the rate of production of separate mining centres.

Since the commencing date of the Iron Age varies from place to place, the division into an early and a late period also varies. The central European early Iron Age is contemporary with the late Bronze Age of northern Europe. Absolute dating in Italy is therefore calculated in relation to the foundation there of the Greek colonies (after 750 B.C.). By correlating other cultures to this, the end of the Urn Field culture and the beginning of the Iron Age is established at about 800–750 B.C.

The end of the prehistoric Iron Age is marked by the Roman expansion in the Alpine zone as far as the Danube (16–15 B.C.), bringing Italy, France and southeastern Spain into the period of written history.

The Celtic migration about 400 B.C., spreading the La Tène culture, marks the division between early and late Iron Age.

Origin and Production of Iron in Prehistoric Europe.—A letter of Chattusil III to Amenhotep II shows that during the 15th century B.C. iron was mined and used to make implements in southeast Asia Minor. The use of iron may therefore have diffused from there into early classical Greece and thence to the neighbouring nonliterate peoples. W. Witter, however, showed that the copper mines which were in use from the early Bronze Age in central Europe also contained (sparry) iron ores, which the miners may have tried to process separately; but this has not yet been proved. All known examples of central European iron mining belong to the end of the Iron Age; *e.g.*, eastern Alps (Burgenland), Bavaria (Kelheimer Forst, Donaumoos near Augsburg and the west German Siegerland. Furnaces in north Germany and Scandinavia show the use of bog ore (limonite). Roman mines in the eastern Alps (Erzberg, or Ore mountain, near Eisenerz and Hüttenberg) may have been used already in the Iron Age. Iron was bloomed in bowl furnaces, producing a very impure iron. The iron was marketed in the late Iron Age as biconical bars with drawn out ends or as flat bars.

Significance of the Urn Field Culture.—The character of the Urn Field culture was influential on the history of early Iron Age Europe. The core of the Urn Field culture extended from central Germany to the Alps and from eastern France to western Hungary. Its marginal areas covered north and central Italy, southeastern France, northeastern Spain, Belgium, the Netherlands, eastern England, northern Germany, Denmark, southern Sweden, Poland, Hungary and Macedonia. Traditional forms in pottery and metal persisted into the early Iron Age in these areas. The uniformity of the Urn Field culture suggests that it represents the extent of migration of one people.

Early Iron Age and Its Different Cultures.—The two most important centres in the early Iron Age are central and northern Italy and central Europe, where a culture based on iron became established while the rest of Europe was using bronze. Archaeological evidence suggests that the early Iron Age peoples of Italy developed their characteristic cultures on the spot and were not immigrant groups as has been suggested on linguistic grounds.

Etruscans.—The Etruscans were a mixed stock derived from the native Mediterranean non-Indo-European element existing from Neolithic times, blended with Indo-Europeans who reached middle Italy in the wake of the Urn Field culture; their language reflects this. From the mid-8th century B.C. the culture of central

Italy is enriched by Phoenician-Egyptian imports, particularly on the west coast. The transition stage is seen in cemeteries at Timmari, Tolfa and Allumiere and Pianello di Genga (cremations with Urn Field pottery). The earliest Etruscan element is found in cremation burials in shaftlike pits (*pozzi*) from Tarquinia (Corneto), Veii and Vetulonia. Later inhumations in rectangular ditches (fosses) also occur, from which the typical Etruscan tomb develops, based on chambered tombs, which allow mural decoration (Tomba dei Tori, degli Auguri, delle Vasi Dipinti, dei Leopardi, del Letto Funebre, dell Orco). Cremations in figure-shaped urns (canopi) continue well into the 6th century in the Etruscan hinterland, but simple rock-cut chamber tombs were also used. The chronology is related to a series of standard tombs, beginning with the Tomba del Guerriero (Tarquinia), a late fosse, with geometric pottery (*c.* 720–710 B.C.). Then follow: the Bocchoris (Bokenranf) tomb (Tarquinia), an early chambered tomb containing an Egyptian faïence vase (700–690 B.C.); the Tomba del Duce (Vetulonia) (*c.* 680 B.C.), from which the grave goods show the beginnings of orientalizing decoration. This decoration is continued (675–625 B.C.) in the chambered tombs Regolini-Galassi (Caere), Barbarini and Bernardini (Praeneste), which were lavishly furnished; *e.g.*, with Phoenician silver bowls. The figural motifs from them were copied by the Etruscans on ivories (Pania tomb in Clusium). As Etruscan supremacy spread northward this art reached the Villanovans and Atestines, who used it on situlae.

Villanovans.—Villanova, a small suburb of Bologna, yielded the first north Italian early Iron Age burials and thus gave its name to the culture in the provinces of Bologna, Faienza, Forli and Ravenna, as far as the Reno and Panaro rivers. The Villanovans arose from a mixing of Lake Dwelling and Terramare peoples with Urn Field peoples from the 10th century B.C. onward. The Villanovan cemeteries are named after the owners of the land where they were found. The early period is Benacci (comprising phases I and II), the first phase of the late period is named Arnoaldi, the final phase being Certosa. Benacci I and II practised cremation burial almost exclusively; inhumation gradually became customary during Arnoaldi, spreading still more during Certosa. But cremation burials in urns and in large barrel-shaped vessels (*tombe a dolio*) continued. The Benacci I urns are still comparatively plain, being closely related to the pottery of the Urn Field culture. During Benacci II they are more delicately formed and copied in bronze, new forms appearing (situlae, cists and bowls). The cultural standard rises during Arnoaldi, and by Certosa the culture has become Etruscan. Thus figural decoration of bronze vessels spread north of the Apennines, from which comes the Certosa situla, a masterpiece of embossed work. It has a late successor in the Arnoaldi situla of the 5th century B.C., which already shows traces of Celtic craftsmanship. The Celtic invasions after 400 B.C. determine the end of the Villanovans.

Golaseccans or Comacines.—Named after Golasecca, on the left bank of the Ticino river, this culture covers the region of lakes in northern Italy and southern Switzerland, as well as the valley of Lombardy and Piedmont as far as Liguria. Its origin is similar to that of the Villanovan, with the Urn Field element more modified by the native Ligurian tradition. The geographical position of the Comacines permits a less detailed chronology. Phases I and II correspond to the period from Benacci I to Certosa. Phase III belongs to the late Iron Age. The pottery of phases I and II is closely linked with the Urn Field culture pottery and serves as cremation urns. Ornamented bronze vessels from the Villanovans or Atestines occasionally appear in phase II and were imitated (*e.g.*, situla of Sesto Calende).

Atestines.—This culture is centred on Este (ancient Ateste) and extends over Venetia into the Balkans. It is rooted in the Urn Field culture, and its possessors are usually identified with the Veneti. Four phases are distinguished; Este I is ill-defined, Este II has an individual character, Este III is the climax corresponding to Certosa, and Este IV shows Celtic influences. The culture was terminated by the Roman occupation of the territory in 183 B.C. The Atestines developed the decoration of situlae (*e.g.*, situlae Benvenuti, Rebato, Prà d'Este, Boldu-Dolfin), an art which they learned from the Etruscans. Their products were traded as far as the Hallstatt Illyrians (*e.g.*, situla lid from Hallstatt) and the Balkan Illyrians (situlae of Vace, Magdalenska Gora, etc.).

Picenes.—This culture spread on the Adriatic coast of central Italy around Novilara near Pesaro. The pre-Urn Field traditions, especially of inhumation, remained strong, and there were cultural links with the opposite mainland. Two phases can be distinguished, the Molaroni and the Servici. Grave goods are similar to those of central and northern Italy, but pendant ornaments are preferred. The pottery, however, is characteristic. From the 6th century comes the stone statue from Capestrano inscribed "Magubregaeque hoc monumentum Raginevique S. . . . i." The two names are Picenian.

Hallstatt Illyrians.—The Hallstatt culture, named from more than 2,000 tombs found at Hallstatt, spread far over central Europe, from eastern France to Austria. It is divided into western, northern and eastern, with further local subdivisions. These regional distinctions reflect variations in the Urn Field culture and proximity to northern Italy. It derived from the late Urn Field culture and was at its prime from the 7th to the 5th centuries B.C. In the sub-Alpine region it was ended by the Celtic migrations about 400 B.C., but it continued to the early years A.D. in the central Alpine range.

The Hallstatt necropolis furnishes a cultural sequence for the western group. Iron is increasingly used for weapons, ornaments and tools, but bronze continues in use for ornaments (especially belt fittings). Bronze vessels are still made, but imports from the Atestines are also found (*e.g.*, Hallstatt situla lid). Pottery tends toward ostentation, and the graves show distinctions of class. The Celts originated within the western group during the 5th century B.C.

Lusatian Illyrians.—The early Iron Age culture of central Germany and Silesia, centre of diffusion of the Urn Field culture, shows a direct descent from that culture and has very few iron implements. Its area includes western Poland. Vessels are painted in imitation of those of the Hallstatt Illyrians but are inferior. The Lusatian Illyrian culture was comparatively simple.

Balkan Illyrians.—The region occupied by the Balkan Illyrians corresponds to the Roman province of Illyricum. It is the hinterland of Classical Greece and bordered by the Hallstatt Illyrians and Thracians and influenced by the Atestines. This causes a threefold division of the Balkan Illyrian culture—the Vace group in Carniola, the Nesazio group in Istria and the Glasinac group in Serbia, continuing into Macedonia. Vace and Glasinac pottery is similar to Hallstatt, while Nesazio pottery shows Atestine influences. Bronze embossing is carried on by the Nesazio group. The Vace and Glasinac groups prefer pendant ornaments. There is very little Celtic influence throughout the area, so the culture continues at least to the Roman occupation (2nd century B.C.).

Thraco-Cimmerians.—Southern Hungary and Rumania are influenced from the 6th century onward by the Scythians advancing from south Russia. From this area came the famous gold treasure of Michalkow (Galicia) and finds of Fokoru (Hungary) and Vlci Trn (Bulgaria). The knotted bow of the Michalkow fibulae places the find in the culminating phase of the early Iron Age, during which a specific culture is found in the region, parallel to the Hallstatt and Balkan Illyrian. Literary evidence permits the naming of this group as the Thraco-Cimmerians, from among whom the Dacian power arose and threatened the Celts toward the end of the late Iron Age.

Late Bronze Age in Northern Germany and Southern Scandinavia.—The contemporary culture of northern Europe was ignorant of iron and continued its late Bronze Age culture (Montelius IV–VI), rich in bronze implements often of complicated manufacture (*e.g.*, large trumpets or luren). During Montelius phase IV it shows strong influence from the central European Urn Field culture, but in phase V the culture and its bearers spread east and southeast, establishing contact during phase VI with the Hallstatt Illyrians. In view of these movements we may consider the Scandinavian migrants of the late Bronze Age as well as of the early Iron Age to be Germanic.

The idea of evolution was slowly accepted, accompanied by many rancorous disputes. The chief accomplishment of the period between 1859 and 1900 lay in the recognition of a considerable time depth for man. The system of arranging the primates remained unilinear, but it was extended far back into the geological past. Both fossil races of man and contemporary races were arranged according to their assumed degree of morphological primitiveness. The findings of extinct forms of animals by paleontologists, the excavation of older cultures by archaeologists and the discovery of Neanderthal skulls all contributed to questioning the scriptural authorities who credited the world with being only approximately 6,000 years old. Combined researches of geologists, paleontologists, archaeologists and physical anthropologists finally established the antiquity of man as well as of other forms of organic life and thus the evolutionary sequence became of foremost interest. The first recognized discovery of the extinct race of Neanderthal man was made in 1856 in northwestern Germany and was disputed by many persons, including the great German pathologist and physical anthropologist Rudolf Virchow. An earlier discovery of a Neanderthal skull in Gibraltar in 1848 had been largely ignored. The continuing search for more primitive specimens of fossil man was richly rewarded when in 1891–92 Eugène Dubois discovered the Java ape man, now classified as *Pithecanthropus erectus*, considered one of the earliest known races of man.

4. New Approach.—By the end of the 19th century several useful classifications of all the races of the world had been completed. Many of the differences between the races were quite well known. Similarly, differences between man and the anthropoid apes had been inventoried and also between modern man and fossil man. A great deal of attention was paid to the number of differences and it was assumed that the degree of relatedness was adequately indicated by the degree of morphological similarity.

The year 1900 may be taken as a turning point in the development of a new conceptual approach, although no single date can fully comprehend a shift in such an exceedingly complex continuum. Two major events took place which were to have far-reaching consequences: (1) the rediscovery of G. J. Mendel's two genetic principles by several investigators and (2) K. Landsteiner's discovery of the ABO blood groups. Mendel had formulated the basic principles of heredity in 1865 but these had passed unnoticed. The inheritance of the blood groups was not at first appreciated, but within ten years became a focus of research and thus a building stone in modern racial studies. Many new concepts came into use with the increasing influence of genetic theory, such as the breeding population, genetic equilibrium, genetic drift and the gene frequency method of differentiating populations or races. Attention was immediately directed to the processes of change, those ways in which gene frequencies are modified. At the same time increasing attention was paid to the significance of traits and to the ways in which they were interrelated. Experimental studies were devised to demonstrate the functional significance of differences in morphology. The concept of straight-line evolution (orthogenesis) was qualified and examples of reversals or major shifts in the direction of evolution were objectively examined. The concept of the missing link went into discard.

The realization that a change in way of life which introduced a species to a new "adaptive plateau" and brought about many radical changes in its structure obviated the need for a belief in so-called missing links. The techniques of anthropometry were reinforced by many other techniques, such as blood typing, so that the physical anthropologists had a much more versatile set of research tools.

5. Statistical Methods.—Spanning both the pre-evolutionary and the evolutionary periods of physical anthropology was the development of statistics and their application to the measurement of man, included under biometry. As early as 1835, L. A. J. Quételet (1796–1874) had applied the statistical concept of the normal probability curve to human beings. He demonstrated that most of the statures in a population will cluster about a mean and that the frequency of both taller and shorter statures will diminish in frequency at opposite ends of the curve. Sir Francis Galton (1822–1911) succeeded in constructing new measures of variability, correlation and regression. Galton also investigated certain aspects of human heredity. Karl Pearson (1857–1936) classified the types of distribution, perfected the coefficient of correlation, developed chi-square and was a founder of the journal *Biometrika*. Not the least of his many contributions consisted in separating the sample from the population it represented and indicating the necessary restrictions for interpreting a population in the light of information drawn from the sample. R. A. Fisher, continuing the development of modern statistical theory initiated by Pearson, made extensive contributions in the design of experiments and to the field of genetics. One of the trends in the anthropological use of statistics is toward those kinds that preserve the description of the organism as a whole. Analysis of variance, multiple regressions, discriminate functions, generalized distance and factor analysis all share the criterion of treating different variates as a single coherent vector. Unfortunately, the finest statistical treatment will not compensate for poorly selected units of observation or measurement.

C. Problems of Trait Definition and Evaluation

1. Introduction.—A major problem in physical anthropology is that of the trait or unit of observation to be employed. Different inferences are based on the same traits as a result of a different evaluation of them. Also, different traits are cited for the same specimens evaluated by different researchers. The essential difference between the anthropoid ape theory of human origin and the catarrhine monkey theory rests in the different evaluation of traits. The old method of simply enumerating differences did not contribute to the meaning of the differences or indicate the way in which they came into being. The realization that not all traits are of equal taxonomic value made necessary the development of systems, compatible with genetic theory, that would provide an objective basis for the evaluation of traits. Traits commonly used may be categorized into relatively few classes: (1) items which are present or absent, such as an eighth bone in the wrist, a muscle or a particular blood group; (2) proportions such as the relatively greater length of forearm and lower leg in the Negroes as contrasted with Mongoloids; (3) sequence in growth, such as the order of tooth emergency or suture closure; (4) growth rates, such as differences in the attainment of maturity; (5) conformations such as the jutting cheekbones of the Mongoloids; (6) size, such as the differences in stature between Pygmies and Bantu Negroes or differences between sexes and races in cranial capacity. A functional complex constitutes a trait in the sense that the complex as a whole is the object of selection. The above kinds of traits are often compared by frequency. Thus the gibbons have ischial callosities whereas only 36% of chimpanzees show the same denuded areas of thickened skin on the posterior.

2. Measurements.—The problem of what to measure or, perhaps more commonly, what a series of measurements means after it has been assiduously collected, is omnipresent. In many cases it has been found that what was formerly treated as a single unit is actually composed of discrete, isolable elements. The practical meaning is that an over-all observation or a single measurement may conceal important differences and, conversely, that several observations or measurements may actually be different aspects of the same phenomenon. An example of the former is provided in various measurements of the head. The same proportion of head length to head breadth (cephalic index) may result from different measurements. Thus, roundheaded persons may be so because of a relatively short head length or of a great head breadth and great head length. (Pygmies of New Guinea have a cephalic index of 83.4 and the Aleuts have a similar ratio of length to breadth, yet the actual dimensions are considerably less in the Pygmies.) Again, cranial length will often be the same but the different bones of the vault will contribute different amounts to the total length. It has been shown that an over-all measurement of iliac height does not portray the difference between male and female as sensitively as the separate measurements of lower and upper iliac height. The upper iliac height is greater in males whereas the lower iliac height is greater in females.

Examination of research into methods of distinguishing sex in

the pelvis provides examples of the fact that many traditional observations have been treated as independent observations when in fact they were simply different aspects of the same things. It had been common practice to distinguish male from female pelves by observing approximately 17 characters. S. L. Washburn demonstrated the interdependence of many of these characters and analyzed the sex differences into three separate and relatively independent systems. Several characters are dependent on the growth of one of the three elements of the pelvis, the pubic bone. This bone is responsive to female hormone and consequently grows longer in females than in males. The lengthening of this element alters three other characters, the subpubic angle, height of the pubic symphysis and shape of the obturator foramen. An index based on the length of the pubic bone and one other element of the pelvis, the ischium, will determine the sex of more than 90% of skeletons. To this ischium-pubic index may be added the sciatic notch, a character of independent development and evolutionary history. It is broader in females than in males. This difference represents an adjustment to erect posture that was necessarily different in females for obstetrical reasons. A third kind of character is the size of the socket which receives the head of the thigh bone. It is larger in males than in females. The absolute size difference between male and female may also be observed in the ischial element of the pelvis. The use of these three fundamentally different kinds of characters will determine the sex of pelves accurately and economically. The use of the 17 or more traditional characteristics includes many unnecessary observations which are simply aspects of these three basic characters.

3. Experimental Methods.—Attention to the definition of traits and their significance for both evolutionary and racial studies has led to a more general use of experimental techniques and this constitutes one of the trends in the newer physical anthropology. These experimental methods include use of the split-line technique, a way of showing the mechanical arrangement of the bone, the stress-coat technique, alizarin vital stain, removal of bone or teeth, excision of muscles, inactivation of muscles, etc. Other methods of factoring the complexes of interdependent traits are: (1) comparison of contemporary forms and of fossil forms; (2) individual development including embryology; (3) observation of the variations normally occurring in populations, and the variations which occur in disease.

4. Evaluation.—Traits have been evaluated in many different ways. They have been assessed as generalized or primitive as opposed to specialized. An example is the hand, which has remained similar to the earliest known primate hands, whereas the foot has become specialized for walking and has lost its former mobility. Traits have also been divided into those that are adaptive as opposed to nonadaptive. This division is recognized as being difficult to demonstrate. Further, nonadaptive traits would be of limited theoretical value if evolution were dependent on the selection of forms which were adapted to a particular ecological zone. One of the useful approaches to this problem rests on the explicit premise that the "major force in evolution is selection of functional complexes." (S. L. Washburn, "The New Physical Anthropology," *Transactions* of the New York Academy of Sciences, series ii, vol. 13, no. 7, p. 300 [1951].) Adaptation of a group of animals to a particular way of life, an adaptive zone, has been achieved by alterations in a complex of skeletal and muscular traits.

Primary characters are the most important characters; *i.e.*, those which have made an evolutionary radiation possible. The primary character or adaptation responsible for the origin of man appears to have been a new kind of pelvis. Bipedal locomotion depends on a pelvis which provides the necessary points of origin for muscles in positions which enable them to operate efficiently in standing position and in walking rather than the inefficient shuffling seen in the apes. Secondary characters are a consequence of the new selection and are based on the primary characters. These are composed of such changes as the enlargement of the anterior muscles of the thigh, stabilization of the knee and ankle joints and a broadening of the heel bone. A third category of incidental characters is the relatively minor associated differences which have few or no functional implications; *e.g.*, the number of articular facets on the heel bone. The significance of the short broad ilium (upper portion of the hipbone) of man, compared with the high narrow ilium of the apes, lies in the fact that the muscles have been rearranged so that man can extend his leg with considerable power and finish his step with drive. The ape must walk with a bent-knee gait and cannot push forward or complete extension of the leg with real power. The principal muscle involved is the *gluteus maximus*. In the apes this is a small muscle and in a position where it cannot exercise the same leverage as in man. Thus, the differences between man and the apes may be viewed in terms of primary adaptation to different adaptive plateaus. Once man entered a new adaptive zone, characterized by bipedalism or erect posture, selection for this new manner of locomotion brought about many ancillary or secondary changes. The differences, then, take on an interpretable significance when they are related to a complex, and such a complex has evolutionary meaning. On the basis of erect posture and bipedal walking man has become a distinctive genus. Thus we have the evolution of a new genera in a relatively short period of approximately 1,000,000 years.

Each of the other major primate groups may be distinguished on the bases of the distinctive complexes which contributed to its branching off as an adaptive radiation. Thus, the anthropoid apes are adapted for brachiation, a complex which is still retained in large part. The monkeys and the lemurs do not, however, share this functional complex. The development of stereoscopic vision and the enlargement of the corresponding areas of the brain characterizes a complex which was the basis for the development of the monkeys. This is shared with the apes and man but not with the lemurs. The lemurs in turn have a complex characterized by a prehensile hand which is also possessed by the monkey, apes and man. Knowing the fossil record of primates and the major functional complexes which characterize the living primates, it can be seen that man's body has been dissected by evolution and that these four areas have evolved at different times and are shared only with those primates that underwent the same radiations.

The Four Adaptive Radiations Leading to the Contemporary Primates

Major functional complex	Lemur	Monkey	Ape	Man
Hand	x	x	x	x
Stereoscopic vision	–	x	x	x
Brachiation	–	–	x	x
Bipedalism	–	–	–	x

The concept of parallelism has been of great theoretical value in understanding several similarities. Thus, the South American spider monkey is the one monkey in the world capable of brachiation. It has acquired this ability quite independently of the apes of Asia and Africa. Parallelism is not simply a way of discounting resemblances; it also provides examples of the way in which similar selection on related animals produces similar results.

D. Fossil Record of Man's Evolution

1. South African Australopithecinae.—Interpreting the fossil record of man's evolution has been considerably facilitated by the increasing discovery of many new skeletal remains and by especially significant forms. A substantial background has been provided by the incredibly rich finds of the Australopithecinae of south Africa. Often referred to as man apes they may well constitute the first representative of man. Possessing a cranium with mixed ape and human characters, their skeletons provided important answers to questions concerning the human form. Fossil men were recovered in clusters numbering from 3 to 13 or more and, consequently, it is no longer necessary to place as much reliance upon the necessarily enigmatic single skull remains such as that of Rhodesian man or the Heidelberg mandible. It is possible to secure a reasonable synopsis of the major outlines of cranial transformation without resorting to evidence of past races represented by only one skull or skeleton. The importance of this rests in the fact that no single individual, living or skeletal, can represent a population. The authenticity of single skulls has usually become a major question, often obscuring the possible significance present

Western Europe.—There is no cultural uniformity to the west of the Hallstatt Illyrians, though there are two main zones. Central and southern France and northwestern Spain form the first zone, with a culture developed from the west European Bronze Age influenced by Urn Field and Hallstatt elements. The persistence of cremation permits the name Cremation Burial culture. Outstanding material comes from the tombs around Narbonne, from the Ger plateau and from Ávila, Guadalajara, Saragossa and Soria. In the 4th century B.C. La Tène elements appear, though the Celtic migration did not cause any break in this culture except in southern France. At the southern foot of the Pyrenees it may have lasted until the end of the late Iron Age, while in northern Spain it was probably absorbed into the Iberian culture during the 3rd century B.C.

In the second zone, consisting of western France, the rest of the Iberian peninsula and the British Isles, the Atlantic Bronze Age culture continues, with elaborate implements often found in hoards. The older pottery types persist—food vessel, cinerary urn, incense cup. Noticeable change occurs only during the 5th century B.C., when the Celtic migrations began.

Late Iron Age and Its Cultures.—Outside Greece and Italy the European late Iron Age begins during the 5th century B.C., when the Celtic La Tène culture begins to migrate, uniting what had previously been individual culture areas since Neolithic times. Only the Iberian peninsula was unaffected for a millennium. The history of the late Iron Age consists thus in the relations of a small number of widespread cultures with each other and with the rising power of Rome.

Celtic La Tène Culture.—In Britain the period corresponding to the continental late Iron Age is called early Iron Age A, B, C. During the 5th century B.C. southeastern Britain was occupied by Celts from the continent. This Iron Age A phase continues into the 4th century B.C., overlapping the Iron Age B of the southwest, which produced the Glastonbury pottery. The Iron Age C culture begins with the invasion of the Belgae into Kent in 75 B.C. The Celticization of Ireland may have begun during the 2nd century B.C., bringing the Goidelic strain to the island. (*See* also LA TÈNE.)

Germanic Culture of the Northern Early Iron Age.—During Montelius phase VI the northern late Bronze Age culture spread as far as the middle Rhine, Main and Sudeten mountains, where in the 4th century B.C. it was isolated by the Celts from its northern connections. Little iron was used, and local differences are clearer than chronological ones. Hanover, Schleswig-Holstein and Denmark form the richest zone, being close to the La Tène area. Norway and Sweden are comparatively poor. The Germans were passive toward the Celts in the 4th and 3rd centuries B.C., but during the 2nd they themselves began to move. The Cimbri and Teutons during the later 2nd century B.C. advanced southward from Jutland (113 B.C., battle of Noreia), followed by the Vandals, then the Burgundians and in the late 1st century B.C. the Goths. The Germanic tribes advanced during the 3rd to 1st centuries B.C. in central Germany and Bohemia, in southwestern Germany (Vangiones, Triboci-Nemetes) and western Germany (Chauci, Frisii, Langobardi, Angrivarii, Cherusci, Chatti, Main-Suebi), where they became strongly Celticized. The resulting wars, described by Caesar, made the Germans neighbours of the Roman empire. During these wars in the last century B.C. much Celtic loot fell into Germanic hands; *e.g.*, the silver cauldron from Gundestrup, Denmark, and the chariot from Dejbjerg.

Rhaeto-Illyrian Culture of Alpine Tradition.—In the central Alps the culture of the Urn Field Age continued, enriched by influences from the various early Iron Age cultures. There are local subgroups of the culture: Bellinzona (Ticino), the Melaun-Fritzens (Grisons, Lichtenstein, Vorarlberg and the Tirol) and the east Noric group (Styria, Carinthia). The first group shows affinities with the Certosa period and the second with the Hallstatt Illyrians, while the third is a direct continuation of the native Hallstatt culture. We know from written sources that the Illyrians contributed racially to forming the Rhaetians. The Alpine traditionalism remained influential in Grisons.

The Iberian Culture.—Celtic movements of the 4th century B.C. penetrated Spain from France as far as the Sierra Morena; beyond, the population established there from Neolithic times remained undisturbed. Avienus, writing in the 4th century A.D., first writes of the Iberians and gives their tribal names. The culture begins in the 6th century B.C. and ends with the Roman penetration of the 2nd century B.C. There had early been trade with Greece and Carthage, stimulating imitation; *e.g.*, in pottery, with its stylized figural decoration, with many local variations. Figural sculpture also was influenced by Greek art; *e.g.*, the Lady of Elche. The main cultural centres are on the coast; the interior may have retained the older culture into the Roman period. (RD. P.)

IX. INDIAN SUBCONTINENT

After the Paleolithic assemblages of stone tools there is little evidence of human cultures in the Indian subcontinent until the establishment of agricultural communities in Baluchistan and northwest India, probably in the 4th millennium B.C. though perhaps earlier. Thereafter the rise of the Indus civilization shows the existence of a bronze-using urban economy of a type familiar throughout the ancient orient from the early 3rd millennium B.C.

The Indus Civilization.—By about the middle of the 3rd millennium B.C. there had been established in northwestern India a Bronze Age civilization, urban and literate, over a tract of country 1,000 mi. long and comprising mainly the valleys of the Indus, Sutlej and Ravi rivers. In some sense this Indus civilization must be related to the village cultures of Baluchistan and Sind, but there is a sudden transition from simple, self-sufficient hamlets and townships to a complex system of unified government expressed in stereotyped pottery forms, the use of kiln-fired bricks, a consistent series of weights and measures and a formal script throughout the area. Sixty or more sites are known, ranging from villages to towns and including two major cities, Harappa in the Punjab and Mohenjo-Daro, 350 mi. S. down the Indus, in Sind.

While this civilization shares in its basic technology features in common with the other contemporary urban cultures of the ancient orient, it has a strongly marked individuality and seems on the whole to have had little contact by trade or diplomacy with its nearest neighbours in Elam and Mesopotamia. Dating is therefore not easy, but in the mature form in which we know it the Indus civilization was certainly flourishing in the time of Sargon of Akkad, and lasted virtually unchanged for another millennium, when it appears to have been brought to a violent end by the Aryan invasions. The static quality of its material culture is very marked, showing as it does no essential changes from beginning to end of the available stratigraphic series.

The bulk of our information comes from three sites, Harappa, Mohenjo-Daro and Chanhu-Daro, of which the second has the best-preserved layout. At Harappa traces of an earlier settlement, with pottery of Zhob valley type, were found below the citadel defenses; at Mohenjo-Daro and Chanhu-Daro the earliest levels are inaccessible beneath the present water table. The village sites of Amri and Lohri in Sind showed an Indus civilization settlement in each case overlying one using the painted buff ware of Amri type. At Chanhu-Daro, two phases of secondary occupation were identified over the Indus culture ruins; of these, the so-called Jhukar culture may have some western affiliations in its bronze types (shaft-hole ax and pins), and is referred to again below. At Harappa, the last phase, again later than the Indus civilization, is represented by a cemetery (Cemetery H) and some occupation scatter, with distinctive, painted black-on-red pottery of uncertain origin. The not altogether typical site of Rupar in the Himalayan foothills has a settlement with painted gray ware, also referred to below, overlying the Indus phase.

The two major cities, Harappa and Mohenjo-Daro, may, in the absence of any other sites of comparable size yet discovered, be taken as twin capitals. Their material culture is identical, and although the site of Harappa has been much robbed, enough remains to imply that the city had a plan closely similar to that of the better-preserved Mohenjo-Daro. The layout appears to have consisted of a gridiron of building blocks separated by wide streets; there is some evidence for 12 such blocks forming a square city one mile across, oriented to the points of the compass, and with the central block on the west side occupied by a defended citadel set on a massive platform of mud brick faced with baked brickwork. At Harappa the defenses of the similar citadel have been partially excavated, showing the presence of angle towers, monumental gateways and terraced approach roads. The defenses themselves comprised a clay rampart and mud-brick wall bonded into a similarly constructed platform, and the outer face was revetted with a baked brick skin.

The lower town, explored in large areas at Mohenjo-Daro, consisted of courtyard houses set within the main blocks and separated by small irregular lanes. Bathrooms were common, and there were elaborate drainage systems communicating with main sewers in the streets. At both the cities blocks of what appear to be workmen's quarters of identical two-roomed units have been recognized, at Harappa associated with a series of circular corn-pounding platforms and a great granary; at Mohenjo-Daro the comparable granary was on the citadel itself. The brickwork was probably largely plastered, and the use of wood for upper stories is likely. The Mohenjo-Daro granary appears to have been mainly a timber construction above its massive podium.

The buildings on the Mohenjo-Daro citadel include a large bath with surrounding verandah, assembly halls and what look like collegiate or communal buildings as well as the granary. There is no recognizable palace or temple, and a priesthood with affinities to Hindu tradition has sometimes been inferred as the likely seat of authority.

The material culture of the Indus civilization includes a competent wheel-made pottery tradition, with some black-on-red painted pottery. Tools and weapons (spears) are of copper or bronze and are archaic in type, neither the shaft hole for axes nor the mid-rib for spears and knives being known. There are, however, good beaten bronze vessels and elaborate jewelry in gold and semiprecious stones. Faïence was made and there was a very high standard of seal engraving. Models in clay and bronze show that more than one type of wheeled cart was in use, drawn by oxen, as there is no evidence for the use of the ass or horse.

While there is no monumental art in the Indus civilization, a number of important pieces of sculpture in stone and castings in bronze show the existence of a vigorous and individual art style. Some stone sculpture seems to have had metal embellishments attached and to have been painted. There are a large number of figurines of women and animals in baked clay. The steatite stamp seals, usually square, are among the most characteristic works of art in the Indus civilization, engraved in an assured style of glyptic with animal or mythological figures.

These seals also afford the main source for the Indus civilization script. Nearly 400 signs exist, in a stiff hieroglyphic style, not however recognizably pictorial, and they presumably represent a syllabary. The language they denote is unknown, and the longest inscription contains only 17 signs; most of them have not more than half a dozen.

A carefully controlled system of weights and measures prevailed throughout the Indus civilization. The cubical stone weights fall into a system binary in the lower values (probably based on the traditional Indian ratio 16) and decimal in the higher, with fractional weights in third. Fragments of what appear to be scales indicate the existence of a decimally divided "foot" of 13.2 in. and of a "cubit" of about 20.7 in. Corroboration of the use of both these units comes from a large series of check measurements on buildings of the culture.

The basic agriculture on which the civilization relied is hinted at by finds of wheat, barley, peas and melon seeds in the cities, and a very important find of fragments of cotton cloth at Mohenjo-Daro indicates the antiquity of this fibre in India. Domestic animals include humped cattle, dogs, cats and buffalo, while the animals depicted on the seals imply a jungle and marsh fauna existing in conditions very different from those obtaining in the region today.

The main evidence for outside contacts is afforded by the seals of Indus type found in Mesopotamian sites. About 30 are known, and dated contexts range from *c.* 2500 to 1500 B.C., the majority being Sargonid. Other pieces of evidence include stone "house urns" (probably from the Makran) found in early Dynastic contexts in Sumer and at a low level in Mohenjo-Daro, and representations of humped bulls (presumably Indian) on early Dynastic objects at Tell Agrab.

Animal-headed and spiral-headed pins on Indus sites, and a shaft-tube ax-adz from Mohenjo-Daro, suggest imports or invasion from the west in the second half of the 2nd millennium B.C., and with this would go the metal types in the Jhukar levels at Chanhu-Daro already mentioned. It is difficult to associate these, however, with the Aryan invasions of the *Rigveda*, though they may represent some tentative precursors of this movement. The "H" cemetery at Harappa has sometimes been attributed to invaders from the west, but the red-on-black painted pottery, although distinctive in its ornamental repertory, is nearer to local traditions than to anything likely to have been brought from the northwest at this time. The massacred bodies in the houses and streets at Mohenjo-Daro, and much other evidence, indicate that this must have been the case, even if the civilization was somewhat on the wane by this time.

Post-Harappan India.—The end of the Indus civilization came

suddenly and apparently as the result of attack from the west. Precise dates cannot be given, but the centuries between 1500 and 1300 B.C. would represent a likely chronological setting for these events that brought the Indus civilization to an end. Direct archaeological evidence has not been obtained for the Sanskrit-speaking newcomers, but their material culture is reflected in the *Rigveda,* composed in the second half of the 2nd millennium B.C. and consisting of a group of hymns and religious poems. From this evidence it can be seen immediately that the archaeology of the Aryans in India must have been in accordance with other branches of Indo-European language speakers at that time: a semipastoral existence based on flocks and herds and above all the horse; the use of the war chariot; and a technology which did not include the use of iron. The effect of this barbarian economy upon the highly developed urban culture of the Indus civilization can only be guessed at, but such evidence as there is suggests that the city culture was largely submerged except in certain important contributions to religious thought and speculation.

The problems of the phases immediately following the Indus civilization in northern India engaged field workers and excavators there in the years immediately following World War II. It was shown that on at least one site of the Indus civilization (or, archaeologically speaking, the Harappa culture), that at Rupar, 60 mi. N. of Umballa, a settlement of people using a characteristic black-on-gray painted pottery follows upon that of the Harappa culture. This black-on-gray ware has furthermore been found on more than 20 sites between the rivers Sutlej and Ganges, including a dozen places mentioned in the ancient Indian epic the *Mahabharata,* usually supposed to have been composed late in the 2nd millennium B.C. and largely descriptive of events in the Doab, in which the majority of these sites lie.

At one of the most famous of these, Hastinapur near Meerut, excavation has shown that the earliest settlement on the site, overlaid by one using black-on-gray ware, was characterized by an ill-fired, thick, ochre-washed pottery, known also from two other sites in the same region, Rajpur Parsu and Bisauli. Both these sites have also produced hoards of copper tools including flat ax blades and barbed spearheads or harpoons (though not in conclusive association with the pottery); such hoards and single finds of analogous copper implements are found elsewhere in the Doab and extend into Bengal north of the rivers Narbada and Mahanadi.

It seems likely then that these copper hoards date from an immediately post-Harappa phase, probably overlapping with the stage in which the painted black-on-gray ware was in use, and that a date late in the 2nd millennium B.C. or early in the 1st would be appropriate. Whether any of these elements of material culture can be referred to the Aryans must of course remain a matter of conjecture.

Outside the restricted area of northwest India discussed above, evidence for post-Paleolithic man is very slender until the dawn of the historical period. Some of the flint industries of microlithic type and the pointed-butt stone axes may go back to the 2nd millennium B.C., but there is no direct evidence of their upper date, and their lower date, as will be seen, comes to a century or two before the Christian era. Such stone types occur on the whole in India south and east of the Vindhya hills and the Ganges.

The lower limit of the painted-gray-ware culture in northwest India is unknown, but the next archaeological phase that can be distinguished has the advantage of being linked with more than one historical event. At Taxila in the extreme northwest the earlier settlements in the Bhir mound must lie in the 4th century B.C. as they antedate the Greek imports on the site associated with the campaigns of Alexander, if not in an even earlier phase. House plans of about this time in the Bhir mound show buildings set round a courtyard and including a hall with a line of three central pillars. On the same site a very characteristic pottery type can be assigned to the pre-Alexandrian levels; it has a burnished, almost metallic black surface and has been named northern black polished ware. It can be shown that this type of pottery continued in use into the historical Mauryan period, to about 200 B.C., and it has been shown to have a distribution in India practically coextensive with the empire of Asoka, *c.* 274–232 B.C. The not very conclusive evidence from the Ahichhattra (Ramnager) excavations suggest that there at least northern black polished ware is later than the painted black-on-gray ware described above, but there is no evidence as to whether there was direct succession.

Mauryan archaeology is represented by the well-known sandstone pillars with the Asokan edicts (with carvings of the same period, these share a particularly highly polished surface); the well-known series of stupas, which at such sites as Sanchi show clearly the derivation of the type from a burial mound with surrounding timber fence; small circular temples such as that at Bairat in Rajasthan; and rock-cut caves reproducing architectural forms. The great fortified site of Old Rajgir, which has been attributed to the 5th or 6th century B.C., has been shown by excavation to begin its existence at a time when northern black polished ware was in use at least, though this need not mean a pre-Mauryan date.

The best-known archaeological evidence of the Mauryans is the inadequately excavated and recorded site of the capital city of Pataliputra (Patna). Extensive remains of the timberwork defenses recorded by the Greek envoy Megasthenes were found, however, as well as the timber substructures of what was interpreted as a ceremonial hall of Achaemenian type with polished stone columns. Later excavations suggested that this interpretation of the remains should be treated with reserve, but the stone polishing together with the type of the pillar capitals show that in the 3rd century B.C. there must have been powerful Iranian influences on Mauryan art and architecture.

Outside northwest India and the boundaries of the Mauryan empire under Asoka little is known of the archaeology of the late 1st millennium B.C. Work at Brahmagiri in Mysore State, however, has given a partial sequence in that region, running back from the historical Andhra dynasty of the mid-1st century B.C. to an approximate date early in the 1st millennium B.C. The sequence can be divided into two pre-Andhra phases, of which the first is a basically stone-using culture, but one importing or making a few objects of copper and still more rarely of bronze. The stone industry includes pointed-butt stone axes and microliths of types mentioned above, and is accompanied by a coarse, hand-made pottery. There is slight evidence of rectilinear timber-framed houses, and burial was by inhumation.

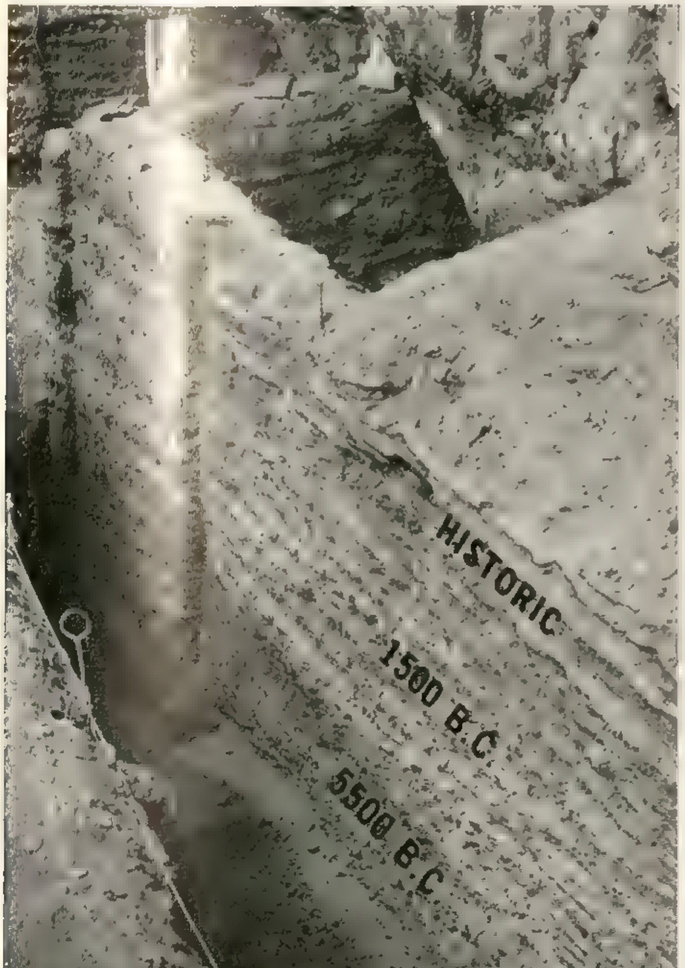
This phase was succeeded by an intrusive, iron-using culture having no affinities to that which preceded it. The iron equipment of these people includes sickles, swords, spears, knives, arrowheads and wedges, and they have a distinctive "black-topped" red pottery. Timber buildings seem to have been used.

The most striking feature of this phase is the great series of elaborate megalithic burials, some within stone cists of types widely distributed in peninsular India between 10° and 18° N. lat. The relationship of such tombs to the chambered collective tombs of Europe is quite uncertain, and they may well be the result of an independent evolution from a simple pit grave with slab lining. The Brahmagiri tombs were of two types, both set within circular walled structures; in one type there was a central pit in which the body appears to have been laid on a bier with its grave goods and left to decay, selected bones later being transferred elsewhere; in the other the burials were made in stone cists, on occasion with a porthole entrance through one side. The burials were fractional, with up to six skulls present in one tomb, and grave goods included iron tools and weapons and pots ranging in number from 6 to 62 in the ten excavated tombs of this type.

In the town site at Brahmagiri adjacent to the cist graves just described, the culture corresponding to that represented by the grave goods in the tombs could be stratigraphically placed earlier than a settlement of the Andhra culture, itself dated by Roman coins to the middle 1st century B.C. The iron-using megalithic culture, intrusive to the area, would then fall into the two centuries before that date, and historical probabilities would suggest that it was a reflection of folk movements in the disturbed years following the death of Asoka about 232 B.C.

In the northwestern part of the peninsula archaeological material such as that at Taxila in the Sirkap site can be dated in reference to Indo-Greek historical connections through the Saka dynasties of the 1st century B.C. into Indo-Parthian and Kushan

Step-trench excavation of Tell Judeidah, an ancient city of Syria. The tell (mound) of debris grew from the sixth millennium B.C. to the early Christian era. Buildings, largely of mud brick, slowly crumbled, collecting within and around the bases of the walls. The debris preserved the bases of the walls and added to the height of the ground level. On top of this layer, other buildings were built and the process was repeated. Some layers do not extend all the way across the mound



TWO KINDS OF STRATIGRAPHY

Both sites were inhabited during several millennia, and debris has been deposited in layers. Layer interfaces do not necessarily correspond to boundaries between cultural phases

Trench excavated in the floor of Veratic cave near Birch Creek, Idaho. A rock shelter, not a true cave, it was occupied by Indian food collectors who camped briefly, leaving artifacts. Detritus eroded from nearby cliffs to cover these remains. Other groups camped on top of the layer, and the process was repeated. The layers in the walls of the trench suggest climatic conditions under which they were deposited, and permit inferences about man's environment. Three major climatic phases and several cultural phases, spanning nearly 10,000 years, are represented

Partly occupied Indian pueblo at Old Oraibi, Ariz.; buildings to the right are abandoned. If this village now were abandoned entirely, a tell-like layer of noncontemporaneous remains would result. On excavation, the buildings could not all be expected to belong to the same period of occupation

CHRONOLOGICAL INFERENCES FROM MAN-MADE REMAINS

South end of the temple of the goddess Innanna (Ishtar) at Nippur, Iraq, showing remains of two shrines. The walls are from the ninth (now labeled VII) of 24 levels, indicating their relative date. Architectural style and objects found inside were compared with similar objects from other sites with known dates, and the cultural phases are identified as Early Dynastic II/III

Great plaza and pyramidal mound supporting Temple I at Tikal, one of the largest Mayan centres in Guatemala. Unlike Egyptian pyramids, this mound was built for the temple, as well as for burials. An earlier pyramid was later encased inside a larger one, forming inner and outer layers. Chronology is inferred from layering, architectural style, inscriptions and the contents of Late Classic and Post-Classic burials

Hut in the Paleolithic settlement at Doení Věstonice, Czech., with an oven containing remains of more than 2,300 clay parts of animal figurines. The presence of these earliest-known ceramics in only one hut indicates that special loci of production already existed

Grave Circle A and shaft graves at Mycenae, Greece, that yielded elaborately decorated treasure testifying to craft specialization and wealth of occupants. The stonework suggests experience with monumental architecture; and the exclusiveness imposed by the circuit wall indicates the burial ground of an elite. These imply a stratified society with occupational specialization, and large-scale architecture which is usually associated with urbanism

CULTURAL INFERENCES FROM MAN-MADE REMAINS

Mississippian ceremonial mound group at Etowah, near Cartersville, Ga., dated before European contact. Traces of a moat are visible behind the mounds; in the foreground is a plaza containing burials. The mortuary-temple mound in the left background now is completely excavated. Differences in content and orientation of the burials imply social differentiation. Accounts by early explorers from Europe suggest that the two mounds in the foreground may have supported houses of ceremonial leaders. The complexity of this centre and the absence of others in its vicinity suggest that it served more than the immediate area

Possible kill site at Isimila in Tanganyika. Negative evidence, absence of bones from the extremities and skull, suggests that the *Hippopotamus amphibius* may have been slaughtered or scavenged by men; other predators rarely are as selective. Absence of other human traces may indicate that the location was functionally specific, that only one subsistence activity was carried out here. Tools from elsewhere in same horizon identify the feature as Lower Paleolithic, late Acheulian

Grave of a bear from a dwelling site at Sorviken near Storuman, Sweden. The axecleft skull and the bones, cracked as if for marrow, imply that men ate the animal. Religious practices are implied by the ritual arrangement of the bones with the head to the north, and the covering of branches and birch bark. Other artifacts and their present-day counterparts link the site to Lapp culture

Paleolithic open air site at Ambrona, Spain, with bones of extinct straight-tusked elephants. Positive evidence, stone tools and traces of fire may indicate human activity beyond that of a functionally specific site

CULTURAL INFERENCES FROM ANIMAL REMAINS

times. In the southeast, however, fixed points for dating the native cultures were lacking until the identification and excavation of a Roman trading station at Arikamedu on the Coromandel Coast. The site, which may be the Podouke of the *Periplus maris erythraei*, yielded imported Arretine and other Mediterranean pottery of the 1st centuries B.C.–A.D., together with gems and glass, and had a considerable area of brick-built structures, some of which may well have been warehouses. A characteristic type of native pottery on the site has rouletted patterns derived from the imported Arretine wares, and this constitutes a secondary dating point which has been used on other sites such as Brahmagiri; it occurs also at the town site adjacent to the well-known Amaravati stupas and elsewhere in eastern India.

At one such site, Sisupalgarh, near Bhuvaneswar in Orissa, it was possible to utilize the Arikamedu and Brahmagiri dating evidence to good effect on a city site which continued in occupation until the middle of the 4th century A.D. The material culture represented on the site appears to have been uniform throughout its history, with imported pottery of the Brahmagiri megalithic culture appearing in the early (but not the earliest) phase and rouletted Arikamedu ware at a later stage. The culture appears to have been iron-using throughout, with timber and brick buildings and later stone constructions of laterite blocks. Early in the middle period (beginning of the 2nd century B.C.) the city was enclosed in defenses which form a square with a side ¾ mi. long; the rampart was originally of clay but was faced with burnt brick revetments in the early 1st century A.D.

The great series of excavations at Taxila take one into the world of Greek and Parthian contacts; the Sirkap site was occupied from the middle of the 2nd century B.C. and was defended by bastioned stone walls almost from the first. In its second period, ending about A.D. 150, Roman imports of glass and bronzes were reaching northwest India.

Elsewhere the application of archaeological method to the later phases of Indian history has hardly begun. Studies of sculpture on art-historical lines have been carried out, but no secure series of types dated from excavations has been produced. A beginning has been made at Ahichhattra, near Bareilly, where a stratified sequence of pottery and figurine types has been obtained and correlated, stretching over nine main phases between before 300 B.C. and A.D. 1100. This city site was continuously occupied and constantly rebuilt during this period; houses were built of burnt bricks, and there were two remarkable terraced temples, square in plan, one of which was dated as early Gupta (4th century A.D.).

Apart from some architectural studies, archaeology has been used in Islamic contexts only in the small-scale excavations at Adilabad, a fort of the Tughlakabad complex at Delhi, occupied and constructed around A.D. 1325.

BIBLIOGRAPHY.—The earlier Taxila excavations were published by Sir John Marshall, *Taxila* (1953); the remaining sites discussed in this section are published in the journal *Ancient India*, nos. 1–7 (1946–53); Stuart Piggott, *Prehistoric India to 1000 B.C.* (1950); Sir Mortimer Wheeler, *The Indus Civilisation*, supp. vol., *Cambridge History of India* (1953). X. CHINA, SOUTHEAST ASIA AND JAPAN

Gobi Cultures.—At the beginning of the Holocene, when the waters of retreating glaciers gave the finishing touches to the loess-covered landscape, north China appears to have been uninviting as a habitat for man. No traces of human activities bridge the gap between the late Paleolithic industry of the Upper cave at Chou-k'ou-tien and the Yangshao villages of the late Neolithic. In other words, in place of a Mesolithic or early Neolithic there is a hiatus. In Mongolia, however, finds pertaining to those phases were made in abundance. Deposits of microlithic industries around ancient lake beds tell of a flourishing life of hunters and, later, primitive husbandmen in lands that have since turned into deserts in the slow process of desiccation which made the Gobi grow and the Chinese swamplands shrink. The best-explored station of the Gobi culture is Shabarakh-Usu (44° N., 104° E.). Their lithic inventory links these cultures with the expanded front of post-Paleolithic microlith-using cultures in the west, such as the Capsian of north Africa and the Natufian of Palestine, though possibly with a time lag. Even so, Pierre Teilhard de Chardin considers a date as early as 8000 to 10,000 B.C. for the beginning of Shabarakh. Comparable strains appear in Jehol (Ulan Hata; Lin-hsi) and north Manchuria (Hailar and Ch'i-ch'i-ha-erh [Tsitsihar] regions), where Siberian influences are predominant. It is noteworthy that these industries of small chipped blades and scrapers and polygonal nuclei (micronuclei) are not found to the south of the line where later was erected the gigantic structure of the Great Wall, which thus marks a cultural border line of surprising stability.

Painted Pottery Cultures of North China.—The Neolithic hiatus came to an end when, unheralded by archaic forerunners, a splendid late Neolithic culture with painted pottery spread rapidly across north China. First discovered by J. G. Andersson at Yang-shao-ts'un (west Honan) in 1921, this still insufficiently explored complex is often termed "Yangshao culture." Its upholders were settled farmers who were living in fairly large villages on the fertile and sparsely forested loess soil along the rivers of Kansu and the adjacent provinces to the east as far as Honan. Sometimes they chose steep terraces that were easily defensible and well above the flood plains. Their staple crop was millet, but rice too was cultivated, at least in Honan. Pits dug in the loess served as dwellings and storage holes; in Kansu, walls with a plaster finish have been observed. The existence of timber huts can be surmised. The implements were made of polished stone; no chipped tools occur. Heavy axes with a rounded rectangular cross section, flat axes, adzes and knives of trapezium and semilunar shapes with two perforations are the commonest types. Beautiful minerals such as turquoise, jade, amazonite and marble were worked into pendants and beads, and jade, imported from east Turkistan or Siberia, was cut into slabs and perforated with hollow drills. Jade disks similar to those used by the Chou princes in ceremonial and worship were recovered from burials in the Pan-shan hills in Kansu.

The hitherto known phases of the Painted Pottery culture are named after type sites in Kansu, the only region where such phases have been recognized. The following styles appear as a clear sequence: Pan-shan, Ma-ch'ang, Hsin-tien and Sha-ching. There is no stratigraphic evidence of this sequence from any one site, but in a locality at Hsin-tien a layer of Hsin-tien remains was found to overlie a Yangshao stratum. No metal was observed in the Pan-shan and Ma-ch'ang sites, whereas both Hsin-tien and Sha-ching have yielded small bronze objects. This circumstance indicates a chronological relationship which is suggested also by the ceramic styles. Ma-ch'ang can be shown to have evolved from the Pan-shan style, the leading motif of which is the spiral or rotary S curve. Characteristic of the Ma-ch'ang style are angular ornaments such as meanders and T hooks. Transitional designs are numerous. Hsin-tien retains the meander in its narrow repertory of ornaments, but the shapes of the vases have undergone changes that point to some break in traditions. Sha-ching offers the aspect of an impoverished Hsin-tien style.

However, developments in Kansu localities not mentioned so far appear to have taken a somewhat different course. Patterns in black, executed with sweep and temperament, peculiarly conventionalized systems of curves derived from the spiral motif, are typical of the wares found in several dwelling sites such as Ma-chia-yao, Lo-han-t'ang and Chu-chia-chai. Comparable ornaments recur in tripods of the Ssu-wa-shan group, a cruder and most often unpainted ware which appears to have come from eastern China presumably some time after Ma-ch'ang. Some of these conventionalized patterns occur also in south Kansu, side by side with impressive flowerlike designs which are nearly identically found in specimens from Ching-ts'un and Hsi-yin-ts'un (southwest Shansi). These "flower" patterns are safe links between Kansu and the Shansi-Honan nexus and provide a dependable basis for chronological equations.

Hsi-yin-ts'un is a large dwelling site where small-scale excavations were carried out by P. L. Yüan and Li Chi in 1926. In contrast with Kansu, the painted wares there are associated with a burnished black ware which in the upper strata increases at the expense of the painted ware. The same mixture of painted and

black potteries—which are outnumbered by coarser types in grayish and brownish hues—obtains also at Yang-shao-ts'un (west Honan). Several west Honan sites, however, have the lustrous black or gray wares but no painted pottery at all. Excavations conducted by teams of the Academia Sinica in north Honan in the 1930s repeatedly resulted in the observation of red-black-gray sequences in this stratigraphic order, with gray usually referring to the Shang dynasty horizon. Finally, in the easternmost provinces (Shantung, Anhwei, Kiangsu, Chekiang) black alone is encountered. This distribution is highly significant. It clearly points to Kansu as the radiating hearth of the painted pottery in China. The ultimate sources of the art of vase painting will, however, be found in the near east and secondary centres in southeast Europe (Ukraine, Balkans), which latter offer the closest parallels to China.

Northern Frontier Sites.—Along the border line of the (chipped) microliths and (polished) neoliths referred to above, a number of sites between Lake Koko-nor and Jehol have been observed which testify to northern advances of the Painted Pottery culture. The most important of these sites in Ulan Hata (Chinese: Ch'ih-feng) in Jehol, where the painted ceramics enter an environment which theretofore was essentially similar to the Linhsi facies of the Gobi cultures. Farthest east, the strange ossuary of the Sha-kuo-t'un cave (between Mukden and Shan-hai-kuan) marks the easternmost extension of painted pottery, which there again is associated with elements of northern derivation.

Black Pottery Culture.—The typical pottery of this complex, which is also termed Lungshan culture (from an eponymic site in west Shantung), is black, lustrous, often surprisingly thin; wheel-thrown, the vases are distinguished by sharp, angular silhouettes; their surfaces occasionally show some incised geometric ornament and are never painted. Nor have painted ceramics of Yangshao type been encountered in any of the numerous sites located from Shantung down to Hangchow bay. Gray, brown, yellowish and whitish pots occur with the black wares. Implements are made of polished stone, shell, bone and antler and are largely similar to those from Yangshao. Metal objects are extremely scarce; a few arrowheads of bronze were unearthed in southwest Shantung. Excavations at Ch'eng-tzu-yai (Lungshan) revealed a lower stratum without metal, separated by a sterile sandy layer from an upper stratum which corresponds to a settlement abandoned apparently some time in the Western Chou period (1027–771 B.C.). While the early Yangshao farmers had domesticated chiefly the pig and the dog, and later had also cattle and sheep, those of Lungshan I had acquired the horse. To consider this complex as developed from the Painted Pottery culture entails serious difficulties; rather it may be assumed that new contacts with western Asia, particularly northern Persia (Tepe Hissar) and the east Caspian steppe (Shah Tepe), two areas offering conspicuous analogies, contributed to its formation. China would thus be linked with that widely spread ceramic fashion of black and gray burnished wares which in the old world supervened almost universally after the painted pottery and which appears as basically one and the same manifestation under varying names such as Aunjetitz (central Europe), Minyan (Aegean), Jhangar (Sind). In any case, the western analogies make it unlikely that the Lungshan culture in eastern China goes back beyond the beginnings of the 2nd millennium B.C., whereas its end may have been precipitated by the rise of the Shang dynasty around the middle of the 2nd millennium.

The southernmost Black Pottery culture station known is Liang-chu (Chekiang). At that site were found stone tools of apparently southern character (ridged adz; stepped adz) as well as pottery types strikingly reminiscent of west Asian ones (footed bowls), which in China have their parallels not only in Lungshan (Shantung) but also in the province of Szechwan, a circumstance which makes it all the more puzzling that this type of bowl with its characteristic long, hollow stem has not been reported from Kansu.

Whereas no trace of a script has come to light in Lungshan sites, there are several features to connect this culture with the Shang dynasty: shapes of Shang gray pottery and Shang bronzes of archaic type; tamped earth structures; and the use of animal bones, specifically shoulder blades, for the purpose of divination.

Bronze Age in Northern China.—Compared to western Asia, bronze appeared rather late in China. The oldest Bronze Age site known is that of the last capital of the Shang dynasty (*c.* 1523–1028 B.C.), located in an area of several villages west of Anyang (north Honan) and dating most probably from 1300–1028. The finds made there during 15 campaigns directed by Li Chi between 1928 and 1937 revealed a stage of metallurgy so highly advanced that the assumption of a more archaic phase became almost imperative. That phase would, naturally, correspond to the period of early Shang rule between *c.* 1523–1301, which is archaeologically still obscure. None of the earlier Shang residences, however, are identified, nor do we know of stray finds of truly primitive types of bronze tools or vessels. It seems, therefore, that the splendorous Shang civilization had emerged suddenly against the background of the Black Pottery culture, whose remains were found immediately underneath the Shang (or Yin) stratum in various localities of the Anyang area (Hsiao-t'un, Hou-kang, Kao-ching-t'ai-tzu, T'ung-lo-chai). This stratigraphic relationship, on which the calculations of the absolute age of China's prehistoric cultures depend, suggests the first half of the 2nd millennium B.C. for Lungshan and the late 3rd millennium for early Yangshao, dates which are in agreement with those based on comparisons with west Asian or European analogies.

Numberless objects of exquisite workmanship in bronze, clay, marble, jade, turquoise, shell, bone and antler have come from lavishly equipped tombs of the Shang kings and noblemen at Hsiao-t'un and Hou-chia-chuang, reflecting some facets of their mentality and luxurious mode of life, the bellicose aspect of which is more fully revealed through burials of war chariots, harnessed horses, skeletons of immolated prisoners and a great variety of weapons (without the sword). Historically important are the finds of scores of oracle bones and tortoise shells with incised texts relating to warfare and hunt, sacrifices to the royal ancestors, crops and herds, the weather and everyday events. They are written in a script which differs only paleographically from the Chinese ideograms still in use; it is a fully developed script, the origins of which are unknown. The same might be said of Shang art another unmistakable manifestation of Chinese genius: neither its sources nor its evolution are fully understood In contrast with the Neolithic past, which appears only as part and parcel of developments spreading all across Eurasia, something *sui generis* and specifically Chinese came to life in Shang art which profoundly affected the future course of Chinese art.

Southern China.—Scanty evidence of a Paleolithic in the Yangtze valley is followed by an archaeological void. Intense searching in no fewer than 367 caves along the Yangtze gorges (N. C. Nelson, 1926) yielded not one object of an archaic Neolithic character. In the deep south, the "Mesolithic of the Kwangsi caves" appeared some time during the obscure period of millenniums preceding the Neolithic. A crude pebble industry without flakes, blades, polished tools or pottery, the Kwangsi Mesolithic closely resembles the Hoabinhian of Tongking and probably was an offshoot of the latter rather than a locally rooted culture. The remains were collected from hardened layers overlying Pleistocene yellow clays. Without traces of subsequent developments, this culture disappeared again in time to permit stalagmitic covers to form on top of the archaeological deposits.

In the area between Swatow and Hong Kong, late Neolithic remains were observed by J. Shellshear, D. J. Finn and R. Maglioni. On the basis of those finds, Maglioni proposed the following provisional sequence: Hoifung I (Sov) has the polished rounded ax (*Walzenbeil*) as its characteristic tool; its potteries consist of a cord-impressed ware similar to Indochinese types, a smooth-finished ware with incised, dotted or stamped geometric ornaments around the neck, and footed dishes showing traces of paint in red and white. Hoifung II (Sak) stone tools are partly polished axes, leaf-shaped arrowheads and stone bracelets. In addition to a coarse corded ware there is a finer one with foot rims and stamped décor. Some unassimilated ethnic groups living in south China may be descendants of the "Sak people." Hoifung III (Pat) denotes a Chalcolithic culture with the stepped adz (*Stufenbeil*) as its most typical tool. Locally quarried hardstones were used for

bracelets, beads, arrowheads, beautifully finished flat axes and lanceheads, as well as halberd blades which undoubtedly are related to the bronze *ko* of Shang and Chou times. Corded ware continued to be made. A better, thinner but not wheel-made ware distinguished by a net pattern in low relief is a feature paralleled in the Black Pottery complex of Shantung. This culture, with affinities to the north and across the sea (Philippines), was probably that of a seafaring folk that may have to be identified with the Yüeh people; modified by a gradual acquaintance with metallurgy, it persisted until the conquest of the south by Han Wu Ti's armies in 111 B.C.

Indochina.—In contrast with a rich fossil fauna, no trace of Pleistocene man or his artifacts has been found in this area. The earliest cultures known are those of the caverns and *abris* in limestone formations of Tongking and north Annam. Paleo-Mesolithic in character, according to M. Colani, they are comprised under the designations of Hoabinhian and Bacsonian. In the deposits of the numerous sites (Bacson massif, north Tongking, 45 sites; Hoabinh, south Tongking, 33; north Annam, 18; central Annam, 3) three stages have been recognized, which partly overlap. Large, crudely chipped implements, among which the Hoabinhian "short ax" stands out, are typical of Hoabinhian I. Hoabinhian II shows a tendency toward smaller sizes of stone tools. Grinding of the edges of otherwise raw or crudely worked pieces is an innovation which H. Mansuy regarded as a foreign contribution. The so-called Sumatra type of oval adz chipped on one side only was current in Hoabinhian II and in Bacsonian I. The tendency toward smallness is also displayed by the Hoabinhian III tools. Edge grinding remains a characteristic trait of the Bacsonian II phase, and it was practised apparently all along the coastal stretch down to Perak. In Bacsonian III the old types of chipped scrapers and oval adzes give way to more perfectly polished tools, and for the first time there appears pottery, some of which shows cord impression.

The only station in the open and close to the modern sea level is Da-but (Thanh-hoa, Annam), where a sequence of ten strata yielded lithic types primitive enough to be described as eoliths, yet associated with pottery. The typical Bacsonio-Hoabinhian stations are never encountered in the alluvial lands occupied by the rice-growing Annamites.

Craniological remains of the early phases revealed two distinct elements, viz., a Melanesid one (Pho-binh-gia type) of Papuan-Melanesian affinities, in stations closer to the coast, and a Veddid one (Dong-thuoc type), of Indonesian-Malayan affinities, encountered farther inland. A third component points to paleo-Mongolid advances from China toward the late Bacsonian. Negrito traits were recognized by E. Patte in a child's skull from the late Neolithic site of Minh-cam (Quang-binh, Annam).

Late Neolithic assemblages are best known from settlements in the alluvial regions along the lower Mekong (Somrong-Sen; Mlu-prei) in Cambodia and at the upper Mekong (Luang-Prabang) in Upper Laos. From among a great variety of perfectly shaped and polished stone tools, the shouldered adzes—still absent in the archaic Neolithic of Da-but—stand out as most typical. Occurring in many transitional forms, their distribution coincides, as shown by R. von Heine-Geldern, with that of the Austroasiatic peoples in India (Munda) and farther India (Mon-Khmer), whereas they are sparsely represented in China and Japan and are absent in Indonesia. Some ceramics of this period have incised spiral designs which recall the painted spirals of Kansu (northwest China). Bronze objects appear before the end of these settlements, especially socketed celts derived from Yünnan types, the ultimate prototypes of which are Siberian and European.

The bronze culture of Dong-son (Thanh-hoa, Annam) is dependent on China and may have to be connected with movements of the Yüeh (southern Chinese: Viet) into Tongking and Annam before the middle of the 1st millennium B.C. A puzzling aspect of the Dong-son bronzes is their closeness to Hallstatt.

Philippine Islands.—Having been linked to south China and Formosa in the north, to Malaysia, the Sunda shelf and Borneo in the southwest and to Celebes in the south by land bridges in Pleistocene times, the Philippines reflect the early cultural stages of the continent and at the same time functioned as one of the major gateways to the Pacific islands.

The oldest-known artifacts, found on Luzon and Mindanao in strata resembling the Trinil beds of Java, are considered to be of Middle Pleistocene age. Cleavers and hand axes of possibly Upper Pleistocene age have also been collected in Luzon. This island moreover is very rich in Mesolithic sites that have yielded chert and obsidian chipped tools of semimicrolithic cast in stratified deposits. Similar industries recur in the Sunda Islands. No human skeletal remains have been recovered from any station of these phases.

Heavy and crude implements of Hoabinhian type associated with osteological material identifiable as Melanesid in character point to connections with Indochina. So do roughly worked axes ground at the edge only, which H. O. Beyer equated with Bacsonian types from about 6000–4000 B.C.

The first Neolithic wave, supposedly entering by way of Formosa, brought the round ax to the Philippines, whence this type traveled on into the Pacific as far as New Zealand. The ridged and tanged adzes appear to have come the same way but were developed on special lines in Luzon, where there probably originated the Polynesian tool known as the Hawaiian tanged adz. Continental inventions such as the Hoifung III stepped adz, but another variant of these peculiarly articulated adz types, contributed also to the formation of the Philippine form of the stepped adz in the 1st millennium B.C. The shouldered celt, sparsely met with on Luzon and Celebes, agrees with the archaic Indochinese types and thus may have arrived before 2000 B.C. The final Neolithic phase is marked by the advent, perhaps over several routes, of rectangular and trapezoidal adzes made of beautifully polished hard rocks. Refined lithic techniques such as the sawing and drilling of hard minerals were known to the islanders in the last millennium B.C. Their basically Neolithic culture was not greatly altered by the possession of some bronze socketed celts and weapons which reflect continental developments before 1000 B.C.

Japan.—Archaeological research in Japan has resulted in a detailed knowledge of the distribution and types of prehistoric remains without having led, at least by the 1950s, to a clear overall picture. To some degree this is due to the fact that the critical areas and phases on the Asiatic mainland are insufficiently explored. A question of prime interest, that of a Japanese Paleolithic, has not been solved. In late Pleistocene and earlier Holocene times the country was connected with the continent by land bridges that would have enabled man to migrate. Yet undisputed Paleolithic relics are wanting; conceivably they did exist but vanished under the ocean when in geologically recent times the country sank to its present level. The isles thus formed—perhaps only after 5000 B.C. in G. J. Groot's estimate—come closest to the continent in the extreme northeast (Sakhalin) and in southwest Honshu and north Kyushu opposite the southern tip of Korea. These areas no doubt were the two gates through which the main streams of Neolithic immigrations must have passed, while a third one, Kyushu, stood open to seafaring peoples from the south.

Japanese Neolithic.—The position of the isles favoured early intrusions of Siberian elements. The importance and southward diffusion of the latter, whom we may broadly equate with the Europid Ainu component of Neolithic Japan, can still be gleaned from linguistic survivals. No language older than Ainu has left its traces in Japan, according to John Batchelor, who showed that Japanese geographical names of non-Japanese etymology are without exception Ainu in origin and that geographical names in Siberia can be explained by Ainu words. Siberian connections can also be proved archaeologically. Trim chipped tools of fine homogeneous rocks such as flint, obsidian, agate, chalcedony and the like, which by their technique and their shapes—polyhedral cores or nuclei, lamellar flakes, fine blades—are related to lithic traditions of the subarctic zone of north Asia, are excellently represented in the northeast (*e.g.*, in the Sumiyoshi site, Hakodate city, Hokkaido) but are scarce in southwest Japan. Their prototypes will be found among the shapely materials from the Angara and Baikal areas rather than in Manchuria and the Gobi, as suggested by H. Watanabe. The same holds true for much of the primitive

pottery. Vessels with pointed bottoms, wavy rims, decoration by shell impression and shell streaking, spatula grooving and lunular impressions have their counterparts in Siberia as early as the 3rd millennium B.C. (Ulan Khada, Angara). An important early site in Honshu, Tado (Yokosuka city), which in addition to shell-impressed pottery offered samples of fibre and cord impression, is closely related to Sumiyoshi. The term "Tado-Sumiyoshi" defines that archaic Neolithic culture which had spread over the whole of northeastern Japan.

The Mongolid (Tungid and north Sinid) strain of the prehistoric Japanese must, to a large extent, be attributed to arrivals from Korea by way of the Tsushima straits, attested to by finds of clay vessels with pointed bottoms and with roller-stamped décor such as were made at Sobata (north Kyushu). Derived from a Korean *Kamm-Keramik* complex, this ware, along with an associated lithic industry, is again related to the Gobi cultures and the northeast Asiatic sphere at large. Distinctly Chinese types such as tripods with hollow or solid feet, as well as derivatives of the painted and black potteries, are absent.

Japan's Neolithic stone implements are so varied as to cover nearly the whole range of types current on the continent, inclusive of southeast Asia. An assemblage of crudely chipped pebble tools found with pointed-bottom pots in the Kozanji shell mound (Hyogo prefecture, Inland sea) has its closest parallels in the Hoabinhian of Indochina.

The time of the first arrivals from the continent is far from being exactly determined. Dates prior to the subsidence of the land are precluded by the very location of the Neolithic sites, shell mounds, close to the present shore line. E. von Eickstedt holds that the isles were still unpopulated as late as the 4th or 3rd millenniums, an assumption which is not contradicted by the crude estimates permissible on archaeological grounds, namely, the Siberian and Gobi parallels, with time lags commensurate to the eastward transmissions.

Jomon Period.—A coherent story in Japan's prehistory begins with the Jomon culture, named after its major archaeological legacy, the Jomon (cord pattern) pottery. Apparently this culture arose in the Kwanto plain (central Honshu) from the contact and amalgamation of the ethnic forces which had moved in from the northeast and the southwest and were absorbed, according to T. Esaka, by an already present older *Homo japonicus*. It has to be admitted, however, that the intimated process of absorption is not proved archaeologically any more than anthropologically, whereas there seems to be little reason for doubting that Jomon man, whose physical characteristics are well known from many excavated (contracted) burials, entered into the ancestry of the Japanese and, more pronouncedly, of the Ainu. Jomon man's unique ceramic art, distinguished by vases of bold and sometimes fantastic shapes with cord-impression effects, curvilinear designs, as well as plastic ornaments of an exuberant and imposing aspect, has been studied intensely, with a stress on the Honshu finds.

The early Jomon period adds fibre-tempered pots with flat bottoms to the pointed-bottom types, and there appear polished axes (Sekiyama; Kurohama). A widespread pottery style, Moroiso, distinguished by relief decoration, overlaps with the following stage. Middle Jomon produced ceramic types with heavy relief décor and spiral designs (Otamadai; Katsuzaka). Grotesque clay figurines of females and stone batons of a probably phallic significance appear in this period, as do polished cylindrical axes and, in the northeast, also quadrangular ones. In the later Jomon period, finer, thin-walled vessels predominate, and contrasts of smooth and corded surfaces as well as incised patterns are typical modes of decoration (Ubayama; Horinouchi; Omori). It should be noted that the Horinouchi type is found all over Japan, as is the graceful Kamegaoka style of the subsequent final Jomon period. Stemmed arrowheads are considered a novelty of the later Jomon culture, which on the whole retained the pre-Neolithic aspect of the bygone phases but advanced toward community life on a village level, as indicated by the very large sites. In the final Jomon period (Kamegaoka; Shonohata; Angyo) remarkable innovations are seen in the economic sphere. Agriculture was now practised, and cattle had finally become known after many ages during which the dog had been the only domesticated animal. Urn burials are a significant new trait, as are such luxuries as lacquered cups and combs and tooth-shaped jade beads. In the ceramics of this period, openwork effects and the pedestaled bowl were introduced. Lasting on in northeast Japan, the Jomon culture came to an abrupt end when a superior culture that possessed the horse, metal and rice penetrated southwest Japan about the 1st century B.C.

Yayoi Period.—Ceramics of fine texture, reddish-brown colour and neat, wheel-thrown shapes, first discovered in a Tokyo street, Yayoi, are one of the archaeological records of the changes brought about by their makers, who came as conquerors and became the founders of Japan. They cremated their dead, but the few skeletons recovered show them to be of Tungid (Tungusic) affiliation. They had come from Korea and brought a short-lived Bronze Age into western Japan, where their bronze weapons and mirrors of Chinese type have been found. Some imported Han mirrors give a safe clue, for the first time, to absolute chronology. Advancing toward the Kwanto plain but not farther east, that bronze culture was soon superseded by an Iron Age, presumably under renewed influxes from Korea and possibly also from China. A hard, grayish ware, the Iwaibe pottery, is associated with iron objects in the dolmen burials of Yamato, centre of the consolidated power of the rising empire. Attractive figurines of warriors, women, animals, houses and ships—strikingly different from the uncouth Jomon idols—form part of the funerary gifts, as do iron weapons, armour, helmets and the familiar claw-shaped jewels (*magatama*). Jomon man, as far as he did not fuse with the Yamato people who from A.D. 400 onward maintained official relations with successive Chinese courts, was slowly pushed back to the northeast. By the end of the 1st millennium A.D., the region of Aomori and north Mutsu was all that he still held on Honshu.

XI. ISLAMIC ARCHAEOLOGY

The first branch of Islamic archaeology to arouse interest was numismatics. The earliest publications—monographs by G. J. Kehr—date from 1724 and 1725, and a number of catalogues of coin collections in Rome, Padua, Göttingen and Stockholm were brought out during the course of the 18th century. The early 19th century witnessed the valuable work of C. M. Frähn, and in the second half of the century catalogues of the great numismatic collections in London, St. Petersburg, Paris, Istanbul and Berlin were brought out, which still belong to the main tools in this field.

Romantic interest in Spain led in the first half of the 19th century to the publication of large volumes with elaborate plates on the Muslim architecture of that country (the earliest writer being James Cavanah Murphy in 1813). The first investigation of the Muslim architecture and crafts of Egypt was attributable to Napoleon's campaign. French scholars were commissioned to bring out a systematic survey of Egypt, including its art, which was published in the 19 volumes of the *Description de l'Egyp-*

(1809–28). Later in that century other investigations of the Muslim architecture of Egypt were undertaken by Pascal Coste (1839), J. Bourgoin (1873–92) and A. C. T. E. Prisse d'Avennes (1877); the main value of these publications lies in their plates. Iranian architecture was studied somewhat later by P. Coste and E. Flandin (1851–67) and Hommaire de Hell (1859). The first half of the 19th century also saw the first thorough investigations of Islamic art objects (J. T. Reinaud, 1828, and M. Lanci, 1840 and 1845–46).

Muslim archaeology in the narrower sense (that is, the exploration of the past through excavations) did not commence before the very end of the 19th century. In 1898 excavations at the Qal'at Bani Hammad, the 11th- and 12th-century capital of the Hammadites in Algeria, were started by P. Blanchet and, in 1908, continued by L. de Beylié. Although this was only a site of limited, provincial interest, the published results threw considerable light on north African architecture, especially of the secular type, and on pottery and wall decoration. Another palace site of western Islam, Madinat az-Zahra, the residence of the Omayyad caliphs of Córdova in the 10th century, was first explored by R. Velásquez Bosco, about 1910, and these excavations were still intermittently continuing in the 1960s. Many structures were cleared and the elaborate stucco decorations applied again to the inside wall surfaces, while a small museum on the spot gave further insight into the material culture revealed by the excavation.

Perhaps the most important and most systematic excavation was conducted by the German scholars F. Sarre and E. Herzfeld at Samarra on the Tigris (1911–13). The campaigns cleared only a small portion of this immense 9th-century capital of the Abbasid caliphs, but they nevertheless provided a large amount of information about the arts and the life in a centre of the Muslim world in one of the artistically most active periods (*i.e.*, only a few decades after Harun al-Rashid). In view of the short existence of Samarra the excavated objects could also be used as a convenient clue for the dating of related but undated material from other sites. Several publications on the pottery, glass, wall decorations and paintings, as well as on the history of the site, were published, but the deaths of the excavators prevented the final publication of the volumes on the architecture, which would have been specially significant.

The great archaeological past of Muslim Iran was probed more extensively only at two sites. At Susa, J. de Morgan had started excavations at the end of the 19th century, but he and his immediate successor were mainly interested in the prehistoric and Achaemenid levels; a systematic unraveling of the various layers from the 13th century down to the pre-Islamic town was later undertaken by R. Ghirshman. More important as a cultural centre than Susa was Nishapur in northeast Iran, where J. Upton, W. Hauser and C. K. Wilkinson, on behalf of the Metropolitan Museum of Art in New York city, dug up the 9th-, 10th- and 11th-century levels, which yielded large amounts of stucco decorations, pottery, glass, stone carvings, metal objects and even some wall paintings, now to be found in the New York and Tehran museums. The great importance of this work (which was stopped all too soon) has been generally recognized. Other phases of the archaeological past of the east Muslim world, in the urban centre of Termez (Tirmidh) and the feudal castles of Khwarizm (Khorezm, Khiva), have been successfully explored by Soviet scholars, especially by S. P. Tolstov, who brought out three volumes on his Khwarizmian excavations (1948 and 1952). Even before this Russian scholars had published books on the Muslim architecture of central Asia and the Caucasus and articles on the finds at Sarai Berke, the 14th-century capital of the Golden Horde on the Volga.

The period between World Wars I and II saw a great deal of archaeological activity in Syria and Palestine, especially with regard to the earliest Muslim period, that of the Omayyad caliphs and their surviving monuments dating from the first half of the 8th century. Perhaps the most successful of these campaigns was that of the desert castle of Qasr al-Heir al-Gharbi near Palmyra, where the French archaeologist Daniel Schlumberger discovered an astonishing amount of figural and ornamental stucco decorations and paintings (exhibited in the Damascus museum, where the façade of the castle was also reconstructed). After World War II, the same excavator, as head of the French archaeological mission in Afghanistan, discovered at Lashkar-i Bazar on the Helmund river the vast palaces of the Ghaznevid winter capital. These excavations were particularly illuminating for knowledge of 11th- and 12th-century secular architecture, wall decorations and paintings. Other important archaeological work was done at Wasit, south of Baghdad, on behalf of the directorate general of antiquities of Iraq, by the British Institute of Archaeology (under Seton Lloyd and D. S. Rice) at the castle and Great Mosque of Harran in southeast Anatolia, and finally by Marguerite van Berchem at the medieval town of Sedrata in southern Algeria, the refuge of the heretic Ibadites.

Minor excavations took place at Fostat, the early Muslim capital of Egypt; the early Islamic centre of Istakhr near Persepolis; at Rayy, one of the most important medieval centres of Iran; at Balis in Syria; at Old Delhi and at several other towns and sites. In other cases excavators had really aimed at earlier civilizations, but before getting there the Islamic levels had to be cleared and these Muslim finds have often been accounted for in the main reports (Miletus, Baalbek, Hamah, Antioch, Alisar Huyuk, etc.).

Since a great deal of archaeological work depends on epigraphical studies, the importance of this specialized field has been fully recognized, once it was put on a sound basis by the Swiss Max van Berchem (1863–1921). This scholar organized a series of systematic investigations of epigraphic-historical nature, entitled *Matériaux pour un Corpus inscriptionum arabicarum*, to which he himself contributed several volumes while an international group of scholars wrote others. Publication of this series began in 1909 and the work was still in progress in the 1950s. Starting in 1931 the Frenchman Gaston Wiet, in collaboration with E. Combe and J. Sauvaget and assisted by a large group of other scholars, brought out a chronological *Répertoire* of Arabic inscriptions which by the mid-1950s had progressed to the 13th volume and the year 1305. Similar systematic collections for Persian and Turkish inscriptions had not been made, however.

XII. MEDIEVAL ARCHAEOLOGY

Medieval archaeology may be defined as the study of the arts of Europe, especially western Europe, from the 6th to the 15th centuries. In the earliest phase, it is concerned with the reconstruction of culture from objects and monuments alike; on the European continent, this phase embraces the 6th, 7th and early 8th centuries (Merovingian in France, Visigothic in Spain), but in northern Europe it begins slightly later and extends into the 11th century (Saxon in England, Viking in Scandinavia, early Christian in Ireland). In the later phases (Carolingian, 8th–10th centuries; Romanesque, *c.* A.D. 1000–12th century; Gothic, 12th–15th centuries), unlike the archaeology of other periods and areas, it is primarily concerned with the study of monuments; this may be said to reflect the emphasis placed upon architecture by the middle ages. Medieval archaeology must be distinguished from the history of art in this respect. The historian of art seeks to determine the centres of artistic development and the relationships between them; he accounts for artistic conceptions and procedures and evaluates the aesthetic importance of the works of art. The archaeologist stops at complete documentation; he is concerned with the detailed examination of extant as well as destroyed monuments, with the authenticity of their parts and the dates of these parts and with the reconstitution of the original forms; he is also responsible for the formulation of a proper nomenclature for the various periods and styles of medieval art.

The history of medieval archaeology, as a scientific discipline, did not begin before the 19th century. Prior to this time, the study of medieval art was only one aspect of general antiquarian research; the works of B. Willis in England, A. Ponz and Eugenio Llaguno y Amírola in Spain, Ole Worm in Denmark and Bernard

de Montfaucon, A. L. Millin and Alexandre Lenoir in France treated the medieval period only as part of the total artistic heritage of each nation. In England, specific interest in the medieval period was evinced by Horatio Walpole, Thomas Gray and their circle around the middle of the 18th century, but it did not ripen into a field of study for nearly 30 years. J. Britton, J. Milner, G. D. Whittington, J. Bentham and others, from about 1800 on, studied medieval antiquities in detail, in both England and France. Attempts were made at this time to determine the origins of Gothic architecture and to isolate and name the successive periods of English Gothic in particular. J. Milner (1798) proposed the general term Pointed to distinguish English Gothic style from the Norman or Romanesque of the 11th and 12th centuries in Britain, and subdivided it into three main periods, those of the acute arch (*c.* 1150–*c.* 1300), the equilateral arch (*c.* 1300–after *c.* 1450) and the obtuse arch (*c.* 1450–*c.* 1550). In 1812 T. Rickman reordered and renamed the categories as Norman (1066–1189), Early English (to 1307), Decorated (to 1377) and Perpendicular (to the 16th century). Rickman's styles were accepted as standard until 1851, when E. Sharpe proposed the more flexible system of Norman (1066–1145), Transitional (to 1190), Lancet (to 1245), Geometrical (to 1315), Curvilinear (to 1360) and Rectilinear (to *c.* 1550). All three descriptive nomenclatures are drawn from the forms of English Gothic windows and tracery. The last codification was still current in England in the 1950s, although the dates of the phases were disputable. On the continent, the first important studies of medieval archaeology were immediately posterior to the Napoleonic domination. G. Moller (1815) and S. Boisserée (1823), in Germany, A. de Caumont (1824) in France and C. Amati (1825) and G. Cordero di San Quintino (1829) in Italy were academicians as well as antiquarians; their work paralleled the romantic movement in literature and the Gothic revival in architecture. As a result of this renewed interest in the middle ages, a large number of archaeological societies and national commissions for the conservation of artistic patrimonies were founded in the next two decades.

As in England a few years earlier, the 1820s and 1830s on the European continent produced the first important syntheses of medieval archaeology, with the description of the major styles and the first formulation of a nomenclature for the successive periods. J. B. L. G. Seroux d'Agincourt (1730–1814) had called the art of the 9th to 16th centuries Gothic. De Caumont (1824) distinguished between Romanesque and Gothic and subdivided each into three periods: Romanesque comprised Primitive (5th–10th centuries), Secondary (*c.* 1000–*c.* 1100) and Tertiary or Transitional to Gothic (12th century); Gothic comprised Primitive (1200–1300), Secondary (1300–1400) and Tertiary (15th century). For J. Quicherat (1851) and F. Kugler (1858), A.D. 1000 was the critical date for the start of the Romanesque style proper, although specific names for the earliest period were not formulated until the end of the century, when various styles such as Late Roman (to the 6th century), Merovingian in France (6th–8th centuries) and Visigothic in Spain (to 711) and Carolingian (8th–10th centuries) were isolated. In the 1840s the discipline of medieval archaeology was given a firmer scientific basis by Robert Willis (1800–75) in England and by E. E. Viollet-le-Duc (1814–79) in France. Willis was interested in the exact analysis of individual monuments. His report on the state of Hereford cathedral in 1841 is a model study of an edifice preparatory to its restoration; his *Architectural History of Canterbury Cathedral*, a work which remained the foundation for all studies of this edifice, appeared in 1845. Viollet-le-Duc was active primarily as a restorer; his *Dictionnaire raisonné de l'architecture française du XI^e^ au XVI^e^ siècle* (1854–68) is a compilation of evidence collected from monuments undergoing restoration and fitted into the historic framework of medieval architecture as it was then understood. The primary contribution of this work to archaeology was the formulation of the controversial precept that the forms of Gothic architecture were determined by their function. The position of Viollet-le-Duc with regard to the construction of this architecture, namely that the rib was an indispensable armature for the vault, was challenged only by G. Dehio and E. Gall in Germany; it was accepted in France until 1934, when P. Abraham vigorously asserted that the rib was structurally without function but important in the visual effects of the style. The *Dictionnaire* remains, nevertheless, a summation of the French contribution to medieval archaeology during the first half of the 19th century.

The last two decades of the century and the years preceding World War I produced the syntheses of archaeology upon which modern knowledge is largely based. C. Boito published a study of Italian medieval monuments (1880) and Dehio and G. von Bezold a corpus of medieval architecture in all of western Europe (1887–1901); at the same time, R. de Lasteyrie du Saillant gave a comprehensive course on medieval French archaeology in Paris. In France, Germany, Austria, England and Switzerland, and later in Sweden and Denmark, repertories and descriptions of monuments by province or canton were begun by state commissions and archaeological societies; some of these series were not yet complete in the mid-1950s. In the 1880s the Merovingian and Carolingian periods, named from the corresponding periods in French history, were assigned a permanent place in the field, and an endeavour was made to define their styles. Dehio and Bezold established different categories for Germany, where the Carolingian style was the direct source for the styles of the succeeding Ottonian, Salic and Hohenstaufic periods; they expanded the term Romanesque, which designates a single style in France and Spain in the 11th and 12th centuries, to include the architecture of the Carolingian period. Because of this, Romanesque still has two different meanings as it is applied to the Rhine valley and to the Atlantic states. In France, the Romanesque style, from De Caumont on, has been divided into regional groups or schools. By 1900, De Caumont's three phases of Gothic had been amplified and given descriptive names: Transitional (12th century), Classic or High Gothic (1195–*c.* 1240), Rayonnant (to *c.* 1370) and Flamboyant (to 16th century). Transition later proved to be an unsafe term methodologically: it is considered that the principles of Gothic structure (ribbed vault, point support and point abutment) were not developed from Romanesque (continuous support) but were opposed to the latter; hence there was no transition, properly speaking, from one to the other. In 1884 E. Lefèvre-Pontalis claimed that Gothic architecture began with the ribbed vaults of the small abbey of Morienval near Soissons (dated by him *c.* 1122). An international dispute ensued, in which A. St. Paul, Dehio and J. Bilson participated; in 1898 Bilson showed that the ribbed vaults of Durham cathedral, a Romanesque edifice, were nearly 30 years older and suggested that Gothic did not originate in a single monument but was the creation of the Île-de-France region and was based on a series of earlier experiments in the technique of structure and in visual effects. Bilson brought to the field the same precision and care as had R. Willis. Finally Camille Enlart published his *Manuel d'archéologie française* in 1902–16, and A. K. Porter his *Mediaeval Architecture* in 1909; each is a summation of medieval archaeology, the first of detailed evidence, the second of filiations and developments.

The period following World War I saw a double movement in the field. On the one hand, scholars began a more extensive examination of the evidence. J. Puig y Cadafalch (1928) isolated an entirely new category of monuments from the 10th and 11th centuries, which he termed the "first Romanesque art" because they seem preliminary to the main development of this style (*c.* 1050). Henri Focillon (1931) re-evaluated the origins of Romanesque sculpture in the early 11th century; a similar project of Focillon, who died in 1943, and a group of his students for the architecture of the year 1000 was nearing completion in the mid-1950s. R. A. S. Macalister (1928), A. K. Porter (1931) and F. Henry (1933) re-examined Irish culture and art in the early Christian and medieval periods; J. Roosval in Sweden, M. Mackeprang in Denmark and A. W. Clapham in England synthesized the results of medieval archaeology in their respective countries. On the other hand, excavation, which was incidental in the 19th century and regrettably unscientific in most cases even up to 1914, began to occupy archaeologists' attention. Sites such as Cluny, Lorsch, St. Denis and Agaune were systematically explored. The destruction caused by World War II facilitated and accelerated

this activity; both France and Germany later yielded important information for the medieval period, most of which was still unpublished in the mid-1950s and could not yet be brought to the stage of synthesis. The stratigraphic technique of excavation was adapted to medieval sites such as St. Martin at Angers, France (1929), and Corfe, Eng. (1950); these experiments were as yet so isolated in the 1950s that no important conclusions could be drawn from them. Similarly, excavations in the interiors of monuments are now kept open for future study, wherever possible, by the simple expedient of placing strips of reinforced concrete across them, to support the pavement (St. Denis, Lausanne, Trier, Bourges).

The second contribution of the 1820s to medieval archaeology was the conservation of monuments. Organized control virtually did not exist in the 18th century; even Bartolommeo Cardinal Pacca's decree of 1820, for the preservation of the artistic patrimony of the papal states, was limited in its effectiveness, since it was aimed mainly at preventing the destruction or exportation of works of art. The dilapidated state of certain monuments served as an excuse for French archaeologists, under the leadership of De Caumont, to unite in requesting governmental intervention (1825–30). A state agency was created in France in 1830, which became the model for similar agencies in other European nations (Belgium, 1835; Prussia, 1844; Austria, 1853; England, 1882; Italy, 1909; Spain, 1928). The function of these commissions was the repair and maintenance of historic monuments; it was subsequently expanded to include historic sites. In the 1930s European legislation on historic monuments was brought up to date in nearly every nation, with provisions defining the spheres of activity of the commissions and the legal aspects of expropriation sometimes necessary to conservation. Conservation in most cases entails restoration. The first edifice to be restored by a modern state commission was the Church of the Madeleine at Vézelay (1840), under the care of Viollet-le-Duc, who can be said to have dominated the 19th-century theory of restoration; his original aim was to restore in the style of the original, but his later work shows that he often added entirely new parts in such style. This approach has been severely criticized, since it renders the original form of the edifice obscure amid restored parts and additions. The most satisfactory theory of restoration, that replaced parts or added consolidations be made obvious and apparent, was accepted by a United Nations Educational, Scientific and Cultural organization board of experts in 1950.

Medieval archaeology includes the study of objects in collections and those recovered by excavation, such as coins, textiles and metal objects; but excavations specifically to recover objects have been made only for the early phases and in such sites as the tombs of the medieval kings at Santa Maria la Real de las Huelgas in Burgos, Spain (1944–45) and at Westminster abbey (1949). Discoveries important for the history of medieval pottery were being made in the 1950s in the Royal Commission on Historic Monuments excavations in England. The scientific analysis of objects was facilitated by the use of modern laboratory techniques, which, in the case of Merovingian metalwork and early Flemish paintings, sometimes provided firm documentation as to their nature and authenticity.

XIII. POST-PALEOLITHIC AFRICA

Africa is vast, with little known about its archaeology; a general pattern was beginning to emerge by the middle of the 20th century, although many more careful scientific excavations completed by definitive publication were required.

In Africa the investigator meets with particular difficulties: cultural influences may have come from afar; climatic change has resulted in the inaccessibility of areas which were important a score of centuries ago; and severe soil erosion has caused stratification to be practically nonexistent on occupation sites. There is one compensation, however: in certain out-of-the-way corners of Africa men are still living under conditions that have changed little since the end of the Paleolithic; and the answers to some riddles that occupation sites propound to the excavator may be found there.

The Paleolithic was everywhere followed by the Mesolithic, a period when man continued to use stone tools, mostly microlithic, and, while still in the hunting and gathering stage, depended less for his food supply on large mammals than on fish and mollusks. In Africa the evidence for the Mesolithic is still scanty, but man, although scarce, must have existed. In the lower Nile valley, sites have been examined only at Helwan and Kom Ombo. At the latitude of Khartoum, for a considerable distance to each side of the Nile, have been found sites of a Mesolithic culture in which large, well-fired, unburnished pots decorated with designs impressed with a fish spine to make them resemble baskets were made, and barbed bone harpoons were used for fishing. Arrows were mostly armed with stone lunates, and in general the microlithic industry shows relations with the Capsian (of northwest Africa) and the Wilton (of east central Africa). The fauna indicates a climate much wetter than the present. The upper Kenya Capsian with traces of similar pottery found at Gamble's cave probably represents the Mesolithic of Kenya. Its pottery also copies basketwork. And while it is impossible to say where pottery was invented, the discovery of a prepottery Neolithic in Asia, with the existence of modern mud-lined baskets among the Nilotes, the accidental burning of which could have led to the invention of pottery, suggests that pottery was possibly an African discovery.

Neolithic.—The Neolithic is a field in which archaeologists are likely to make important discoveries. The inventions which led to the rise of man above the savagery of the Old Stone Age were made gradually in different places, and probably over a long period. Some, such as the domestication of animals, took place more than once. In a famine, a wild animal will sell itself into slavery to man for the food that will preserve its life. Thus cattle and goats, while certainly domesticated in Asia, may have been independently domesticated in Africa too. African jackals may have provided one breed of domestic dog, while the donkey and the cat are African. The polishing of stone implements was probably a by-

product of the grinding of red ochre, in wide demand for its magic properties since the Paleolithic and extensively used in Africa in the Mesolithic and later. One result of the grinding of ochre was to polish the grindstone, and another, when the upper grindstone was used at an angle, was to develop a sharp edge which, produced accidentally, may have led to the idea of grinding the cutting edge of celts or other tools. Repeated pecking of the flat surfaces of the grindstones which became too smooth to grind ochre efficiently led to perforation of the stone and thus to the development of the disk macehead of the Nile valley. Archaeology must establish where and when celts were first ground; but the partly polished celts of the Fayum and Khartoum are probably the earliest forms of that tool known. The cultivation of wheat, barley and flax probably were Asiatic developments which first entered Africa through the Nile delta; but more investigation is required. N. I. Vavilov and others indicate Abyssinia as the centre of the *Triticum dicoccoides* group of wheat grass and think that the cultivation of one form of wheat may have originated there.

In Egypt civilization first reached its full development *c.* 3000 B.C., but though it passed through Copper and Bronze Ages and introduced copper tools to the Sudan, there is no evidence of either of these ages in the rest of Africa, where a transition from the Stone Age, generally still Mesolithic in type, directly to the Iron Age took place gradually during the last two millenniums, and in a few places had not yet taken place in the middle of the 20th century. In some localities, an intermediate state, when Neolithic forms were used, occurred (*e.g.*, the former Belgian Congo and Gold Coast), but elsewhere (*e.g.*, Kenya) polished stone celts seem so rare that they may have been comparatively late imports from the north.

It is only with reference to Egypt and the Sudan that archaeologists in Africa can date finds that precede the Arab and European opening up of Africa; and more investigation is required to ascertain the extent of the influence of ancient Egypt on the rest of Africa. When Egypt was virile and prosperous, its traders traveled far beyond its boundaries to procure objects in demand by Egyptians, and with them must have gone small trade goods such as beads; but continuous raiding for slaves probably left a no man's land on Egypt's southern frontier and so prevented its having a greater influence. Mining for gold and copper may have taken the Egyptians far into Africa, but several gold mines in the northern Sudan attributed to the pharaohs appear to date only from the middle ages. The Neolithic cultures of Kenya probably owe their stone bowls only indirectly to Egypt.

Some cultural influence of ancient Crete may yet be traced in north Africa.

Iron Age.—The Iron Age in Africa began in the 6th century B.C. at Meroë, where an Egyptian form of civilization slowly degenerated for almost 1,000 years, from 550 B.C. to A.D. 350; but for several centuries the process of iron smelting was kept secret, and it was not before the 2nd century A.D. that it began to spread in Africa. Lake Chad probably was a secondary centre of dispersion, from which the knowledge of ironworking spread west, southwest and southeast. Possibly with it went—at any rate to west Africa—the custom of making sculptured stone and terra-cotta likenesses of deceased persons or their heads. For it is to be noted that the earliest figurines from Nigeria (Nok) are associated with ironworking. Excavations near Lake Chad show a people with pottery of early type with a full Iron Age technology, with Indian carnelian beads and figurines suggesting Punic influence. In classical times civilizing influences probably reached west Africa mostly north of the Sahara through the Fezzan, the home of the Garamantes. The date of the famous bronze heads of Ife is problematical, but they may have been inspired by an imported Roman bronze of the 1st century A.D. Cultural influences also traveled as far as the horn of Africa down the Red sea; of which a Greek captain in the 1st century A.D. gives an account in the *Periplus maris erythraei*. Traveling overland in the uncharted interior, divided among xenophobic tribes, long closed the interior of Africa south of the Sahara to external influence. Along the east coast, Greek influence was succeeded by that of southern Arabia, and Axum (Aksum) took over control of African trade from Meroë in the 4th century A.D. The prosperity of Axum largely depended on trade between India and Rome; it is therefore natural that Axum should have been the gateway through which Indian influences entered Africa, among them the construction of rain-water reservoirs. Its well-known obelisks may also show Indian influence. It is possible that some of the African gold that reached Rome through Axum may have come from as far as Senegal by the trans-African route between the desert and the forest that linked west Africa with the Red sea. Certain sites, along the east coast with stone masonry and many-roomed houses probably show Axumite influence. Small trading stations stretching between Aidhab on the Egyptian frontier and Zanzibar, usually with small mosques built in coral rag, celadon and sgraffito ware, glass and rare coins, date from the 11th and 12th centuries A.D. In the 13th and 16th centuries there were a number of merchant towns, in the ruins of which shards of celadon and glass are characteristic. As far south as Somaliland, connections were with Egypt. Farther south, similar merchant cities were connected with Islamic India. Later east coast settlements down to the 19th century are to be dated by Chinese porcelain and other imports.

From the 15th century also begins at certain coastal sites evidence of the European opening up of Africa.

On many sites readily datable imports are nonexistent, and archaeologists therefore try to reconstruct the past from the study of rock pictures, domestic animals, tribal brands and property marks, styles of building and burial, irrigation, tools, weapons and beads.

Rock pictures are difficult to date. They are rarely associated with sites of a single culture. Subject matter may help by giving a *terminus a quo*; *e.g.*, extinct animals, horses, chariots, camels, firearms, etc. Superposition is difficult to establish, and typology based on style can be misleading; investigators are also sometimes deceived by ignorance of the native artist's culture or by his inaccuracy. Rock pictures, too, may not survive where exposed to the weather. Too much, therefore, must not be deduced from their absence when it is due only to natural causes. Lifelike representations of wild animals are usually early, especially when engraved. North of the Sahara the earliest human representations seem to be of Bushmanoid archers. After a lengthy period during which man's main concern was cattle, in parts of northwest Africa came representations of chariots, which began in classical times and went on into the following period when horsemen with round shields gave place to camelmen with round shields. Most representations of camelmen do not antedate the Arabs.

Tribal brands and property marks may reveal connections with the Berber script or even with Meroë or Egypt. The typology of tools and weapons is a field in which further study will help the archaeologist. Beads, too, repay study. Modern and mediaeval beads from Venice, Hebron or Gablonz (Jablonec nad Nisou) can be identified, and agate and carnelian beads from Cambay in India; or even ancient Egyptian beads, if found.

XIV. POST-PALEOLITHIC ASIA IN THE TERRITORIES OF THE U.S.S.R.

Post-Paleolithic archaeology of central and northern Asia is based chiefly on excavation work of the 20th century. At the beginning of the century it was almost unknown, except for stray finds and several sporadic excavations. At the end of the 19th

century interest was stimulated by linguists who sought the origins of Finno-Ugrian and Turk languages. Collections of bronze and art objects from western Siberia and the Yenisei valley caught the attention of western and Russian archaeologists; classification of Bronze and Iron Age material started. In 1913 B. E. Petri excavated an important Neolithic stratified site at Ulan Khada, Lake Baikal region. In the 1920s and 1930s excavation was carried on by Soviet archaeologists in Altai, in the regions of the upper Yenisei, Angara, Selenga, upper Lena and Amur rivers. Princely burials of extraordinary richness were uncovered in Altai. Systematic excavations steadily continued after World War II, embracing almost all areas of Siberia and Russian Turkistan. Culturally and racially these territories are divisible into two blocks: (1) the southwestern, covering the area from the Caspian sea to the upper Yenisei, extending over the zones of semidesert, steppe and forest steppe, and (2) the eastern and northern, covering mountainous regions from Lake Baikal to the Pacific ocean and the taiga (coniferous forest) and tundra belts of northern Siberia. The first is represented by Europoid people, the second by Mongoloid. These two blocks were in conflict until the Mongoloid overflowed the Europoid in several waves.

Europoid Block in Northern Russian Turkistan, Altai and Upper Yenisei (Minusinsk) Region.—The earliest Neolithic culture is represented by the hunting and fishing culture in the steppes and in the oases, to which pointed or round-bottomed pottery was known. The small flint industry continued from the earlier Mesolithic times. In the period from the end of the 3rd millennium B.C. to *c.* 1700 B.C., food-producing economy (cattle breeding), copper, painted ware and other elements from the south entered the area. Sheep, cattle and horses were the chief domesticated animals. Copper knives and stone sledges for mining appeared. Pottery was mostly round-bottomed, decorated with geometric stamped or scratched patterns in rows. Typical burial of the dead was in a contracted position under an earth mound. Excavations in Khwarizm (Khorezm, Khiva) revealed large communal houses of oval form. In the region of the Aral sea (Khwarizm) this culture was given the name Kelteminar, in Altai and the region of Minusinsk Afanasievo, although related cultural features are found between southern Russia and the upper Yenisei. Continuous culture development is seen in the beginning of the Bronze Age in the middle of the 2nd millennium B.C. This culture, named Andronovo, is relatively uniform in this wide area in spite of some local variations. Agriculture now played an important role. People lived in earth huts, reared cattle, sheep and horses. Bowl- and flowerpot-shaped vessels were flat-bottomed, well smoothed, decorated with geometric patterns, triangles, rhombs and meanders, pointing to relationship with the painted pottery of the southern regions. Burial in contracted position persisted. The typical elements of a religion of food producers, the fire and sun cult, as well as bread offering, are evidenced. Wooden constructions in rich graves may have designated social differentiation.

Toward the end of the 2nd millennium B.C. in the region of Minusinsk a Sinid group broke in which brought with it a bronze inventory of Ordos (north China) type. Cemeteries of single graves covering the dead in extended position in stone cists, equipped with round-bottomed pots, appeared. New people mixed with the local Andronovo population. Through this immigration the so-called Karasuk culture originated and spread its influences farther to western Siberia and Russian Turkistan. Trade relations extended to central Russia. Exchange with the centres of the far eastern metallurgy introduced a new character of material culture (daggers and knives terminating in animal sculptures, series of ornaments) and stimulated the flourishing of metal industry in a wide area. The regions west of Minusinsk—Altai, Kazakhstan and Kirghizia—show variations of Karasuk culture with strong local elements with which the persistence of the ancient racial type corresponds. Chronology of this period is based on comparisons with north Chinese bronzes.

The Karasuk period persisted down to *c.* 700 B.C. From *c.* 700 to *c.* 200 B.C. culture developed along similar lines. Vital trade contact is traced from north China and the Baikal region to the Black sea and the Urals, influencing the uniformity of the culture.

TABLE I.—*Chronological Table of Southern Siberian Cultures*

Approximate dates	Aral sea (Khwarizm)	Western Kazakhstan	Altai	Upper Yenisei (region of Minusinsk)	Lake Baikal region
c. A.D. 400					
	Kushan	Sarmatian III		Tashtyk	Noin Ula
c. 100 B.C.			Shibe		Figure
	Kangli	Sarmatian II	Pazyryk	Tagar III	Graves
		Sarmatian I		Tagar II	Stone Tombs II
c. 700 B.C.	Massagetian	Sauromatian	Maiemiric	Tagar I	Stone Tombs I
c. 1200 B.C.	Amirabad Suiargan (southern elements appear)	Late Andronovo	Karasuk influenced	Karasuk	Shivera (Karasuk-like)
c. 1500 B.C.	A	N D	R O N	O V O	Glazkovo
	(local variation)				
	A	F A N	A S I E	V O	Kitoi
c. 2000 B.C.	(Late Kelteminar)				
	P	R E - A F	A N A S I	E V O	Serovo
	(Early Kelt	eminar)			
c. 3000 B.C.					Isakovo

A mounted warrior element occurred, although the agricultural and cattle breeding elements persisted. In the high Altai, Tien-shan and Pamirs appeared graves of nomadic warriors with coburial of horses. Regarding the local facies or separate political confederations, cultures of this period are called Tagar in the region of Minusinsk, Maiemiric in Altai, Sauromatian in western Kazakhstan, Sakian in Tien-shan and Pamirs, Massagetian in Khwarizm.

The art of the steppe zone from southern and eastern Russia to China developed into specific animal style. The decorative talent is illustrated in the great ingenuity which the artist displayed in filling up with animal figures a shape determined by practical ends. The elk, ram, bird, cat-animal portrayals of the middle of the 1st millennium B.C. exhibit a conjunction of the highest verisimilitude with rigorous stylization; later the organic form of the animal was ruled by extreme stylization. The elements of naturalism link this style with the naturalistic animal style of the north Eurasian forest belt. New motifs in the steppe and forest steppe belt—portrayal of groups of animals, antithetic and interwined groups of bodies, curled up animals, beasts and birds of prey—originated in a borrowing of ideas from the near east and China.

Pre-Christian culture, although influenced by the Persian empire, progressed gradually until the new flow from the east started. The territory between the lower Volga and Altai represents a unit with a common destiny. Chinese and western sources report that the Sarmatian-Sakian time was followed by the supremacy of the Huns, who dominated the western steppes as far as the Urals and the Volga. Archaeological investigations show that the east-west movement started at a time when the Hun confederation had not yet been consolidated. In east Kazakhstan appeared an eastern group of Stone Tombs people not later than the 5th century B.C. The main east-west stream ran presumably from Manchuria-upper Lena, along the northern border of the Gobi, into the Lake Balkash territory and from there on, avoiding powerful cities in Khwarizm, into the steppes north of the Caspian. For centuries up to the consolidation of the Turkish khanate in the 6th century A.D., Mongoloid components were mingling with the local Europoid, which have never been wiped out. The known pre-Turkic tribes—Massagetians, Sakians, Usuns, Khakas—all show more or less Europoid traits.

The cultural pattern from Altai to Transbaikalia in the last centuries B.C. and first centuries A.D. is largely traced to China of the Han period. Social differentiation is evidenced by princely burials, extraordinarily well preserved in five large burial mounds of Pazyryk and Shibe in the high Altai. Complete burial places were frozen and even perishable substances were preserved, including human bodies and horses with harness and saddles, textiles, felt and leather objects, clothing, fur coats, false beards, besides jewelry, mirrors, hair plaits, etc. All materials were finished with virtuosity. The art combined animal, plant, geometric and realistic human designs. Polychromy played an important part. Mummification, tattooing, scalping and the use of amulets is evidenced.

Meanwhile, in the region of the Aral sea the apogee of the

Khwarizm civilization was reached in the epoch of the empire of the Kushans. During the 1st and 2nd centuries A.D. the irrigation system attained its greatest development. Numerous cities were built along the banks of the canals.

Mongoloid Block of Northern and Eastern Siberia.—The arctic and subarctic zones exhibit a continuous culture belt in a sub-Neolithic stage from boreal times through several millenniums. Making of pottery and polishing of stones, but neither farming nor domestication of animals, except the dog, were known. People lived in small, seminomadic communities, in round, semi-subterranean houses. The arctic sea shores demonstrate sea-hunter cultures. In the north this stage of life lasted down to the present time. The region of the Amur river in east Siberia shows a long-lasting Neolithic, of which the oldest forms resemble certain finds of northern Japan (proto-Ainu) and China. Cultural continuity is traced from the Neolithic through the stages in which copper smelting and iron were known. In the farthest northeast, archaeological and other data suggest that the Kamchadal, Koryak and Chukchi entered the area from the west less than 2,000 years ago and found the coastal region occupied by a population related to the Eskimo. The Ural region was linked with the east and north Russian and west Siberian culture. During the middle and end of the 2nd millennium B.C. the culture of the middle Ural region is famous for its elk and water-bird sculptures portrayed in wood. Cultural relationship between the northern Baltic and northwestern Siberia, forming a continuum up to the early historic period, furnish this area with the characteristics of the home lands of the Finno-Ugrians.

The best-explored regions are the shores of Lake Baikal, the Angara valley, the upper Lena and the lower Selenga. The earliest Neolithic culture shows Siberian Upper Paleolithic traits; the flint tradition of small implements persisted alongside a woodworking and quartzite industry which developed as a result of adaptation to a taiga environment. Chronological phases are based chiefly on the Angara grave materials by means of stratigraphy and comparisons. The following successive cultures are discerned (terminology as used by the Soviet archaeologist A. P. Okladnikov): (1) Isakovo, showing the earliest appearance of pottery, alongside flint and bone tools (arrowheads, knives, points, half-ground adzes); the period may reach back to *c.* 3000 B.C. (2) Serovo, characterized by thinner pottery, decorated by dentate stamping, boss, pit and net impressions and by stone inventory of more regular forms; reinforced bows with bone backing and fish effigies of stone appear; the period belongs to the 3rd millennium B.C., probably to its second half. (3) Kitoi, placed before the middle of the 2nd millennium B.C., shows a variety of more developed forms of equipment; the great number of fishhooks found in the graves indicates that subsistence was now based primarily on fishing instead of hunting; sculptures of human faces in stone and stone rings appear; close parallels in stone and bone industry as well as in art style are found from northern Scandinavia and northern Russia to China. (4) Glazkovo, extending through the middle of the 2nd millennium B.C. to *c.* 1300 B.C., continues a similar mode of life; novelties include the appearance of burial mounds and burials in stone cists, copper knives and arm rings, nephrite rings and disks.

The first bronze inventory in the region of Lake Baikal is related to the bronzes of the Shang period in northern China and the earliest Ordos bronzes. Life was then of semisettled character, and cattle breeding was known. Continuity of culture in the Bronze Age stage is traced up to *c.* 300 B.C. The period between *c.* 700 and 300 B.C. in Transbaikalia, called Stone Tombs I, exhibits a transition to nomadism and mounted-warrior conditions. Cultural elements held in common with the Scythian steppe zone appear as far in the northeast as the Lena river. South-north and north-south movements are attested in the last centuries B.C. The south-north movement is assumed as Yakut migration from the Baikal to the upper Lena region, the north-south movement from Cisbaikalia to Transbaikalia as migration of the taiga group, related to the Tungus of the present day.

XV. OCEANIA

The archaeology of Oceania involves for the most part short time perspectives, because migrations within the open Pacific could have occurred only after the development of seagoing canoe navigation in Neolithic times. The exception is the New Guinea-Australia region, where the ancestors of the Australoid- and Negritoid-type peoples evidently arrived in Paleolithic times.

Records of early travelers described some of the more spectacular sites; *e.g.*, the giant statues of Easter Island and the royal tombs of Tonga. By the late 19th century a few scientific institutions and private scholars were carrying on sporadic archaeological work. Occasional finds were made in caves, as in Hawaii, or by rough excavation as when F. W. Christian in 1896 tells of tearing out the floors of tombs in the so-called Venice of Ponape (*see* below). Otherwise finds were almost all surface materials; *e.g.*, tools, stone constructions and petroglyphs. A number of local scientific institutions formed mainly in the early 20th century included archaeology among their activities, notably the B. P. Bishop museum in Hawaii. Yet even by the mid-20th century few professional archaeologists had undertaken prolonged work in the area. Fortunately "depth" excavation became a feature of studies, as by H. D. Skinner and R. Duff (New Zealand Maori), E. W. Gifford (Fiji, New Caledonia), K. P. Emory (Hawaii) and A. Spoehr (Marianas). Most territories adopted conservation laws. Successive Pacific Science congresses and Congresses of Prehistorians of the Far East materially advanced interchange of archaeological knowledge. In 1951 the Pacific Science board of the U.S. National Research council established a committee of specialists to foster archaeological work in the Pacific area.

The long-term history of the oceanic peoples, especially the Polynesians, has been the subject of many speculative theories. Professional scholars reject ideas involving a lost continent (*e.g.*, Lemuria, Mu) or direct relations with the near east (*e.g.*, the Lost Ten Tribes, migrations of "Children of the Sun" from Egypt), early India (*e.g.*, Indus valley-Easter Island connections) or Japan (*e.g.*, supposed language relations). They also insist that, while eastern-voyaging Polynesians could well have reached the American continent, and some may have found their way back into the islands, none of the various theories which claim that oceanic peoples had their homelands in North or South America are scientifically credible (*e.g.*, E. Rout's imaginative *Maori Symbolism*, T. Heyerdahl's thesis for the "Kon-Tiki" voyage). Similarly they reject theories explaining the pre-Columbian civilizations on the American continent in terms of influences by way of the tropical Pacific islands from Asia. The vast weight of archaeological as well as racial, linguistic and ethnological evidence continues to support the long-standing hypothesis of the settlement of Oceania by a succession of migrants from the southeast Asia region, with at most very minor contacts eastward to America.

The archaeological record begins when early *Homo sapiens* populations, comparable with the fossils of Wadjak in Java, Aitape in New Guinea and Keilor and others in Australia, were moving eastward. This apparently occurred during the fourth glacial epoch when sea levels were lower, land pathways perhaps generally more uplifted and interisland channels narrower than now. Early man could then migrate with lessened water obstructions from the Asiatic continental platform (Sunda shelf) through the intermediate Celebes-Molucca-Lesser Sunda zones on to the Australian

continental platform (Sahul or Papuan shelf). Some scholars suggest such movements even during the third glacial, but this seems very dubious. Core tools typologically Paleolithic and sometimes heavily patinated occur in both southeast Asia and Australia, and crude flake tools often of microlithic size are found in the intermediate zones (*e.g.*, Celebes, Timor) as well. Yet all these are surface finds or of dubious age when at subsurface levels. Doubtless most early groups moved in glacial times near shore lines now inundated, though valleys suitable for inland hunting or locally uplifted coasts might yield finds if properly searched. The vital western New Guinea region, much of which is swampy and lacking stone, has had little systematic study, and the materials reported are not typologically old.

The hypothetical picture has the isolated Australian and Tasmanian populations developing along regional and local lines characteristic of their later archaeological perspectives: generally Paleolithic, but with some Neolithic and also recent Malay trading contacts along the north coasts. The New Guinea region, however, was penetrated by canoe-migrating peoples carrying Neolithic elements which come to dominate the picture. The meagre evidence suggests that the first comers were "dry" gardeners living in semisedentary hamlets, with crude stone tools including adzes and axes of oval cross section; such shifting cultivators are found still from southeast Asia to the Solomons and New Hebrides. The Melanesian areas were also penetrated, apparently later and especially along the coasts, by village-living peoples with more sedentary cultivation, stone construction in various forms, finer tools including quadrilateral cross-section types, stone pestles and mortars, pottery and other later Neolithic elements. In New Guinea, for example, as shown by A. Riesenfeld, these influences appeared to arrive by way of the northeast coast from the outer fringe of islands, perhaps the Bismarcks, Admiralties and others. Unhappily archaeological work in all these Melanesian zones has been limited to sporadic surface collecting and recording, and to occasional tools turned up by garden workers or miners; time sequence definitions are out of the question except as they may be inferred from Neolithic chronology in southeast Asia. Information was extended somewhat through systematic excavation work in 1951 by Gifford in New Caledonia at the east end of the main Melanesian chain. This enriched knowledge of local stonework and other elements, but yielded only shorter-term chronological perspectives; his earliest radiocarbon date showing human occupation was approximately 846 B.C.

By contrast, archaeological work in Polynesia and some zones of Micronesia is considerably more advanced. For northwest Micronesia a vital clue is a radiocarbon dating of approximately 1527 B.C. from a stratified deposit excavated by A. Spoehr in the Marianas. Spoehr estimated from collateral evidence that occupation may go back to 2000 B.C. The Mariana *latte* sites (rows of capped stone pillars, probably posts of important houses), together with stone mortars, pottery and other artifacts, suggest migrations from the Philippines area in late Neolithic times. In 1954 D. Osborne began studies in the Palau area of southwest Micronesia, which may be even more important for oceanic prehistory because of proximity to Melanesia as well as Malaysia; his first reports revealed large earth platforms, widespread stonework, graves, pottery and other indications of rich archaeological deposits.

Farther east, the low coral islands of the Carolines, Marshalls and Gilberts yield limited artifacts of shell, bone and coral rock capable of some comparative study. The few high islands in this part of Micronesia, however, have extensive stone construction and other more diversified elements. Yap, for example, has stone ceremonial platforms, stepped tombs, "stone money," pottery, etc. Ponape's most spectacular site, the "Venice" called Metalanim, has several acres of stone-faced islands and canals, the principal structure being a rectangular enclosure with double walls up to 40 ft. high containing a central stepped tomb and also vault tombs. A much smaller Venice exists on Kusaie, most easterly of the Carolines. Scholars generally attribute such elaborations of the basic stonework elements, in Polynesia as well as Micronesia, to local creativity rather than undemonstrated outside influences.

Spoehr suggested that for archaeological purposes Micronesia and Polynesia may usefully be treated as a continuous zone. With them, too, may justifiably be placed the Fiji zone of eastern Melanesia, most easterly limit of the potter's craft. K. P. Emory, compiling known data on stonework in this whole area, distinguished two great types: one to the west (Micronesia, Fiji, Tonga, Samoa areas), characterized by ceremonial courts, perhaps with god houses, and platform tombs often of stepped types; the other to the east (Societies, Hawaii, New Zealand and islands eastward to Easter Island), characterized by temple structures, usually with altars, standing stones probably as back rests for gods and priests in the rituals, and cist burials within the structures. He notes the Tokelaus as having combinations of these elements, suggesting a transitional zone. From simpler shrines having a few standing stones (*e.g.*, inland Tahiti, New Zealand, small, outlying Hawaiian islands) the Polynesian temple became elaborated into various local forms including usually larger size and "megalithic" stonework. In Hawaii wooden posts or images generally replaced standing stones. In the Tuamotus huge coralline slabs were often used, and in the Marquesas the stones were sometimes carved in human (or god) form. Emory, A. Métraux and other specialists consider that such comparative study solves the "mystery" of the Easter Island statues. Rather than being relics of some lost continent or pre-Polynesian migration, they follow this last pattern of carved figures, standing on altar platforms (called by the standard Polynesian name *ahu*) in which there are cist burials. Apparently a local inventive urge toward large size, combined with the presence of easily worked volcanic tuff, produced this one of the many variants of the Polynesian place of worship.

Such local constructions, however, together with other more spectacular elements such as widely scattered petroglyphs and a dubiously old "script" on Easter Island, have less significance for historical reconstruction than detailed study of variability in minor artifacts. Skinner, Emory and R. Duff were particularly successful in demonstrating the importance of adz types for distributional studies. For example, a stepped adz type called by Emory the Polynesian adz could relate back to what H. O. Beyer called independently the Philippine adz. This is one of a number of archaeological and other parallels which suggest the Philippines area as the starting point for at least some of the migrations into the open Pacific. Chronology is still vague for the eastern zones, though Gifford had a radiocarbon date of approximately 46 B.C. from Fiji and Emory one of approximately A.D. 1005 from Hawaii. Theories of contacts with the American continent must be treated with caution so far as they lean on gross parallels such as stone images or art resemblances; the most concrete evidence by the 1950s was the presence of the sweet potato, apparently an American plant, in Oceania in prehistoric times.

XVI. THE NEW WORLD: EARLY MAN

The first scientifically controlled discovery of the remains of man in the new world, projectile points, associated with the bones of extinct animals, was made in 1926 by the Colorado Museum of Natural History under the direction of J. D. Figgins near the small town of Folsom, N.M., where the party was excavating a deposit of bones of the extinct Pleistocene animal *Bison taylori*. Over the next two years additional projectile points were found at the same site. Scientists were invited to examine them before they were removed by the workmen. In this way scientists not

associated with the excavations corroborated the authenticity of the discovery. Although numerous reports of projectile points associated with extinct animals had been made for nearly a century, practically none had been excavated under scientific controls and extreme scepticism marked the attitude of scientists toward any claim that the remains of man in the new world could be contemporaneous with the long-extinct animals of the Ice Ages. Therefore, the discovery near Folsom is of the greatest historical importance in proving that man lived at the same time as the extinct animals and derived his food, in part at least, by hunting them. Since 1926 numerous discoveries of tools and weapons have been found under rigidly controlled scientific conditions in North, Central and South America, so that a whole new area of study developed in American archaeology, that of Early Man.

The beginning of the period of Early Man must date from his earliest appearance on the continent, the exact time of which cannot be fixed. The close of the period probably varies in different parts of the continent. Generally, the practice is to fix an arbitrary point in the development of new world prehistory. In this article Early Man will be understood to be that population which was contemporary with the Pleistocene fauna, as shown by association in excavated sites or sites of the same age as determined by methods of dating other than the association with extinct animals.

There is no reason to believe that the extinction of the Pleistocene animals occurred throughout the continent at the same time. Following the last Ice Age there were three great climatic changes: increasing temperature and decreasing rainfall, high temperature and aridity, and cooler and moister to the climate of the present, in that order. These climatic conditions did not press equally on all parts of the hemisphere nor even on the North American continent. The climatic changes affected the vegetation, which in turn caused critical problems of adjustment for those animals which were adapted to the previously established environment. The climatic changes and the disturbance of the food supply in some areas and its destruction in others contributed directly and indirectly to the extinction of the Ice Age animals, as did the hunting activities of man. Some geographical areas probably offered more favourable conditions for survival than others. It is because of these variables that it is unwise to try to be precise in fixing a date which terminates the period of Early Man.

In the eastern United States, with few exceptions, the earliest evidence of human occupation dates from a period called the Archaic, following the extinction of the Pleistocene animals. The Archaic period will not be discussed here (*see* sec. XX, below), but attention will be called to the few evidences of Early Man in that area.

Early Man must be discussed in terms of his tools, weapons, hunting practices and a few other odds and ends of his life as indicated by objects from archaeological sites. It is uncertain what Early Man looked like, for there is insufficient skeletal material to use as a basis for an opinion.

The customary method of naming the tools of Early Man has been to assign them group names, such as the Folsom complex, after the name of the site or nearby locality where the discovery was first made. Particular types within complexes have also been so designated. Thus the Llano complex, a name suggested for a hunting culture found throughout a section of the American southwest and the southern plains, was first recognized in a region known as the Llano Estacado or Staked Plains. The characteristic points of the suggested Llano complex are known as Clovis Fluted, named for Clovis, N.M., near which they were found. Where there is a succession of developments in what is thought to be the same culture, the word stage has also been used to indicate the different periods through which the culture has passed, such as Sulphur Springs stage, Chiricahua stage, within the Cochise pattern.

Authenticated discoveries of Early Man have been made in Oregon, northeastern California, Nevada, Arizona, New Mexico, Colorado, Nebraska and Texas. Less well-authenticated instances are found in Kansas, Wyoming and North Dakota. (In the last two cases the age indicates probable Early Man sites but the animals are not identified as Pleistocene). Stray Folsom points have been found in other states, Saskatchewan and Alaska. On the basis of the equivalent fluorine content of human bones and animal bones from the same level, association should be accepted for previously questioned finds from California, Mississippi and Florida. In Mexico finds come from near Tepexpan, approximately 50 mi. N.E. of Mexico City in the Valley of Mexico. In South America two caves from near the extreme southern tip of Patagonia, a site at Punín in the highlands of Ecuador, and caves in the Lagoa Santa region of the highlands of east Brazil have shown Early Man's occupation of that continent. These sites from Alaska to Patagonia show that Early Man occupied practically the whole hemisphere.

In North America there are two great geographical regions from which most of authenticated finds come, the high plains east of the Rocky mountains and the basin-range area between the Rocky and the Cascade-Sierra mountains from the Columbia river on the north to Mexico on the south. These two areas represented different ecological regions; accordingly, in the high plains Early Man's economic activities were largely confined to hunting, while in the western area he was a gatherer of seeds as well as a hunter. A third area, crescent-shaped, with one horn in southeastern Arizona and the other probably in Nebraska, joins these two areas in a way not clearly understood and represented by the Llano complex. Information indicates both a hunting and gathering area and hunting only in the eastern part.

In view of the vast area involved and the relatively small number of sites excavated, final statements cannot be made about the relations of these three areas to one another, nor to Mexico nor South America. The brief discussion that follows is not based on relative antecedence of one area to another but on the regional manifestations.

Folsom Complex.—The Folsom complex of the high plains has as its most distinctive feature a skilfully made projectile point. This point varies in size, but most specimens do not run more than two inches in length. The greatest width is usually somewhat toward the point from the centre so that the sides converge slightly to a concave base. After the point had been completely shaped, a long flake was detached from each surface to produce a channel reaching nearly to the tip. Into these channels was fastened the end of the arrow shaft. Finally, the edges at the base were ground off to prevent their cutting the sinew thread used to fasten the point to the shaft. Knives made on the same general pattern but longer and heavier than the points are also found, more often with one but sometimes with two channel flakes removed. These two artifacts are the only distinctive traits of the tool assemblage of the Folsom hunters.

The Folsom remains are associated primarily with skeletal parts of the Pleistocene bison *Bison taylori*, although the remains of other animals are sometimes present. There is a complete absence of grinding tools in the Folsom sites, and the usual inference has been that the whole economy was based on hunting. Such high degree of food specialization is doubtful in view of the evidence that Paleolithic man in the old world was a gatherer as well as a hunter, at least in season. It may be that most Folsom sites represent hunting camps or actual kill sites rather than housekeeping sites. However that may be, evidence shows Folsom man to have been a hunter on the high plains whose life was closely adapted to the bison and its range.

In the early stages of research on Folsom man it was assumed that the artifacts associated with him represented the culture of the earliest migrants into the new world from Siberia by the way of Alaska. This theory found support in the distribution of Folsom points along the Yukon and the area north of the Brooks range in Alaska. Later it was called into question and another advanced which would have the origin of the Folsom complex in the southern high plains where specialization of hunting activities occurred and the bison came to displace the horse, the camel and the mammoth. Then as the bison gradually moved northward, following the shift of range with the changing climate, the hunters followed them. At present decisive evidence is lack-

ing in favour of either of the competing and contradictory theories.

Llano Complex.—The Llano complex is characterized by a projectile point which has much the same shape as the Folsom but tends to be a little larger; instead of two channel flakes there is generally a short one on each side. Some of the points show that a number of narrow parallel flakes were detached by pressure to produce the channel or fluting. These points are called the Clovis Fluted. The rest of the assemblage of artifacts, such as scrapers, are no more diagnostic of age or cultural position than those of the Folsom complex.

The economy of the Llano people is not clear, largely because there is no agreement on the place of the Sulphur Springs stage of the Cochise basic pattern in the over-all picture. The Sulphur Springs stage shows a heavy dependence on seed gathering as inferred from the great number of grinding stones. The Llano sites, on the other hand, are those of hunters of the mammoth, the horse (*Equus*) and the camel. Emil W. Haury believed the Llano hunters were somewhat earlier than the seed gatherers, but until dates are available which separate them sufficiently in time to prove this, it is also reasonable to think of them as representing different facets of the economy of the same people as related to the seasonal opportunities of the environment. The bison does not appear to have been a food animal of significance in this area. In addition to the animals already mentioned, the following are probably to be associated with the Llano complex: jaguar, tapir, sloth and dire wolf, all extinct varieties.

A bone projectile point (234 mm. long and 17 mm. in maximum diameter) comes from the same horizon as the Clovis Fluted points at the original site. It is pointed at one end and beveled for lashing to a shaft at the other. This point, used by the elephant hunter, has been found in Oregon, northeastern California and Florida.

Excavations at the Clovis locality by the Texas Memorial museum in 1949–50 showed that, there at least, the Clovis Fluted points are earlier than the Folsom and that the associated animal assemblages are those which have been described above for the two complexes. It is this stratigraphic relationship and the different animal assemblages which in part gave rise to the theory that the Folsom complex is derived from the Llano.

In the great basin both cave and open sites have shown Early Man to have been both a hunter and gatherer. Thus his economy was clearly more like that with which we are familiar for primitive peoples. There is no distinctive type of projectile point that characterizes this area. Points tend to be notched either at the corners or on the sides, although some strongly suggest the Clovis Fluted, and others have a slightly constricted base giving a triangular-shaped end. Dry caves in Utah, Nevada and Oregon have preserved much more evidence of the utensils of the early inhabitants than have the open sites of the other regions. Basketry, cordage, sandals, spear throwers and many other objects give a fuller picture of the economy and technique of adaptation of these hunters to their environment. In this area the extinct animals closely approximate those of the Llano complex. They include the sloth, a variety of elephant (probably mammoth), camel, horse and bison, though the species of the latter is indeterminable. The greater variety of seeds and nuts in this region than in the grasslands of the high plains provided an opportunity which the inhabitants seized upon to enrich their food supply. The use of grasses, tule (*Scirpus lacustris*), sagebrush bark (*Artemisia tridentata*) and bast fibres of various sorts for basketry, cordage, mats, sandals and probably other articles of clothing, and the employment of greasewood (*Sarcobatus vermiculatus*) for projectile foreshafts indicate a wide range in the exploitation of the environment.

The discovery of Tepexpan man in the Valley of Mexico in 1947 and the excavation in 1952 of the skeleton of a mammoth associated with projectile points and scrapers were noteworthy extensions to this area occupied by Early Man. The points are not similar to the Clovis Fluted but the period is probably the same as that represented by this type of point.

J. B. Bird's excavation of Palli Aike and Fell's caves in southern Patagonia revealed human remains associated with those of the sloth and horse (*Equus*) in the earliest stratum. Projectile points from this level are mostly stemmed. Scrapers, bone flaking tools and lava cylinders are reported. Cremation was practised. One reconstructed skull suggests the Lagoa Santa type from eastern Brazil, an area of Early Man occupation as shown by the excavations of Confins cave.

The hunting methods of Early Man were to a large extent governed by the kinds of available weapons. Probably a thrusting spear, the spear thrower, clubs and rocks were used to dispatch large animals. A long, knifelike stone blade may have been used as a spear point or a knife or both, depending on the owner's needs of the moment. Many sites of Early Man are in old bogs and adjacent to water holes. Animals were probably driven into the marshy ground and killed or were killed after having been found mired there. The "animal drive" method of hunting occurs in the Paleolithic of Europe, and its use in the new world by Early Man shows that the technique had apparently a worldwide distribution at a very early period.

Chronology.—The development of the radiocarbon (C^{14}) method of dating has given a series of dates for Early Man sites in the new world that has systematized to a greater extent than formerly knowledge of the early occupation of the hemisphere. At the same time it has helped formulate some of the most pressing problems in this field. Radiocarbon dates are derived from two kinds of sources: actual artifacts, and charcoal or burnt bones, which are used as indirect evidence of human occupation. The number of dates derived from artifacts is limited, partly because those made of cellulose material from this period are scarce and the finder hesitates to sacrifice them, especially if there is only one. Some artifacts have had to be treated with preservative to remove them for study and are thus rendered useless as a source for radiocarbon dating. The oldest artifact from the new world is a pair of sandals from Fort Rock cave in Oregon with a date of 9053 ± 350 (7103 B.C.). (All C^{14} dates are reckoned in years before the present, B.P.) Atlatl foreshafts (the atlatl was an instrument for throwing a spear) from Nevada are 7038 ± 350 (5088 B.C.) years old. Dates derived from sloth dung covering occupational material, from charcoal of fireplaces and from burnt bones show that Early Man was in the great basin more than 10,000 years ago, as was the case for the high plains. The age of the burnt horse and sloth bones from Palli Aike cave is $8{,}639 \pm 450$ (6689 B.C.) years, thus indicating that man had made the long trek from Alaska to the tip of South America close to 10,000 years ago. C^{14} dating showed for North America that the occupation of the two great regions, the high plains and the basin-range province, was contemporaneous. In view of this similarity in time, the differences in culture and exploitation of the environment in the two areas is a problem of considerable interest.

Some problems confronting the student of Early Man are: (1) When did Early Man first enter the new world and at what place or places? (2) What areas did he pass through in his occupation of the hemisphere? (3) Was more than one major north-to-south route followed at different times, as is suggested by the contemporaneity of the cultures of the high plains and the great basin and their mutual exclusiveness as far as distinctive weapons are concerned? (4) What is the relation of the Clovis Fluted point (Llano complex) to the Folsom point (Folsom complex)? (5) Was there a northward movement of the Folsom hunters as has been suggested? (6) What was or were the line or lines of migration followed into South America?

XVII. SOUTH AMERICA

The archaeology of South America covers a span of human his-

tory going back approximately 10,000 years. The earliest inhabitants of the continent were migrant hunters who followed a way of life similar to that of the first occupants of North America. They were related to these early North Americans in that both belonged to an American Indian racial stock which had its origins among the Mongoloid peoples of northern Asia. About 15,000 to 20,000 years ago, if not earlier, these northern Asians entered the Americas by way of the Bering strait. By 7000 B.C. some of them had reached the southernmost tip of South America, where evidences of their camps have been found in caves along the Straits of Magellan. By the 2nd millennium preceding the Christian era the American Indian occupied most of the two continents, and he had developed a native agriculture based upon maize and manioc. A sedentary village life—comparable with the farming communities of the old world Neolithic stage—was founded upon this agricultural economy. The origins of this American "Neolithic" appear to lie somewhere in Mesoamerica (Middle America) and Andean South America. Perhaps both areas progressed more or less simultaneously with a gradual interchange of ideas between them. Certainly, by 1000 B.C. the Indian civilizations of both Mesoamerica and Peru had achieved large permanent villages, pottery making, weaving, stone carving, distinctive art styles and specialized architecture. The prehistory of South America is to a large extent the history of the spread and development of this sedentary agricultural way of life throughout the continent. In Peru, where such a "Neolithic" or Formative base was attained early, the story is one of successive elaborations —both technological and social—deriving from it. In the northern and southern Andes and throughout much of the tropical lowlands this "Neolithic" basis of civilization was established in prehistoric times, but subsequent achievements never measured up to those of Peru. Elsewhere, in areas such as the Gran Chaco, Patagonia or the hinterlands of eastern Brazil, the agricultural technology of the Formative was never adopted, and in these regions the Indians continued an existence similar to that of the first hunters, fishers and gatherers who occupied South America.

The principal objectives of South American archaeology in the 20th century have been those of culture distribution and sequence. In some areas, as in Peru, it has been possible to work back from the ethnohistoric documentary materials on the 16th-century Inca empire into the fully prehistoric periods. In other localities documentary sources are less adequate, and it has been impossible to set up ethnohistoric-archaeologic base lines. However, in some regions, such as remote sections of the tropical forests or Tierra del Fuego, Indian groups are still living in accordance with old aboriginal customs, and these tribesmen and their ways and handicrafts can be related directly to archaeological evidences found in the immediate territory.

Systematic archaeological research has advanced more rapidly in Peru than in any other area of South America. The German scholar Max Uhle was the first scientific pioneer in this field. By the first decade of the 20th century he had set up the major outlines of Peruvian archaeological chronology. A. L. Kroeber expanded and refined the Uhle scheme, and further research by Peruvian, North American and European students developed an impressive corpus of knowledge for the area. In this connection, radiocarbon dating became important in establishing absolute dates. In general, the prehistory of the north and south Andes is less well known than that of Peru, and lowland South America is even less systematized than the north and south Andes. An outstanding exception to this is the West Indies, where Irving Rouse worked out detailed sequences and distributions of cultures for the islands.

A. Natural and Cultural Areas

The natural environment of South America varies dramatically, and changes in land form, vegetation and climate are accompanied by marked differences in human cultural adjustments. The ten areas which are used here, and which have both natural environmental and cultural distinctiveness, are defined and characterized as follows:

1. Southern South America: Uruguay, the Argentine pampas and Patagonia, Tierra del Fuego and the Chilean archipelago. For the most part, this is low-lying country with sparse forest cover. Climate varies from subtropical to cold temperate. In pre-Columbian times agriculture was not successful in the heavy soils of these regions.

2. The Gran Chaco: the adjacent portions of Argentina, Paraguay, Bolivia and Brazil. Terrain is flat and low, climate varies from semiarid to tropical, and wet-dry seasons are marked. Vegetation is predominantly scrub. This was not an area favourable to primitive agriculture.

3. Eastern Brazil: the narrow coastal plain and interior uplands of Brazil south of the Amazon. This is semiopen, parklike and grass-covered country except for the dense forests along the major rivers. Climate varies from tropical to subtropical. Some native agriculture was practised along the rivers, but the area was largely nonagricultural.

4. The Amazonian lowlands: the vast lowland territories of the Amazon system except for the east Brazilian uplands. This is tropical country with alternating river forests and open grasslands. Native agriculture—especially manioc—was important.

5. Venezuela: the area of the modern republic and the adjoining Guianas. The coast varies from semiarid to swampy. There are tropical river valleys and open grasslands or llanos in the south and west. Native agriculture was of importance in some regions.

6. The West Indies: all the islands from Trinidad to Jamaica and north to and including the Bahamas. Agriculture was of importance on these tropical islands except for the western part of Cuba.

7. The Central Andes: the Peruvian coast and highlands and the adjoining highlands of Bolivia. An area of tropical latitudes in which climate varies greatly depending upon elevation. Agriculture was of great importance, with native irrigation and terracing highly developed in the oasis valleys of the desert coast and in intermontane highland basins.

8. The South Andes: the Chilean coast and highlands and the adjacent highlands of Argentina. This is an area of extreme to moderate aridity with a temperate climate. Agriculture was practised in pre-Columbian times but was of less importance than in the central Andes.

9. The North Andes: coastal and highland Ecuador and Colombia. Tropical to temperate country, depending upon the elevation, in which native agriculture was of importance.

10. Lower Central America: Panamá, Costa Rica, Nicaragua and eastern Honduras. Tropical country of varied terrain. The northern frontier is a cultural one, being the limits of Mayan and Mexican cultures of Mesoamerica. Native agriculture in this area was similar to that of the north Andes.

Southern South America.—Archaeological sequences along the Straits of Magellan reveal an ancient land-hunting economy going back as much as 9,000 years. The earlier periods of this sequence may relate to cave finds as far north as Buenos Aires province, and the middle periods clearly affiliate with the pampas and Patagonia as demonstrated by the common possession of certain projectile point forms and the bola stone. To the north, along the Paraná river, prehistoric sites show the refuse remains of hunting and fishing peoples who manufactured unpainted pottery decorated with incisions and punctations. Pottery of this tradition diffused southward to the pampean and Patagonian guanaco hunters. In very late prehistoric times Guaraní Indians who practised agriculture and made painted pottery, settled in small, isolated communities around the delta of the Río de la Plata; but the Tehuelche, Puelche, Querandí, Charrua, Chaná and other early historic tribes, whose cultures are derived from the old local hunting tradition, continued in control of most of the area.

The Gran Chaco.—Little archaeological information is available from the Chaco. Inhabited in historic and modern times by tribes who were essentially hunters and gatherers, there is reason to believe that the prehistoric populations of the area followed a similar pattern of life. Only small refuse sites and cemeteries have been reported. The prehistoric and protohistoric

pottery is plain or very simply decorated with finger and stick impressions. Some of the modern tribes manufacture a pottery decorated with cord impressions and unfired pigments, and occasional potsherds of this kind have been found in prehistoric sites. Ceramic evidences suggest that there have been contacts between the peoples of the Chaco and the Guaraní and Paraná river pottery-making traditions to the east. Some authorities have noted rather vague resemblances to the prehistoric ceramics of the Argentine Andes, Bolivia and Peru.

Eastern Brazil.—In the state of Minas Gerais remains of an early longheaded Indian population, the Lagoa Santa, have been found associated with a prepottery culture. This prepottery culture of the Minas Gerais caves is characterized by a crude chipped ax which is also a common artifact type in the earliest-known period of the Brazilian coast, the Archaic phase of the sambaquis or shell mounds. In Minas Gerais the prepottery culture is succeeded by one which possesses plain pottery and polished stone celts. On the coast the Archaic phase is followed by the Southern phase of the sambaquis. The Southern phase is noted for its fine work in ground and polished stone, including axes and celts, plummetlike stones and a variety of effigy dishes. Pottery occurs in the coastal shell mounds only in the latest levels and is attributed to the Tupí-Guaraní peoples. A reasonable hypothesis is that the Archaic and Southern phases of the sambaquis are the remains of hunting and gathering peoples such as the Botocudo or the Patashó and that these tribes were pushed back from the coast by the incursions of Tupian-speaking groups.

The Amazonian Lowlands.—Large native towns, long since vanished, once existed along the Amazon and its major tributaries. These ancient populations left little in the way of permanent architecture and are known largely from their ceramics and burials. On the island of Marajó, in the Amazon delta, a culture sequence reveals a long period of occupation by hunting and fishing tribes prior to the advent of the people responsible for the handsome red, black and white and modeled burial urns. The makers of this fine pottery, known as the Marajó style, were sedentary village agriculturists who appeared suddenly at the delta and disappeared just as rapidly. They were succeeded, once more, by simple fishers and hunters. The origins of Marajó civilization are obscure, but it is probable that its centres were westward somewhere in the middle or upper drainages of the Amazon.

Near the confluence of the Amazon and the Tapajoz is another important prehistoric phase, the Santarém. Santarém pottery is ornately modeled rather than painted. The style has no known close relatives in the Amazon drainage, but there are some similarities to pottery found along the middle Orinoco in Venezuela. Like Marajó, Santarém is a fully prehistoric complex with no contacts with the historic horizon.

A number of scattered pottery finds, mostly burial urns, have been made along the middle Amazon and on several of the upper tributaries. Some of these show suggestive parallels of form and decoration to the Marajó style. Apparently the vast water network of the Amazonian system made possible widespread cultural contacts, but, except for the region of Marajó Island and the delta, little is known of culture sequence and development.

Venezuela.—Venezuela is a meeting ground of two major streams of cultural influence, those of the tropical lowlands, which centre on the middle and lower Orinoco river and which may have some affinities with the Amazon, and those of the sub-Andean highlands to the west, which link closely with northeastern Colombia.

On the lower Orinoco a white-on-red pottery style is the earliest-known period. This style, the Saladero, is followed by the modeled and incised Barrancos style. This succession of ceramic types on the Orinoco has a direct bearing upon culture sequences in the West Indies, which seem to be closely related to those of Venezuela.

Andean Venezuelan cultures have traits which point westward. These include such ceramic features as ring-stand and tripod bases for vessels, black-on-white painting and figurines.

A preceramic phase, the Manicuare, also was discovered in Venezuela. It is not clear if the Manicuare culture relates to the preceramic period of the West Indies.

The West Indies.—The preceramic cultures of the West Indies are sometimes referred to as the "Ciboney," a name applied to a primitive, nonpottery group living in western Cuba at the time of the Spanish conquest. Some authorities have suggested that the Ciboney entered the West Indies by way of Florida, but this point is debatable.

Pottery-making agriculturists, presumably of the Arawakan linguistic family, appear to have swept out into the Antilles from Venezuela in two major waves. The earlier invasion is marked by the white-on-red pottery of Saladero derivations and the later invasion by the incised and modeled Barrancos-derived pottery. The climax of West Indian native civilization came in the later period and had its focus on the island of Puerto Rico. An outstanding feature of West Indian Arawakan culture was a ceremonial ball game played in a specially constructed stone-walled court.

The Arawaks were suffering from the inroads of the Caribs, another mainland South American tribe, when Columbus discovered America. Within 50 years the Spanish had established their first permanent bases in the Americas, and the native cultures and peoples of the West Indies were destroyed.

The Central Andes.—Along the north coast of Peru are deep refuse deposits of early fishing and agricultural communities which date back as early as 2500 B.C. Maize was unknown at this time, but a number of roots and beans were domesticated, as was cotton. Houses were subterranean pits lined with boulders or hand-made adobes. Plain pottery first appeared at 1200 B.C.

About 800 B.C. maize and decorated pottery of the Chavín style appeared in the middens. Aboveground houses became common at this time, and there was a shift away from the immediate shore line back into the coastal valleys, which suggests the increased importance of agriculture and, perhaps, the beginnings of irrigation. This Chavín period, with maize and a full agricultural economy, marks the inception of the Peruvian Formative, or "Neolithic," cultures.

Permanent temple structures of adobe and stone were erected in the Chavín period, but the greatest politico-religious structures date from the succeeding Classic stage (*c.* A.D. 300–1000). These were the mammoth adobe pyramids of the Mochica civilization of the north coast, the stone temples of the Recuay culture of the north highlands and the huge stone enclosures of Tiahuanaco of the Bolivian altiplano. The Classic stage also saw a climax in the arts as evidenced by the Mochica portrait pottery, Nazca ceramics and textiles and Tiahuanaco stone carving. Metallurgy was also developed during the Classic. Unlike Classic Mesoamerica, however, the Peruvians did not evolve a complex calendar or system of writing.

The close of the Classic stage of Peruvian civilization is signaled by a widespread decline in religious architecture and a general falling off of the arts. Technological advances are noted, however, in metals, with increased use of copper and bronze for tools and weapons. A new type of settlement—a planned compound-type community in a walled rectangle—is seen in many parts of the area. Concomitant with this change is the Peruvian-wide diffusion of an art style referred to as "Tiahuanacoid." This Tiahuanacolike art, named for its similarities to the sculptured designs of the old Classic centre of Tiahuanaco, may have been the symbol of an empire which served as a prototype for the later Inca state. These Tiahuanacolike influences disappeared around A.D. 1200, and a number of local kingdoms—each with its own distinctive art style—sprang up. The Chimu nation, on the north coast, is one of the best known of these. Early in the 15th century the warlike Inca, beginning at Cuzco in the south highlands, embarked on a program of conquest and expansion that was to carry them north to Ecuador and deep into Chile. Overrunning the local kingdoms, they were masters of the situation by 1530. They were, in turn, overthrown by Francisco Pizarro in 1532.

The South Andes.—The South Andes were marginal to Peru-

Bolivia in their cultural development. On the north coast of Chile, at Arica and Pichalo, preceramic, nonagricultural fishers continued in this mode of existence long after agriculture and pottery had become established in Peru. Maize and ceramics appear to have been diffused to north Chile as late as the end of the Peruvian Classic stage (*c.* A.D. 1000), although this important question is not settled. The Arica culture on the Chilean coast and the Atacameñan culture of the interior desert oases of north Chile persisted until the Inca conquest of this region. Atacameñan towns were small and compact, and subsistence was based as much upon llama and alpaca herding as upon agriculture. A similar civilization, that of the Quebrada de Humuhuaca, was developed contemporaneously in the far north of Argentina. Farther south, around Serena in Chile and in the adjacent portions of the Argentine Andes, was the Diaguita civilization. Its local prototypes are not fully known, but certain features of Diaguita pottery and metalwork suggest remote and indirect Tiahuanaco influences. Inca influences in these regions are seen in architectural and artistic changes, but for the most part these are rather superficial.

The North Andes.—Peruvian influences are not so clearly registered in the archaeology of Ecuador and Colombia as they are in the south Andes. This does not mean that they are nonexistent or unimportant, but the picture of prehistoric development is more complex in the north. One of the reasons for this is that strong currents of counterinfluences were moving into this area from Mesoamerica and, probably, from Venezuela. On the coast of Ecuador there is a culture sequence which probably goes back as far as the Peruvian Chavín period and ends with the Manteño civilization of the late prehistoric and protohistoric periods. On the coasts of Guayas and Manabí the Guangala and Cerro Jaboncillo cultures appear to mark a peak in artistic development that may be comparable with the Peruvian Classic stage. It should be emphasized, however, that these Ecuadorian coastal cultures are not Peruvian in any specific sense. Adobe pyramids are found on the Ecuadorian coast, but ceramic styles are distinctly local. Of special interest is a figurine art based upon a mold technique. This figurine tradition extends north along the coast to Esmeraldas and to Tumaco in Colombia. Slight correspondences to Mesoamerican figurines have been noted.

Colombian prehistoric cultures are sharply divided into a number of small regional centres. In the absence of reliable chronologies for most of the area it is impossible to arrange these developments in sequence, although some of them, such as the Chibcha centring upon Bogotá, were clearly protohistoric. The stone monuments of San Agustín, in southern Colombia, may be distantly related to Peruvian highland cultures such as Recuay and may be equally old. In northeastern Colombia, pottery sequences indicate a long occupation and one which is allied to western Venezuela, underlying the protohistoric civilization of the Taironas.

Lower Central America.—In Panamá, an early shell-mound culture, quite possibly preagricultural, has been discovered on the Azuero peninsula. This shell-mound culture, the Monagrillo, antedates the later agricultural, pottery-making civilizations; but Monagrillo ceramics bear no resemblance to those of these later cultures such as the Coclé or the Veraguas. It is of interest that Coclé and Veraguas metal ornaments are highly similar to those of Colombia, and there are also ceramic affinities between these late prehistoric cultures of Panamá and northern Colombia. In Costa Rica and Nicaragua the Nicoya polychrome style of pottery has similarities to certain Mexican styles, but there are also pottery strains in these regions which appear to derive from Panamá and even farther south. By the 1950s, nothing had yet been found in lower Central America—with the possible exception of Monagrillo—which could be demonstrated to be as early as the pre-Maya Formative cultures of the Ulúa valley in Honduras.

Whether all of Nicaragua, Costa Rica and Panamá was unsettled during the Formative stage in Mesoamerica (*c.* 1600 B.C. to A.D. 100), or whether the earlier periods had not yet been disclosed, remained to be seen in the 1950s.

B. Internal and External Relationships

The long culture sequence on the Peruvian coast, with the appearance of domesticated plants at 2500 B.C. and of maize and Chavín pottery at 800 B.C., is not duplicated elsewhere in South America. This fact, plus the high developments of native civilization in the central Andes, argues for Peru as an important centre of "Neolithic" beginnings. The south Andes appear to have received the stimuli for a "Neolithic" or Formative type culture from Peru, and the diffusions of these stimuli may have taken place as late as A.D. 1000. The relationships between Peru and the Amazonian lowlands were still a mystery at mid-20th century. There had been insufficient archaeological investigation on the upper Amazon to determine culture sequences or approximate ages of cultures. The evidence at Marajó Island, at the mouth of the Amazon, suggested that tropical forest civilizations developed on the upper drainages of that river and moved eastward; but this was still largely a matter of speculation. There was also the possibility that the tropical forest influenced Peru in the early periods. J. C. Tello of Peru advanced the theory that Andean agriculture and the Chavín culture had their beginnings on the eastern forested slopes of the Andes. At mid-century, however, there was no substantial evidence to support this hypothesis. One of the most promising areas in which to investigate Andean-lowland relationships is the north Andes, particularly Colombia. It is noteworthy that certain human effigy burial urns of the lower Magdalena valley in Colombia have widespread Amazonian parallels. The direction of movement of such traits is, unfortunately, still unknown.

The question of relationships between Peru and the north Andes leads into the problem of the wider interrelationships of South American civilization. What are the connections between Peru and Mesoamerica? For the most part the similarities that exist between these two major centres of the new world are those of basic inventions rather than specific customs or styles. Maize and a number of other domesticated plants are held in common. Similarly, pottery making, weaving, stone carving and the building of great pyramids as bases for religious buildings are common achievements. It seems most likely that such ideas and techniques were exchanged at an early time, probably at the beginnings of the Formative cultures in each area. Radiocarbon dates would appear to favour the priority of Mesoamerica in these exchanges, but the problem is by no means resolved. Besides these various basic traits which the two areas share, there are a number of secondary traits which clearly point to diffusion between such distant points as Peru and Mexico. Metallurgy is one of these. It has a long history in Peru and Ecuador and is widespread in Colombia and parts of lower Central America. As opposed to this it makes a late appearance in southwestern Mexico, so that there seems little doubt that it was a technological complex diffused from south to north at a relatively late prehistoric date.

There is, finally, the question of transpacific contacts between Oceania and southeastern Asia and the west coast of South America. Various theories have been put forward for prehistoric migrations in both directions. That such occasional voyages may have been made is not beyond the bounds of possibility. It is, however, unlikely that they had profound effects upon the course of native South American civilizations, which are, in their racial histories, languages and cultural patterns, distinctly autocthonous.

XVIII. MESOAMERICA

Geographic Limits and Cultural Characteristics.—Central and southern Mexico, Guatemala, British Honduras, El Salvador and part of Honduras are recognized by archaeologists to have constituted a cultural unity in pre-Columbian times. The name Mesoamerica is now generally used to refer to this culture area. Its limits are defined by lines roughly drawn from the mouth of the Pánuco river to the mouth of the Grande de Santiago river on the north and from the mouth of the Ulúa river to the Gulf of Fonseca in the south. Within these geographic limits, peasant cultures of Neolithic type developed into civilizations—comparable with the early civilizations of the near east, the Indus valley, the Hwang-ho valley and Peru—during the 3,000 years prior to the Spanish conquest.

The beginnings of sedentary life based on cultivation of plants have not been found in Mesoamerica, and it is not possible to link the early hunting and gathering cultures (*see* sec. XVII, above) with the oldest-known farming cultures. With regard to the birth of the Mesoamerican civilizations, most of the elements which serve to define this stage of cultural development appear in the last centuries B.C. of the beginnings of the Christian era. These traits are: full-time specialization, extended trade, social stratification, theistic religion and priestly hierarchy, writing, mathematics, astronomy, calendar, monumental architecture and urban centres of considerable size. However, metallurgy—associated in the old world and in Peru with the first phases of civilization—did not become widespread in Mesoamerica until after A.D. 1000, and even then metal (gold, silver, copper) was mostly used for ornaments and for specialists' tools; only in western Mexico did metal digging tools become a part of the farmers' equipment.

The most significant archaeological data on the growth of Mesoamerican civilizations are presented in what follows in the form of regional sequences.

Central Mexico.—Leaving out the evidence for early hunters and food gatherers, in the continuous sequence from the earliest-known farming cultures to the Spanish conquest, five major epochs may be distinguished. These are: Archaic, Teotihuacán, Toltec, Chichimec and Aztec. The last three are defined on historical rather than archaeological grounds.

The early Archaic phase is represented by remains of a peasant culture found in the lower levels of deep middens at El Arbolillo and Zacatenco, in the foothills of the Guadalupe range, north of Mexico City. Maize was cultivated. Hunting and seemingly fishing too (for the sites were located on the shore of the then existing lake) played a secondary role in the economy. Vestiges of woven cotton surely indicate commercial relations with less elevated regions, probably Morelos and Guerrero, for the Valley of Mexico is too high for the cultivation of this plant. Shell ornaments made from Pacific coast species are another indication of external trade. Long permanent settlement is indicated by thick deposits of refuse. The houses had mud-daubed walls and probably thatched roofs. Quite elaborate ceramics point to a long tradition of pottery making whose origins are still to be found. Hand-made terra-cotta figurines, always representing women, may be interpreted as indication of the mother-earth religious concept.

To the middle Archaic phase belongs the large cemetery of Tlatilco, west of Mexico City. There, several hundred burials have been found. The contents of the graves indicate a much more developed culture. There are evidences of human sacrifice; indications of fashion such as artificial head deformation and tooth mutilation; clay masks; flat and cylindrical clay stamps; terra-cotta figurines representing warriors, shamans, dancers and acrobats; and luxuries such as jade and pyrite. Although the evidence for houses is scanty, there is no doubt that the site was a large settlement; numerous narrow-mouthed conical or bottle-shaped pits four to five feet in depth, found filled with rubbish, seemingly served originally for storage purposes. Common to Tlatilco and to a number of contemporary sites—such as Gualupita and Atlihuayan—in the Valley of Morelos, are traits of the so-called Olmec style. These traits are infantile features in the representations of the human figure, and jaguar motifs which surely indicate some religious symbolism. According to present evidence, this style seems older in central Mexico—and also in Oaxaca—than in the Olmec region of southern Veracruz and Tabasco.

The last Archaic phase witnessed the beginnings of monumental religious architecture, represented by the truncated conical platforms of Cuicuilco, south of Mexico City. The largest of these platforms is 130 yd. in diameter at the base and 74 ft. high. The earth nucleus was faced with retaining walls of undressed stones. There were altars on the summit. The lava flood produced by the eruption of the neighbouring Xitle volcano put an end to the occupation of this site. Elsewhere, there is evidence that the Archaic period lasted for a few centuries afterward.

Radiocarbon dates for the Archaic period range from 1400 B.C. for early Zacatenco to 500 B.C. for the eruption of the Xitle.

Teotihuacán, 25 mi. N.E. from Mexico City, is the type site for the second major epoch. The earliest remains of occupation found at this site are pottery (of late Archaic type) incorporated into the building material used for the oldest edifices. These were built some time after the eruption of the Xitle and probably no later than the time of Christ. From this beginning to the destruction of the city there was a single, continuous occupation. At about A.D. 300 the urbanized area covered a minimum of 600 ac. and by A.D. 700 more than 1,800 ac. It is on open ground and had no city walls. Large temples and palaces formed the nucleus of the city; the largest temple pyramid now stands 212 ft. high, without the temple itself, which has disappeared. In the residential sections buildings were densely clustered. Streets and plazas were paved with lime plaster, and there was a complete underground system of drainage. This metropolis was violently destroyed, some time between the 8th and the 10th centuries, and never rebuilt.

After the fall of Teotihuacán came the period of Tollan, the capital of the historic Toltecs. Its ruins are located in the outskirts of modern Tula, state of Hidalgo. Systematic excavations of the ceremonial centre at this site were begun in 1940. Notwithstanding the aureole of greatness surrounding the Toltec metropolis in the Aztec sagas, the remains are far less impressive than Teotihuacán. The Toltec period lasted from the 10th century to the end of the 12th or beginning of the 13th.

The period of the Chichimec (barbarian) invasions and the rise of the Aztecs of Tenochtitlán (founded in the 14th century) followed. Whereas there is copious historical information for these periods, comparatively little systematic excavations have been done to link archaeology and history.

Oaxaca.—The excavations at Monte Albán, one of the largest sites in all Mesoamerica, located on top of a hill which rises 1,200 ft. above the central valleys of Oaxaca, have revealed a long occupation of this place, first as a ceremonial and residential centre and later as a cemetery. The sequence has been divided into five periods or phases named Monte Albán I to V, the third subdivided into two subphases (a and b). Monumental stone building began in MA I and reached its peak in MA IIIa times, when the whole top of the hill and the northern slopes were covered with temples and residences. Burial chambers, some of them decorated with mural paintings, are found under their floors. At the end of MA IIIb the place was abandoned and the buildings fell into ruin. Subsequently Monte Albán was used only as a burial ground. The phases MA IV and V, perhaps partially contemporaneous, are defined on the basis of the material found in these burials. Tomb 7, a funerary chamber built and used in the MA III period, was reused in MA V times for the burial of

a lord and his retainers, with jewels of gold, silver, jade, turquoise, pearls and other materials.

It is noteworthy that since MA I, although possibly toward its end, there is evidence for a numerical system, hieroglyphic writing and calendar, perhaps the oldest in Mesoamerica. Also, a number of stone carvings belonging to the phase MA II have been interpreted as meaning "conquest" of different unidentified places by the people of Monte Albán. If this is true, these glyphs would be the oldest evidence of wars of conquest known to date in the same area. Although artificial fortifications protecting Monte Albán have not been recognized, its location in a strong defensible position is unusual, for most of the Mesoamerican settlements of comparative age were situated in open ground, with obvious disregard for defense. However, the selection of hilltops for settlement appears to have been frequent from the earliest periods in the mountainous Mixtec region, to the west of Monte Albán.

Outside Monte Albán, its earliest phase is represented at Monte Negro, near Tilantongo. MA IIIa has been found at Yucuñudahui, near Chachoapan, and MA V—associated with a hilt of a 16th-century Spanish sword—at the neighbouring Las Pilitas. Another MA V site is Inguiteria, near Coixtlahuaca, where evidence of Aztec occupation has been found. It is historically known that the Aztecs conquered Coixtlahuaca about 1460.

Radiocarbon dating for beams of a collapsed roof of Tilantongo (MA I) yielded 650 B.C.; for beams in a tomb of Yucuñudahui (MA IIIa), A.D. 300. Cross dating with other regions makes it possible to date the beginnings of MA IV about the 10th century, and there is ample evidence that MA V lasted to the Spanish conquest.

Guatemalan Highlands and Pacific Coast; El Salvador.—At Kaminaljuyú (a very large site situated in the outskirts of Guatemala City) and neighbouring places of the highlands, a continuous sequence has been established which covers the time from Archaic agricultural communities to the Spanish conquest. It has been divided into three main periods, subdivided into phases as follows: Pre-Classic period—Las Charcas, Arevalo, Majadas, Providencia, Miraflores, Arenal and Santa Clara; Classic period—Aurora, Esperanza, Amatle and Pamplona; Post-Classic period—Ayampuc and Chinautla. Kaminaljuyú itself was abandoned at the end of the Classic period.

The Las Charcas phase is represented by the findings made in rectangular or bottle-shaped pits with small top openings, dug deep into the subsoil for storage or other purposes (some of them contained burials), and in irregular excavations (possibly dug to obtain material for building) filled with trash. There is evidence for maize, polished greenstone celts, excellent pottery, textiles, terra-cotta figurines (human and monkey effigies) and flat and cylindrical clay stamps, as testimonies of a sedentary way of life of long-standing tradition. In the following Arevalo phase monumental building (earth mounds) began at Kaminaljuyú, and during the Miraflores phase one of the largest mounds of this site was built. It developed from a small platform, about 6½ ft. high, through six major reconstructions and several minor additions, to a stepped pyramid more than 65 ft. high, covered with mud plaster. Two burial chambers have been discovered near the top. Several bodies were found in each chamber, masters—who had been lying extended on a low wooden platform in the centre of the tomb—and their retinue. Funerary furniture includes hundreds of fine pottery vessels, shell, bone and jade ornaments, mushroom-shaped stones of unknown use, and a pyrite mosaic mirror.

A burial mound at Finca Arizona, near San José, on the Pacific coast, belongs to the Arenal phase. Unlike the mound of Kaminaljuyú just described, the tumulus of Finca Arizona lacks burial chambers. It grew through successive additions of earth platforms. Upon each one of the platforms there were several bodies and the offerings. The ruins at El Sitio, near Ayutla, on the Mexican border, also belong to this phase. There are many mounds formally arranged around plazas and plain monuments of columnar basalt. Urn burials are a feature of this site and at the neighbouring El Jobo.

During the Esperanza phase of the Classic period strong influences from central Mexico, emanating without doubt from Teotihuacán, were felt throughout the whole area. At Kaminaljuyú the identity with Teotihuacán is so great—in what refers to ideology and style—that a colonization at the aristocratic level has been postulated. At Kaminaljuyú itself this phase is represented mainly by the contents of a dozen tombs found beneath two mounds. The tombs were beam-roofed chambers. The earliest ones were covered by low platforms, the later ones by pyramidal or stepped pyramidal structures with stairways on one side and one-room temples on the summit. These funerary monuments were rebuilt each time a new tomb was made, so that a number of superimpositions resulted. Most, if not all, of the tombs were built for the interment of important adult males with slaves or concubines—generally adolescents 13–17 years old—sacrificed to accompany their masters. In three of the tombs the suite included a dog. In others, instead of complete skeletons of retainers, only the skulls with lower jaws were found, evidence of ceremonial beheading. In some cases, the main occupant was sitting on a wooden litter or box. The furniture includes always a milling stone and a variety of fine pottery vessels, jade and shell ornaments and pyrite mosaic mirrors, and there are traces of objects of perishable materials, such as cloth and feathers, but not of the products of metallurgy.

In late Classic times metallurgy appears for the first time, the metal objects (of gold-copper alloy) being quite certainly imports. Technique and style point to Panamá as the place of origin. The earliest were found in a burial at Tazumal, near Chalchuapa, western El Salvador, and are datable at about A.D. 750.

The Post-Classic period, represented by findings made in other highland sites, is characterized by late Mexican influences detectable in monumental architecture and burial customs (cremation instead of inhumation), attributable to invasions recorded by the native tradition. These were earlier, however, than the expansion of the Aztec empire, which only reached the present Mexico-Guatemala border at Ayutla about 1500 and did not push beyond. Also, there was a change in settlement pattern; whereas earlier sites were generally established on open ground and lacking artificial defenses, Post-Classic sites are for the most part situated on mesas surrounded by ravines and further protected by stone walls. Sites such as Utatlan, capital of the Quiché, or Iximché, capital of the Cakchiquel, are examples of such castle towns.

The beginnings of the Pre-Classic period may go back to before 1000 B.C., as does the Archaic period of central Mexico. Cross dating with the central Maya region makes it possible to date the Classic period from before A.D. 300 to A.D. 900. The Post-Classic period ended with the Spanish conquest.

Central Maya Area.—This area includes the foothills and the lowlands between the Chiapas-Guatemalan highlands and the parallel 18° 30′ N., from Comalcalco (Tabasco, Mex.) to Copán (Honduras). Occupation at Uaxactún (Petén, Guat.) by sedentary pottery makers began at an undetermined date, although certainly earlier than the beginning of the Christian era, and the site was abandoned in the 10th century A.D. The sequence of phases at Uaxactún is generally used as a standard for the whole area. For the last 600 years of this continuous sequence, it may be tied with the Long Count dates of the inscriptions. Unfortunately, the correspondence of dates expressed in this system of reckoning time and our calendar has not been securely established. For the Christian equivalent of the Maya Long Count dates given in this article the Thompson correlation, accepted by a majority of specialists, has been used.

The oldest remains at Uaxactún (termed Mamom phase) were found in the black earth under the earliest pavements, only in a restricted area of the site, indicating a small settlement. No milling stones have been found in this deposit. This absence perhaps indicates that maize was not cultivated yet. Instead starchy roots and tubers may have been the staple food plants cultivated at this time. Rare obsidian tools and jade indicate a little trade with the highlands, for these materials are not found in Petén. Alignments of rough stones may indicate garden plot boundaries or the remains of retaining walls for house

platforms. Burials were simple interments. The pottery and hand-modeled terra-cotta figurines belong to the generalized archaic Mesoamerican pattern.

A stepped platform (Temple E-VII-sub), decorated with grotesque stucco masks, is the oldest monumental building known to date at Uaxactún or at any other site in the central Maya region. It is dated in the following Chicanel phase, which ended in the second half of the 3d century A.D.

From about A.D. 300 to about A.D. 900 (phases Tzakol, to 600, and Tepeu, to the end) a refined civilization, superimposed on the elements of a peasant culture, flourished over all the area. Besides Uaxactún, sites worth mentioning are Palenque, Bonampak, Yaxchilán, Piedras Negras, Tikal, Holmul, Quiriguá and Copán. Tikal (in central Petén, near Uaxactún) was the largest and possibly the oldest of these centres. The civic and religious nucleus covers about 500 ac., and the suburbs extended a long distance. This civilization is characterized by monumental stone architecture for temples and palaces, with rooms roofed with corbeled vaults; elaborate tombs; artistic climax in sculpture, painting and the minor arts; hieroglyphic writing; highly developed arithmetic, astronomy and calendar. The tallest building is Temple IV at Tikal, 229 ft. high from the base of the stepped pyramid to the pinnacle of the roof. Burial customs for the upper class are exemplified by the crypt found in 1952 under the Temple of the Inscriptions, at Palenque. A hidden stairway leads to a vaulted chamber, where the corpse of some personage was buried in a sarcophagus. Six adolescents lay guarding the entrance to the chamber.

From A.D. 800 to 950, one after another of the centres of this civilization were abandoned and fell into ruin. Then the central Maya seem to have reverted to a pattern of peasant communities. There are only scanty archaeological data for the following period.

Northern Maya Area.—This region is formed by the peninsula of Yucatán, north of the parallel 18° 30′. Archaeological surveys in the 1940s showed that, contrary to a formerly widespread misconception, this area had a well-distributed and probably dense population of sedentary farmers as early as the central Maya region. There was also a cultural florescence comparable and contemporary with the Classic Maya civilization of Petén and adjacent regions. The chronological outline stands as follows: Formative period (subdivided into Early, Middle and Late), beginning at a still undetermined date and ending at about A.D. 300; Yucatán Regional and Florescent periods, corresponding to Tzakol and Tepeu of the central area (4th to 10th centuries); Toltec period (Chichén-Itzá, 987–1204); Post-Toltec period, subdivided into Mayapán phase (1204–1460) and a last phase, archaeologically ill-defined, from the fall of Mayapán to the Spanish conquest (1540). From 1204 onward, the strong alien influences which characterize the Chichén phase vanished, and the introduced ideas disappeared or were integrated into the traditional Maya cultural pattern.

The beginnings of monumental architecture may date from Middle Formative times at Santa Rosa Xtampak, and to the Late Formative phase belongs a large raised terrace with several buildings on it, at Yaxuná. A Long Count date, carved on a stone lintel at Oxkintok, corresponds to A.D. 475—the earliest inscription yet found in Yucatán by the 1950s. At the same time, good stone masonry, resembling closely the characteristics of the early Tzakol style of the central region, and the corbeled vault were already in use. Cobá, where a number of steles carved in pure Petén style record dates ranging from 623 to 732, was the centre of a net of radiating causeways, the longest one—to Yaxuná—62 mi. long. These causeways, running generally in a direct straight line, are raised above ground level, have rubble cores held by stone retaining walls, and the surface—which has slight camber—was packed hard with stone rollers. One of these road rollers is still to be seen near the Yaxuná causeway. Four distinct regional styles of monumental architecture are distinguishable for the Yucatán Florescent phase. They are characterized by differences in the baroque decoration of the façades. Some typical sites are Río Bec, Xpujil, Etzná-Tixmucuy, Uxmal, Labná and old Chichén. Chacchob also belongs to this phase; it is surrounded by a stone wall enclosing an oval area roughly 550 by 380 yds. This marks a change from open to fortified towns.

Chichén-Itzá, the political capital of northern Yucatán in the following period, shows strong Toltec influences in monumental architecture, sculpture and ideology. In the Cenote of Sacrifice (a large natural well) metal objects imported from Panamá have been found and also sheet gold disks—quite certainly imported as such—on which Itzá artists embossed scenes depicting the subjugation of the native population by these invaders Mayapán, which succeeded Chichén in the supremacy, was a walled city. The wall encompasses an area of more than 1,000 ac., and the suburbs extended for some distance beyond.

The Gulf Coast.—The earliest occupation of the Olmec area of southern Veracruz and western Tabasco is represented by pottery vessels and figurines found in the lower levels of the excavations at Tres Zapotes (southern Veracruz). They belong to an early lowland pottery pattern also found in Petén and in the Ulúa valley. The relationships with the Archaic periods of the highlands are fewer. The Middle Tres Zapotes phase is correlated in time with the horizon marked by the expansion of Teotihuacán influences and by the Tzakol phase of Uaxactún (A.D. 300–600). The occupation of La Venta, in the swamps of western Tabasco, is also assigned to this period. La Venta is regarded as the type site of the florescent Olmec culture. It was a site of ceremonial character, not a large centre of population; people settled in small hamlets scattered around this nucleus. These hamlets changed location frequently, as is characteristic in most tropical rain-forest areas of the world. La Venta, as well as the other centres of the Olmec culture, is famous for impressive stone sculptures of a refined style; noteworthy among them are colossal human heads. The continuous occupation of Tres Zapotes came to an end at about A.D. 1000. Later, the site was reoccupied for a short period and abandoned again before the arrival of the Spaniards. A carved stele at Tres Zapotes bears a date which, if expressed in the Maya Long Count system, would correspond to 31 B.C. However, it is doubtful that the starting point of the Olmec calendar was the same as that of the Maya Long Count.

In central Veracruz the ruins of Cempoala are well known. It was a southern Totonac capital where Hernán Córtez stayed at the beginning of the conquest of Mexico. To the north, the ruins of El Tajín, near Papantla, are outstanding from the viewpoint of architecture. It seems that the great period of construction at El Tajín falls between A.D. 600 and 900.

Western Mexico.—This archaeological province includes the present states of Michoacán, Jalisco, Colima, southern Nayarit and southern Guanajuato. More or less complete local sequences have been worked out for a number of zones in this area, but their mutual correlations and those with the other major Mesoamerican regions are insufficiently understood. It is not possible to draw a comprehensive picture of the archaeology of this area. However, two aspects of it are worth mentioning. One is the extraordinary ceramic statuary of Colima, Jalisco and southern Nayarit. The artists who modeled these small, baked clay sculptures portrayed, frequently with jovial irony, scenes of everyday life; the figures were deposited in tombs as if to continue in the mansion of the dead the routines of life on earth. The ethnographical data provided by these sculptures reflect a culture markedly divergent, in many aspects, from the rest of Mesoamerica. The other aspect deserving mention is metallurgy. The metal objects from this area in museum and private collections and the findings made in excavations at Tzintzuntzan (a historical Tarascan capital) Cojumatlán, Apatzingán and Tuxcacuesco (where metal items appear only in the upper levels, shortly before the Spanish conquest) show technical and stylistic differences from the metallurgical traditions of other Mesoamerican regions. It is probable that west Mexican metallurgy originated independently from the rest of Mesoamerica. From the viewpoint of techniques it exhibits similarities with the pre-Columbian metallurgy of Ecuador and the north coast of Peru. Also the abundance of implements such as blades for digging tools, axes, awls and fishhooks is exceptional in Mesoamerica. Findings in the southwestern United States, dated

from the 10th century A.D. onward, of copper bells quite certainly made in western Mexico set a minimum date for the beginnings of west Mexican metallurgy.

The Northern Frontier.—At Pánuco, in the Huasteca region of northern Veracruz, a long continuous sequence has been discovered. It has been correlated with the sequence for central Mexico, from early Archaic times to the Spanish conquest. In late periods (after the 10th century) Huasteca influence extended northward to the Río Grande delta. However, earlier Mesoamerican influences are discernible in the archaeology of the lower Mississippi basin; the nature of the contacts and the route of diffusion are not clear, however.

In the central section of this frontier, there is archaeological evidence that territories formerly occupied by sedentary farmers were abandoned at the time of the fall of Tollan and taken over by nomadic hunters. La Quemada, in the state of Zacatecas, was a castle town situated on a hill surrounded by cliffs and further protected by stone walls; a network of causeways linked the acropolis with a constellation of small villages scattered all over a fertile valley. La Quemada was burned down before the arrival of the Spaniards. This site is of special interest because it is located at the entrance of one of the corridors of communication between the civilizations of Mesoamerica and the aboriginal cultures of the southwestern United States, the one following the piedmont of the western Sierra Madre. There is a gap between the northernmost Mesoamerican settlement in this direction (Zape, in the state of Durango) and the southward extension of the southwestern cultures (Casas Grandes, Chihuahua). However, there is evidence for some trade along this corridor.

The other corridor linking Mesoamerica and the southwest was along the coastal plains of northern Nayarit, Sinaloa and southern Sonora. This was an area culturally marginal to Mesoamerica, although strong influences emanating from central Mexico were felt there during Toltec times. The excavations in this area have failed to reveal any evidences of occupation debatable before the 9th century A.D. However, earlier Mesoamerican influences reached the Hohokam area of southern Arizona, seemingly through this corridor.

XIX. ANGLO-AMERICA

Although human history in the Americas is reckoned in thousands of years (*see* sec. XVI, above), Anglo-American archaeology is concerned here with the period between 4000 B.C. and A.D. 1800. Usually, Anglo-America includes only the area north of the international boundary, but the northern tier of Mexican states falls archaeologically within Anglo-America. The 6,000-year span of time covered here encompasses all the American Indian story, from climax to near extinction. During this period the population density of the continent increased a thousandfold.

The physical appearance of the very earliest Americans has not yet been learned, but the physical type in 4000 B.C. is known to have differed from the Indian types of Columbus' time. The population of all Anglo-America evidently was derived from Eurasia. Even though the physical affiliation of much of the prehistoric population is Mongoloid, E. A. Hooton and others, in the 1920s, demonstrated that other racial elements could be recognized. This polyhybrid nature of the American Indian was long interpreted as evidence of successive immigration of different physical stocks into North America, with subsequent hybridization occurring in the Americas. The extent to which identifying physical traits had been submerged by Mongoloid physical traits was regarded as a measure of the passage of time, the Mongoloids being regarded as the latest arrivals on the American continent. J. B. Birdsell in 1950 and George Neumann in 1952, in entirely different studies, demonstrated that in the first arrivals the Mongoloid physical traits are conspicuously lacking. The wide diversity of physical type seen among the American Indians comes many years later than 4000 B.C. (*see* INDIAN, NORTH AMERICAN).

Development of Techniques.—It is necessary to mention that Anglo-American archaeology has moved away from antiquarianism (with neither problems nor perspective) only after 1930. An exception is the restricted and specialized area of the American southwest, where there were 50 years of intensive but disorganized work by A. F. A. Bandelier, E. L. Hewett and Byron Cummings, before N. C. Nelson, A. V. Kidder and A. L. Kroeber in the early 1920s developed a systematic attack upon the problems. Refinement of the archaeology of the southwest had resulted by 1950 from the work of Earl H. Morris, Frank H. H. Roberts, Jr., Harold Gladwin, Emil Haury, J. O. Brew, Paul Martin and Erik Reed.

Study of the earthworks in the eastern half of the continent began much earlier, however. In fact, Thomas Jefferson excavated an earthen mound and reported his findings. The important figures in the early stages of earth mound exploration between 1840 and 1920 were such men as E. G. Squier and E. H. Davis, T. H. Lewis, Cyrus Thomas, J. W. Powell, Gerard Fowke, C. B. Moore and William H. Holmes. Even so, until 1930, all Anglo-American archaeological data were chaotic and discrete. Writing was descriptive; the technique of comparison with other sites, distant or adjacent, was not yet developed. Stratigraphy, upon which relative chronology is based, was not often observed; if observed, it was ignored in interpretation. Field techniques were far from adequate. The reports are concerned with the "vanished race of giants" or "lost arts" or "lost tribes," rather than with cultural connections or time-space relationships.

In the 1930s, however, a scheme of classification called the midwestern taxonomic system was devised. Will C. McKern is credited with the major work on the idea. This scheme operated much like the zoologists' classification, with the sole and expressed objective of establishing degrees of similarity between collections of archaeological remains. Time-space problems were explicitly ignored; but from the relationships discovered, time and space relationships developed. The system was espoused by all leaders in eastern and midwestern archaeological study, and amazingly fast progress in the organizing of all archaeological material resulted from its use. Scientific progress, however, was only partly in classification; the techniques of digging and recording were tremendously improved after 1930; Carl Guthe and Fay-Cooper Cole were entirely responsible for this improvement. Excavators became conscious of the importance of exact records. Notice of stratigraphy; the segregation of specimens by precise provenience; preparation of maps, sketches and photographs; and other precautions were made routine excavation techniques. Greater technical precision resulted in fuller information; more precision in analysis was therefore possible. By 1950 it was possible to say that archaeological technique was more advanced than archaeological interpretation.

Anglo-American archaeology thus moved through three distinct phases: first, it can be characterized as antiquarian or romantic with a "flat" prehistoric landscape, with data chaotic until the 1920s. Next, systematic and improved techniques began to interest scholars by 1930. Thereafter date classification of data and the development of regional chronologies progressed, alongside the increased recognition and improved description of prehistoric cultures. Finally, it became possible in the 1940s to undertake synthesis of the regional data. This concern with synthesis—the third phase—marks the beginnings of maturity for Anglo-American archaeology; synthesis raises the study to the level of science. The work of men such as Alex D. Krieger with problems of the correlation of regional data and of continental, hemispheric and world-wide relationships was significant. Archaeology, from 1950 onward, increasingly contributed specific data for use in general anthropology.

The chronological bases upon which this section rests are varied

Stratigraphy, the principle of superposition, is, of course, primary; where available, dates derived from radiocarbon, from tree rings and from native or European documents are utilized.

Regional Divisions.—Students recognize several broad regions or cultural provinces within Anglo-America. These are the arctic, northeast, southeast, northern Mississippi valley, plains, southwest and coast-basin areas. These seven broad geographical areas (*see* Table II) are particularly useful in working with the more recent cultures. For convenience the regional treatment will be used here.

It is emphasized that the quantity and quality of archaeological information varies tremendously from region to region. In the southwest data are abundant; in the west coast-basin province they are disappointingly scanty for the period of interest. A very uneven treatment here reflects, as nothing else could, the incomplete status of Anglo-American study. Analysis here begins with the oldest remains and comes forward to recent times. It is emphasized that the cultural designations—Archaic, Woodland, etc. (*see* Table II)—are quite imprecise; they carry, unfortunately, both chronological and cultural implications. The reader cannot escape the awkwardness of poor nomenclature which has developed; he can only be warned about it.

Archaic.—Over the entire continent (uncertain in the arctic) there existed a culture called the Archaic. In a variety of forms, and divided into early and late phases, the Archaic is reported from nearly every state, but it is best represented in the northeast and southeast areas.

A typical Archaic site is Indian Knoll on Green river in Kentucky. This site is a deep, extensive shell-heap midden 250 ft. by 500 ft., marking the site of a long-used camp. Abundant river mussels were the staple food, rich and easily collected. There C. B. Moore (1915) and William S. Webb (1946) recovered more than 1,100 skeletons and 20,000 objects of flint, bone and shell of aboriginal manufacture.

The Archaic level of living was low, a hunting and gathering pattern, completely parasitic and dependent upon the environment. Subsistence was geared to natural resources; there was no domestication of plants or animals (except the dog). Not even pottery was known. Although communities were small, they were reasonably stable. At least, favourable shellfish localities were obviously occupied for long-continued periods, abandoned and then reoccupied. The shell heaps, however, also yield tons of broken animal bones, including dozens of species not now eaten, along with the deer; the latter usually predominated in the forest animal diet. The many nuts, berries and tubers were harvested and used in season. The domestic dog was present; evidently dogs were even of religious or ceremonial importance because many dog skeletons, buried with great care, are found. Burials—both human and dog—were made in the village middens. Usually a deep round shaft or well was sunk into the debris, and there the dead were placed; the body was in a tightly flexed position, knees to chest. Infrequently tools and ornaments of bone, stone or shell were placed with the dead. No dwellings were found, although there is evidence hinting that flimsy circular or crescentic windbreaks, floored with hard-packed clay, were built. Presumably skins served for clothing. In technology the culture was simple. Tools, weapons and ornaments were simple but specialized; their fabrications took considerable skill and patience. The list of material possessions which survive for the archaeologist to recover includes the atlatl or spear thrower, netting, basketry, shallow stone mortars with pestles, awls, needles, scrapers, chisels, fishhooks and chipping tools, all made of bone and antler, nut-cracking stones (small slabs with many shallow cups on one or both faces), beads of marine and fresh-water shell, chipped stone knives, arrow or lance points and drills; scrapers and choppers were numerous, as were hammerstones. Flint objects were usually large. Chipping was usually bold, done by percussion.

In the late Archaic new items were added to the inventory of artifacts. Among these are polished stone celts (an ungrooved ax form) and grooved axes, atlatl weights (called boatstones or bannerstones), tubular pipes and stone bowls (steatite or sandstone). James B. Griffin states that the centre for the polished stone complex appears to be in the northern Mississippi valley. Barbed bone harpoons and polished slate knives, on the other hand, are a special characteristic of the Laurentian culture of New York. Copper objects—made of native free copper—were much used by Late Archaic peoples in the Lake Superior region. These latter objects were widely traded.

It must be realized the above descriptive material applies essentially to sites in the southeast. Local cultures—somewhat variant from this pattern but closely comparable or identical in orientation and level of achievement—have been discovered from coast to coast. Further, the time of local occurrence varied greatly. For example, Early Archaic in New York (Lamoka site) has a date of about 3500 B.C. Early Indian Knoll is also dated at about 3500 B.C. Dates for Archaic sites farther south tend to be younger. The Archaic culture is generally believed to have developed in the northeast and spread to the rest of the country; but in the coast-basin province the same levels of culture, comparable life ways and comparable artifacts are reported at a date much earlier than 2000 B.C.

TABLE II.—*Chronological Relationships of the Broad Cultural Divisions of Anglo-American Archaeology*

Period	Arctic	Northeast	Southeast	Northern Mississippi valley	Plains	Southwest	Coast basin
A.D. 1800						Fusion	
A.D. 1000	Eskimo	Late Woodland and Late Mississippi	Late Mississippi Middle Woodland Early Mississippi	Mississippi and Late Woodland	Mississippi Mississippi and Woodland blend	Florescent Formative Elementary	Persistent Desert culture base akin to Archaic
A.D. 1	Birnirk	Woodland (Middle)	Woodland (Early)	Woodland (Middle)	Woodland (Middle) Woodland (Early)		
1000 B.C.	Dorset	Woodland (Early)		Woodland (Early) Archaic (Late)			
2000 B.C.	Pre-Aleut	Archaic (Late)	Archaic (Late)			Desert	
3000 B.C.			Archaic (Early)	Archaic (Early)	Archaic		Desert
4000 B.C.		Archaic (Early)					

There are geological reasons for the concentration of the Archaic east of the Mississippi river. The entire west, as well as the plains, was subject to long, recurrent droughts, from 5000 B.C. to about the 1st century A.D., and to lesser ones since then. At the same time the woodlands of the east were relatively well watered. Drought conditions, and all that these imply, readily explain the less abundant Archaic remains outside the east.

What happened to the Archaic peoples? The culture itself merely changed, as do all life ways with the passing of centuries; the old way was simply lost. For example, Joffre L. Coe

believed that in North Carolina he could demonstrate archaeologically a continuous flow of culture from Late Archaic until historic times. Again, the marginal Algonkian-speaking tribes of the northeast possessed a culture which preserved many traits of the Late Archaic life way. The physical type of the population itself also persists; typical examples of the earliest American physical type can be found in living populations.

Early Woodland.—The Archaic period ends more by definition than at a specified time. Thus, when pottery is introduced or added to Archaic material culture, the Woodland culture is at hand. The traits of the early Woodland culture include most of those recorded for the Archaic, but by 1000 B.C. two important additions—mound burial and pottery—gave an altogether new complexion to the culture. The tubular smoking pipe was present by this time. Maize agriculture is believed by some to be this old in the northeast.

The Woodland pottery, as McKern pointed out in 1937, is an importation from Asia. It is coarse and rough, built by the coil process, usually of simple flowerpot form or possessing a conoidal base and slightly flared mouth. There were granules of crushed rock or coarse sand—called temper—mixed with the clay. The surfaces of the pottery were either plain or marked with the imprints of cord wrapped around paddles. In the southeast the first pottery was plain and had a fibre—grass or moss—temper.

The burial mounds are nothing but low heaps of earth. Bodies were placed under the mound and in pits later dug into the earth fill of the mound. Burials might also be laid on the surface of the first mound and covered over; thus mounds grew larger through accretions or additions. Burials were most often made in the flexed position.

Much local diversity exists in Early Woodland culture, and the range in time is very great. The northeastern material is older, by from 1,000 to 2,000 years, than material from southeastern sites of a comparable cultural level. In the plains Early Woodland exists, but had not, by the 1950s, been described with any certainty. Nothing comparable in form to Early Woodland exists in the southwest or coast-basin areas. The Adena culture of Kentucky and Ohio has been long regarded as being of Early Woodland age; in 1950 this placement became a subject of controversy. In effect, the Early Woodland stage constitutes a formative or transition stage into the richer Middle Woodland phases.

Middle Woodland.—Middle Woodland, best represented in the Ohio valley, probably developed there. For all practical purposes, the spectacular Hopewell culture, with its widely scattered variants, is the Middle Woodland. The age in Ohio of the climax phases falls from 200 B.C. to A.D. 1. In the southeast and eastern plains the age is markedly younger. In Middle Woodland, the cultural accretions to earlier forms include agriculture (maize, beans) and the enormous earthen burial mounds where prominent personages were buried with rich grave furnishings and much ceremony. The inventory of artifacts becomes rich and varied; an extensive trade over the northeast, southeast and plains testifies to a strong, wealthy and dominant culture which affected the eastern two-thirds of aboriginal Anglo-America for 1,000 years. In many fields the Hopewell people achieved technological artistry exceeding that later reached in the southeast and southwest.

The hallmark of this richly ceremonial culture is in the grave furniture, the extensive earthwork enclosures and the huge artificial mounds. These earthen mounds were erected, basket load after load, over large, criblike log tombs or subfloor pits; the tombs or pits contained important dead, usually laid down supine at full length. With the dead were artifacts of great beauty. Strings of river mussel pearls, fragile fanciful ornaments of sheet mica, enormous obsidian blades, scores of tools and ornaments of copper, beads and pins from both Gulf coast and Atlantic coast shells, beautiful pottery of varied form, grizzly bear teeth and claws, carved and polished stone including specialized effigy-type pipes and countless other items which are today *objets d'art*. The ceremonial pottery is easy to recognize; it appears wherever Hopewell influence reached and is used as an index marker for the culture. Although these people were numerous and had large villages, the elaborateness of the Hopewell ceremonials has blinded the eyes of investigators to the rest of the life way. Little of the "common" was known in the 1950s, but research was correcting this condition.

The Adena culture is related to the Hopewell; whether it is an ancestral form or a later, perhaps weakened or decadent one is controversial. Radiocarbon dates, however, place the Adena many centuries later than the major Hopewell sites. The effigy mounds of Iowa and Wisconsin are to be considered Middle Woodland, but appear to be as late as A.D. 800 or 900.

Late Woodland.—Middle Woodland marks the climax of the Woodland way; neither in geographic dominion nor artistry did the Late Woodland keep up the standard. In the entire southeast, the Late Woodland culture is even lacking or exists as scattered survivals; in rather subdued form it persisted in the northern Mississippi valley and northeast to be finally identified with the historic tribes of the eastern woodlands of the United States and Canada. In fact, the name Woodland was applied to the archaeological material because of its similarity to the material culture of these historic Woodland tribes. The Iroquois, Algonkin and indeed all the east coast tribes represent the end product of the Woodland way.

Mississippi Cultures.—Some time after A.D. 1 (the exact date is very controversial) Woodland dominance waned in the southeast. Probably between A.D. 500 and 800, coincident with or slightly earlier than the development of the high southwest cultures, the so-called Temple Mound or Mississippi culture arose, eventually to achieve a fabulous richness. For practical purposes the presence of truncated pyramidal earthen mounds of varying size mark the culture. These mounds were substructures for temples and priestly dwellings. The sites are found only in the rich river lands; maize farming was the subsistence base and permitted large populations with ample leisure for public works. The farmers were subservient to priest-rulers who dominated from sacred temple towns. The culture, containing Mexican elements from the beginning, apparently developed in the area just south of the confluence of the Ohio and Mississippi rivers; from there its influence spread up the Missouri river into the plains, over all the southeast and much of the northern Mississippi valley. Just how and by what route the continuing Mexican culture elements reached this part of Anglo-America is a controversial subject. In its early forms, the Mississippi culture was not especially spectacular; the climax is the later phase.

It is important to realize that the culture was flourishing or perhaps just passing its zenith when America was discovered in 1492. The De Soto chroniclers clearly, and often in detail, describe a living Mississippi culture type.

Scores upon scores of Mississippi sites have been dug. The remains are complex and rich. Large mounds, often in groups surrounding a plaza, formed the nuclei of large settlement areas; support was derived from adjacent farm villages. In general, art technology, religion, trade and government were all well developed. In pottery, from earliest times, great skill and artistry are seen. New vessel shapes—bowls, bottles, plates, effigies, etc.—replaced the simple Woodland forms, but seem to have been much influenced by Middle Woodland external decoration trends. Temper was often crushed shell. Painting of pottery was common. From stone, wood, shell and copper, tools and ornaments were made. Technology and art reached a climax in the southern cult—a rich, flamboyant assemblage of shell, copper, mica and stone specimens, strongly reminiscent of Valley of Mexico splendour. The Mississippi culture waned rapidly after the arrival of Europeans, but survived in weakened form until extinction or removal of the historic tribes of the southern states.

In the plains after A.D. 800 to 1000 a series of cultures, very similar to one another, in which Woodland and Mississippi elements blend, bespeak a large population with a wide area of dominance. The plains cultures are under intensive study. Generally they are characterized by village settlement, the earth lodge, practice of both horticulture and hunting, and distinctive ceramic tradition. Mounds were not built. The understanding of their intraregional and interregional relationships is crucial to full understanding of American prehistory.

Southwest.—The American southwest—locus of the Hohokam and Pueblo cultures—has been the scene of intensive archaeological work. The southwestern cultures are thought by some to have achieved the highest level of complexity found north of Mexico, although the Late Mississippi cultures vie for this honour. It must be pointed out that the glory of the Pueblo southwest was both recent and short-lived, falling between A.D. 700 and A.D. 1300. The greatest cultural virility and density of population appear to have fallen between the years A.D. 850 and A.D. 1050. Thereafter the population strength and geographic domination of the ultraconservative Pueblo way steadily declined until by the 1950s the entire Pueblo population numbered only a few hundred in northern Arizona and along the waters of the Rio Grande.

The Pueblo culture has two recognized regional centres—the Anasazi (four-corners area) and the Mogollon. Of the two the Anasazi is the more colourful and is here described. Hiroshi Daifuku in 1952 divided the history of the southwest into four meaningful periods, each with time and culture connotations: the Elementary stage (3000 B.C. to A.D. 1), the Formative (A.D. 1 to 700), the Florescence (700 to 1300) and the Fusion (1300 to 1700). The Elementary stage refers to an essentially Archaic pattern—the Desert culture which dates back to 9000 or 10,000 B.C.—which served as a base for the Pueblo. From the Desert culture—a nomadic, hunting-gathering life geared especially to a varyingly hostile, semidesert country—the southwestern high cultures developed. The Formative stage of development from the Desert base contains the seeds of all later specialization. It is early (A.D. 1 to 300) characterized by semisubterranean dwellings, subsistence on both wild foods and cultivated corn, domesticated dogs and great skill in textile work (plant fibres, hair and fur). Later (A.D. 300 to 700), stone was used in more elaborate pit-house construction, and agriculture—new varieties of corn and beans—pottery, turkey-feather textiles, bow and arrow, the village pattern and a strong sense of religion were added. Thus the Pueblo way was established. All subsequent additions to the culture complex were rooted in the Formative (also called Basket Maker). During the Florescence (also called Developmental and Great Pueblo periods) houses above ground, made of coursed masonry with stones set in mud mortar, culminated in the towers of Mesa Verde or the 800 rooms of Pueblo Bonito in Chaco canyon. Crude gray pottery developed into the flamboyant black on whites and polychromes of Mesa Verde and Kayenta. Agriculture became the chief source of food and allowed the leisure for arts and crafts to become varied and specialized. Cotton was added to the resources for textiles; the pit house evolved into the specialized kiva or ceremonial chamber, still used by the remnant Pueblo population. Religion, concerned with weather and food crops, became very complex and paramount in cultural importance. The social unit shifted from family to the clan and finally to the town. The turkey was domesticated; turquoise, alabaster and marine shells were used for personal ornament. In short, there was exuberant elaboration in technology, architecture and religion.

Then came the dismal years of 1273–99. A great drought and the presumed pressure of enemy (Navaho and Apache) peoples led to the abrupt dispersal and shrinking of the Anasazi. In turn came the migrations and population pressures of the period of Fusion. After 1300—the start of the period of Fusion—the evidences of interchange of ideas, migration and mixing of people and local variations of culture all over the southwest are legion. The Salado, the Patayan and the Sinagua are some of the local developments.

The Mogollon variant of Pueblo culture is somewhat earlier, and ancestral perhaps to the Anasazi. For example, Paul Martin reports plain undecorated pottery by A.D. 1. Although its developmental history generally parallels the Anasazi, it never became so fully dependent upon agriculture nor was it ever so flamboyant in technology, nor did the large urban centres grow up.

The Hohokam culture of southern Arizona can be divided into about the same cultural phases, but in general these phases are consistently 200 or 300 years older than comparable Pueblo manifestations. The Hohokam are noted particularly for their markedly different ceramic tradition, their consistent preference for cremation of the dead, jacal (stick and mud) houses, and for the extensive irrigation systems developed along the Salt and Gila rivers. Stone masonry, black-on-white pottery and a strongly formalized religion never interested these folk until after A.D. 1200, when Pueblo ideas reached them from the north.

Arctic.—The archaeology of the arctic was only in its beginning stages at mid-20th century. Aside from some enigmatic flint cores, scrapers and curious flake artifacts which appear to tie the cultures of the period before 1000 B.C. with central Asia, no Archaic remains, as such, have been discovered in the arctic. The Eskimo cultures appear to have come full-blown from Siberia. Pre-Eskimo remains cannot be readily ascribed to specific Asiatic sources, but appear to resemble Lake Baikal remains. The arctic cultures bear marked resemblances to one another for the 3,000 years they have existed. This is not surprising in view of the limited resources and rigid controls established by the environment, where the problems of subsistence and survival have not changed greatly. Generally the Eskimo and pre-Eskimo people subsisted upon large mammals; most were sea mammals. All the mammal hunters possessed permanent wooden houses, the kayak, umiak, snow goggles, wooden and clay utensils, hand sleds, many varied tools of bone, ivory, stone and driftwood, and many ornaments. Rubbed slate knives and points are a characteristic of the later cultures. Asiatic elements include the houses, skin boats, sleds and toboggans, toggle harpoon head, stone blades inserted on sides of wooden tools, spear thrower and bird darts, needle cases and a few other traits.

All the arctic artifacts are rich and varied in art styles. Art style and variations of artifact form permit differentiation among cultures, but the classes of artifacts and their uses are very uniform.

ARCHAEOLOGY, SOCIETIES OF. The first archaeological society met in London around 1585 or 1586. An outgrowth of the antiquarian interest of the 16th century, it was formed by a group interested in collecting and preserving British antiquities. It was soon abolished by James I on political grounds, but was revived in 1707 and formally established as the Society of Antiquaries of London in 1717. In 1751 it received its charter from George II. The activities of this society, whose membership is elective, have included the publication of *Vetusta Monumenta* (1747–1883), *Archaeologia* (1770–), *Proceedings* (1843–1920) and *Antiquaries Journal* (1921–), as well as the excavation and investigation of numerous sites in England.

During the late 18th and early 19th centuries increased interest in local archaeological remains led to the formation of other similar societies such as the Society of Antiquaries of Scotland (1780); the American Antiquarian Society (1812); the Société Royale des Antiquaires de France (1814), successor to l'Académie Celtique (1804); the Royal Society of Antiquaries of Ireland (1890), originally the Kilkenny Archaeological Society (1849) and later the Royal Historical and Archaeological Association (1869); the Royal Society of Nordic Antiquaries in Denmark (1825); the British Archaeological Association (1843) and the Royal Archaeological Institute of Great Britain and Ireland (1843); and even the Archaeological Society of Leningrad (1846). By the mid-19th century numerous county and provincial societies had been formed, particularly in the British Isles, the Scandinavian and Low Countries, France and Switzerland. Many of these engaged in field work. At the same time a strong interest in the prehistoric developed. This resulted in the late 19th and 20th centuries in the foundation of professional societies devoted more specifically to prehistoric and anthropological studies and

also of many state historical societies in the United States.

While this interest in national history and culture was growing, attention also was being directed to the classical antiquities of Greece and Rome. In 1734 the Society of Dilettanti was formed in England. At first it was devoted to discussion by travelers returning from the Mediterranean, but it soon acquired a serious interest in Greek and Roman archaeology. It supported several expeditions to Greece and Asia Minor before falling into obscurity around 1800. It was followed by a number of societies interested in classical and near eastern archaeology.

In 1829 the Istituto di Corrispondenza Archeologica was founded in Rome as an international undertaking under the auspices of Prince Friedrich Wilhelm of Prussia. By 1871 it had become a Prussian institution. In 1874 it changed its name to the Kaiserlich Deutsches Archäologisches Institut and established a branch in Athens. Following reorganization in 1885 it moved its headquarters to Berlin while maintaining the branches in Rome and Athens. Other branches have since been formed in Mainz, Ger.; Istanbul; and Madrid. It has published a number of technical journals, most notably the *Jahrbuch* (1887–) and *Mitteilungen der römischen und athenischen Abteilung*, and has carried out and published reports of extensive excavations in the Mediterranean area. Supported by the German government, it is a purely professional society.

In 1837 Greece formed another professional group, the Greek Archaeological Association. It also has excavated widely and published its reports in *Ephemeris Archaiologike*. In France the Académie des Inscriptions et Belles-Lettres, organized in 1663, although wider in interest, gave its support to the study of classical antiquities as did also the Association pour l'Encouragement des Études Grecques en France which published the *Revue des Études Grecques* (1888–). Archaeology has likewise received aid in Italy from the Accademia Nazionale dei Lincei, originally founded in 1603.

Increasing interest in archaeology was felt too in the United States, where the American Oriental Society was formed in 1842 and the Archaeological Institute of America in 1879 (incorporated in 1906). The latter, concerned primarily with classical archaeology at first, later widened its interests to include many fields of old and new world archaeology. Composed of member societies located in many cities, it is open to anyone interested. It has helped to found and is allied with American archaeological schools in Athens (1882); Rome (1894); Santa Fe, N.M. (1907); Jerusalem (1900); Baghdad (1923); and Egypt (1950); and the American School of Prehistoric Research (1921). It has also sponsored excavations, published a monograph series, the technical *American Journal of Archaeology* (1897–), the more popular *Art and Archaeology* (1916–34) and *Archaeology* (1948–) and a *Bulletin* (1910–) and provides lecturers for its member societies.

The Society for the Promotion of Hellenic Studies (1879) and the Society for the Promotion of Roman Studies (1910) in England are open to all interested and publish journals of a technical nature, but they are wider in scope, including literature and history as well as archaeology. Mention should also be made of the Austrian Archaeological Institute (1898) with a branch in Athens and the Deutsche Orient-Gesellschaft (Berlin, 1898).

ARCHAEOPTERYX is the group name applied to the most ancient known fossil birds whose remains come from the lithographic limestones of the Upper Jurassic beds near Solnhofen, Bavaria.

Remains of birds were first reported from these deposits by E. F. Baron von Schlotheim in 1820, but these initial discoveries were lost so that their identity is not certain. Only four fossil specimens of the primitive birds of the Upper Jurassic are known. One consists of an isolated feather, two skeletons are fairly complete and one is fragmentary.

In 1861 H. von Meyer described an excellently preserved impression of a feather from these beds under the name *Archaeopteryx* ("ancient wing") *lithographica*. The two halves of this imprint were placed in paleontological museums in Munich and Berlin. Later in the same year Ernst Häberlein secured a skeleton lacking most of the skull but with excellent impressions of the feathers of wing and tail at Langenaltheimer Haardt near Pappenheim in the same region. This was purchased by the British Museum of Natural History and described by Sir R. Owen in 1863 as *Archaeopteryx macroura*.

The second skeleton, found in 1877 in similar beds at Blumberg bei Eichstätt, came into the possession of another Ernst Häberlein, a son of the first one, and was secured for the Museum für Naturkunde in Berlin through Werner von Siemens. This example, preserved in two plates of stone, has the skull and is otherwise more complete than the one in London. A third skeleton, with the limbs, vertebrae and other bones, discovered in 1956, but not described in print until 1959, was found 820 ft. from the site of the London specimen.

On preliminary examination the two original skeletons were called the same species, but on study it was found that they differed somewhat, so that in 1897 the Berlin specimen was named *Archaeopteryx siemensi* by W. Dames. Later B. Petronievics separated the Berlin example as a distinct genus, which he called *Archaeornis* so that it became known as *Archaeornis siemensi*.

FIG. 1.—ARCHAEORNIS, ONE OF THE EARLIEST-KNOWN BIRDS

(Top) Drawing of the fossil remains of *Archaeornis*, after the original in the Berlin museum; (bottom) restoration of *Archaeornis* based upon the fossil specimen above

(*See* fig. 1.) However, it must be added that G. De Beer after study of the London specimen considered that the two represent a single species and attributes the differences to age or sex. The third skeleton is said to agree in size and characters with the one in London. The obviously primitive structure, with many reptilian characters, has led to much discussion as to whether they should be classified as birds or as reptiles.

The reptilian affinity is clearly indicated by the form of the skull, especially in the forward portion, where the absence of a bill, the presence of teeth and the relation of the bones to one another are unlike the condition presented by modern birds. Other skeletal elements, particularly the pelvis and the shoulder girdle, also show different degrees of resemblance to reptiles. Further, P. R. Lowe stated that in the London example the impressions of the wing feathers have both inner and outer webs equal in width, with the barbs apparently not firmly joined, instead of one web decidedly narrower and the whole a firm surface, his conclusion being that the animals should be considered more nearly related to dinosaurs.

If feathers are accepted as the main distinguishing character of the class Aves, however, it seems necessary to call both *Archaeopteryx* and *Archaeornis* birds. As such they stand as the most primitive known in this group, to be placed in a distinct subclass, the Archaeornithes (ancestral birds) and in the order Archaeopterygiformes.

Archaeopteryx macroura, in life the size of a small crow, shows as an outstanding peculiarity a long tail of 20 vertebrae (resembling the reptilian type) with feather impressions along the sides and at the end. (*See* fig. 2.) The foot has fairly strong toes, adapted for perching and for walking or running, the tarsal portion being rather short in proportion, with the anterior elements fused with the tibia. The three metatarsals appear to be free, not fused as they are in adult modern birds. (*See* Bird: *Form and Function.*) The other leg bones are slender. Of the anterior limb bones the upper arm or humerus is slightly longer than the forearm. There are well-marked impressions of large wing feathers, the best preserved being about six inches long and one inch wide. There are indications of smaller body feathers.

The hand apparently had the metacarpal elements separated instead of fused into a carpometacarpus as in modern birds. There is indication of three separate fingers which terminate in claws; these are best preserved in the fossil specimen in Berlin. Concerning the bones of the pectoral girdle: the scapula meets the coracoid at a wide angle and fuses with it. The coracoid, a rectangular plate with a foramen and two notches on the inner margin, was given special study by Petronievics, who believed that he could distinguish a line marking off a precoracoid. The free angle of the joined clavicles, or furculum, is present, and near it a small part of the sternum. Its form is uncertain since its presence is known mainly from X-ray photographs.

The bones of the pelvis are separate, and the two pubes meet behind, symphysis apparently having been effected by a rounded mass of cartilage. There is indication of an obturator foramen. The sacrum is composed of six vertebrae. The skull is represented by a partial cast of the brain cavity; a fragment of the premaxilla, including pointed teeth that are elliptical in outline; and other scattered elements.

The later fossil skeleton, representing *Archaeornis siemensi*, has a skull in which the maxilla and premaxilla bear pointed teeth, and the hard bill of modern birds is absent. The skull in fact is distinctly reptilian, differing from that of modern birds and resembling reptiles in having the lower margin of the preorbital fenestra bounded by the maxilla instead of the jugal; in the small size of the brain; in the greater forward extension of the parietal and in other details of relation of the bones to one another.

Petronievics found 9 cervical vertebrae, part of them with ribs attached, 13 dorsal vertebrae and 20 caudal vertebrae, the latter number being the same as that in *Archaeopteryx macroura*. The scapular articulation with the coracoid is free (not fused, as in *Archaeopteryx*). The anterior tarsal elements are not fused with the tibia, and the three metatarsals likewise are free. There are

excellent impressions of the feathers of wing and tail. *Archaeornis* is somewhat smaller, being about nine-tenths the size of *Archaeopteryx*.

While it is customary in restorations to show these birds perching in trees, it seems equally probable that they also ran about actively on the ground. However, they had progressed far in adaptation for aboreal life, as the first toe is turned back to form a foot fitted for grasping rounded branches.

ARCH AND VAULT. The arch is an architectural device primarily used for spanning intervals of space in one major vertical plane by means of inclined or curved masonry, as opposed to horizontal beams (trabeation). Structurally arches perform three functions: to cover, support, and buttress. But they have also been used in purely decorative ways and on occasion have been made to carry elaborate overtones of symbolism. When masonry forms based on the arch are used to cover extended spatial compartments, the result is a vault. (*See* Architecture.)

ARCH

Structure

Arch construction depends essentially on the mechanical properties of the wedge. If a series of wedge-shaped blocks—generally known by the French term *voussoir*—are set flank to flank in the manner shown in fig. 1, the result is an arch. During construction of the arch the voussoirs require support from below until the keystone has been set in place. This support usually takes the form of temporary wooden centring. Similar formwork is needed for all vaults, with the exception of domes, which are in principle self-supporting at every stage of construction by virtue of their concentricity. Theoretically the minimum number of voussoirs required to make an arch is two. In that case they simply lean against one another and the arch is triangular. There is no reason other than convenience why the voussoirs should be identical in shape or their joints radial (*i.e.*, converge on a common centre). If they are, then the arch is semicircular; but many variants are possible.

Within the limits of masonry construction, arches have two advantages over horizontal beams. (1) They can span much

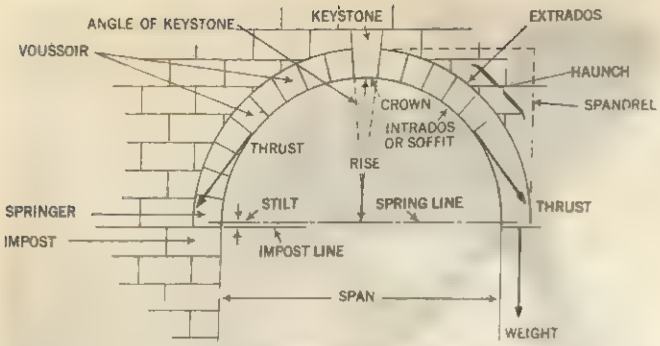

FIG. 1.—ELEMENTS OF THE ARCH

greater distances. The longest unsupported stone architraves in classical Greek architecture are seldom more than 20 ft.; any space much greater than this could be safely spanned only by timber. On the other hand, the Romans projected vaulting spans of up to 150 ft. (2) The arch can also carry a much greater load than a horizontal beam can. This carrying capacity follows from the fact that, subject to certain conditions, pressure downward on the extrados has the effect of forcing the voussoirs together instead of apart. (For terms *see* fig. 1.) One of the conditions is that the load on the crown of the arch should be less than that on the haunches, the crown being the weakest point. The critical factors here are the angle of the keystone and the depth of the bearing surfaces of the voussoirs. In a simple pointed arch, where two arcs of the same radius are struck from different centres, the weak crown of the semicircular arch is so to speak left out—an aspect well conveyed by the French term *arc brisé* (broken arch). In a pointed arch the angle of the keystone is also relatively wider. It follows that a pointed arch should be more efficient than a corresponding semicircular arch. Pointed arches are also more versatile than semicircular arches in that their height is no longer determined by their span. This geometrical factor was important during periods when arches had to be fitted into the proportions of predetermined space frames. In this respect the pointed arch resembles other nonsemicircular arch forms; *e.g.*, the segmental (an arc less than a semicircle), the horseshoe (an arc greater than a semicircle), and the stilted arch (an arch with one or more vertical courses between the springers and the impost blocks). To these may be added the mathematically more complicated arches based on elliptical, parabolic, or catenary curves.

The simplicity and aesthetic perfection of the semicircular arch, however, have secured for it recurrent favour for decorative purposes, and it has always been the form to which symbolic interpretations have most readily accrued. Even when the structural advantages of nonsemicircular arch forms were recognized, predilection for the visual properties of semicircular arches resulted in some curious hybrids; for example, in Apulia, Italy, especially in 12th-century buildings, a semicircular intrados is often found combined with an elliptical extrados, a form created by increasing the lengths of the bearing surfaces between the adjacent voussoirs toward the centre of the arch.

Voussoirs can also be combined to produce a horizontal as opposed to a curved profile. This application of the principle of the arch to the construction of what is in effect an architrave was used occasionally in both classical Roman and Romanesque architecture. When it was done, the voussoirs were often stepped or "joggled" for greater efficiency.

The false arch, as its name implies, is not really an arch at all but a combination of horizontal stones each cantilevered out beyond the one below to form an arch profile. Unlike any of the true arches, this kind is useless for carrying purposes and is therefore generally found only in vaults.

History

Ancient and Classical Times.—The earliest evidence for the use of arches is provided by vaults (*see* below). Large-scale false-arch forms occur extensively in imperial Hittite architecture. The best-preserved examples are the monumental gateways in the walls of the capital, Hattusas (Bogazkoy), built in the middle of the 2nd millennium B.C.; their shape suggests a catenary curve. The technique of the false arch passed from Asia Minor to Mycenaean Greece during the third quarter of the 2nd millennium B.C., and a modified version occurs in the Lion Gate of Mycenae itself.

Where the voussoir was invented is not certain. Bricks arranged like voussoirs and dating from the 9th century B.C. have been found in tombs at Tell Halaf (north Syria). If the reconstructions of the excavators of Tell Halaf are correct, one at least of the arches they once formed was pointed. The bronze bands from a door (now in the British Museum) from the Assyrian palace at Balawat (9th century B.C.) indicate that round arches for city gates were already a familiar feature in the Assyrian world. The reconstruction at Berlin of the Ishtar Gate of Babylon (early 6th century B.C.) gives some idea of what such gates must have looked like.

The Greeks made little use of the arch in their temple architecture, though there is evidence of arched gates in Greek cities, for example, at Elea (Velia) on the coast of Lucania, Italy (5th century B.C.). But the first exponents of arch construction in Europe seem to have been the Etruscans. It is conceivable that they brought this technique with them from their putative homelands in Asia Minor when they emigrated to central Italy, and the Greeks may have learned about arches from them. The question whether the Romans learned from the Etruscans or from the Greeks is still under discussion. Either way, however, it was in Roman Italy during the Late Republican period that the arch was first exploited on a grand scale both as a structural device and a symbolic form; *e.g.*, the aqueduct and the triumphal arch (*qq.v.*).

Development of the Pointed Arch and Its Religious Connotation.—During the first three centuries of the Roman Empire,

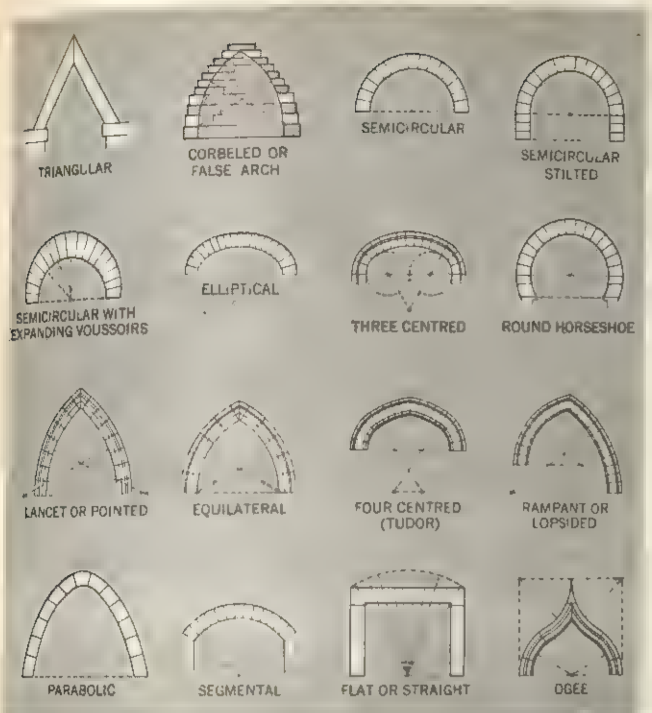

FIG. 2.—COMPARATIVE ARCHES

construction of arches went hand in hand with the construction of large-scale vaults (*see* below), and it was perhaps during this period that the advantages of nonsemicircular arch forms were first explored. Although there is some evidence for these forms among the surviving monuments of Rome, the most spectacular instances are to be found outside the empire in the palaces of the Sassanid Persians at Ctesiphon, near Baghdad, and Bishapur and at Constantinople in the great arches supporting the domes of Hagia Sofia and Hagia Irene (6th century A.D.). The spread of these variants is not easy to trace, but it seems that the pointed arch was already known in the 7th century when the Arabs occupied Syria and Persia. Whether or not it had a continuous history extending back to Tell Halaf is uncertain. As a purely decorative form on a miniature scale, the pointed arch appears in sculpture of the Gandhara period of ancient India (in what is now northwestern Pakistan), probably under Persian influence. The Arabs were certainly responsible for popularizing the pointed arch, and it was in mosques that this form first acquired a religious connotation. Christian architects in Western Europe who adopted the pointed arch in the late 11th century may have been trying to emulate their Muslim contemporaries. But they may equally have been trying to revive constructional techniques of the late Roman Empire, perhaps stimulated by renewed contacts with remote parts of the Eastern Christian world such as Armenia, where the pointed arch had long been in favour.

During the four and a half centuries from 1100 to 1550 arches were most widely used in European architecture, especially in churches and monastic buildings, whose ribbed vaults and flying buttresses reveal the arch as the first principle of Gothic structural engineering. Churches of that period became veritable systems of arches in which walls, windows, and roofs served only as screens against the weather. The ubiquitous use of the arch during the Gothic period can be plausibly explained in terms of structural advantages. But it is only necessary to compare churches with secular and military buildings of the same period to recognize the extent to which arches were used to make churches "different"—that is, the decorative and symbolic aspects of the arch were probably every bit as important as the structural. There is no unambiguous written testimony as to the nature of this symbolism, however, and the hypothesis must be left vague.

Gothic Principles of Construction.—A great variety of arch forms was used during the Gothic period. The earliest pointed arches seem to have been constructed according to certain rules governing the relation between the radius of the arcs and the span of the arch. The mid-13th-century additions to the notebook of Villard de Honnecourt (*q.v.*) contain cryptic allusions to *tiers-point* and *quint-point* arches, in connection with diagrams purporting to show how to make keystones. The angle of the keystone is determined by the position of the centres of the arcs in relation to the total span. *Tiers-point* probably meant that the radii were two-thirds or three-fourths of the span, *quint-point* that they were five-sixths or five-eighths. Another favoured formula was the equilateral arch in which the radii and the span were identical (also sometimes called *tiers-point*). In England, however, as early as the rebuilding of the choir of Canterbury Cathedral (after 1174) architects were prepared to put arcs of different size and radius together to produce lopsided arches; to depress arches by making the profile of the springers oblique; and even to introduce angles into the arcs. Phenomena of this kind betray a preoccupation with the visual as opposed to the mathematical conception of arch construction, and it is not surprising that the English took the lead during the following century in developing the possibilities of the ogee arch in which reversed curves appear. From this it was a short step to the nodding ogee, in which the reversed curve changes direction in two planes at once, and the arch inclines forward in a complex curve. Later still other forms of multicentred arches were popular in England. It was, however, reserved for the Germans and Bohemians in the 15th century to produce the most spectacular of all variations of the arch form: monumental nodding ogees, used for porches and vaults. These culminate in the work of Benedikt Reid in the Vladislav Hall (1493–1502) at Prague (*see* also below, *Vault*).

Renaissance to Modern Times.—With the Renaissance there was a strong reaction against the pointed arch in favour of the semicircular, the Roman arch form par excellence. Round arches also conformed well with Renaissance theories about mathematical perfection in architecture. On the other hand Baroque architects, who made great play with ovals in their designs, were often prepared to use elliptical or depressed arches.

Builders of churches continued to make use of arch and vault, but in secular buildings, which tended more and more to become

suites of rooms on many floors, flat ceilings and rectangular doors and windows became more or less obligatory. It was not until the 19th century, with the construction of great public utilities such as bridges, viaducts, and halls to serve as railway stations or museums (not to mention neomedieval churches), that the arch became once more an important element of architectural construction. After Galileo, the mechanical properties of catenary arches could be explained theoretically. Moreover, new materials, in particular iron and steel, allowed structural engineers to construct arches of unprecedented magnitude; *e.g.*, the Bayonne (N.J.) Bridge across the Kill van Kull, which spans 1,652 ft. (504 m.; *see* BRIDGES).

VAULT

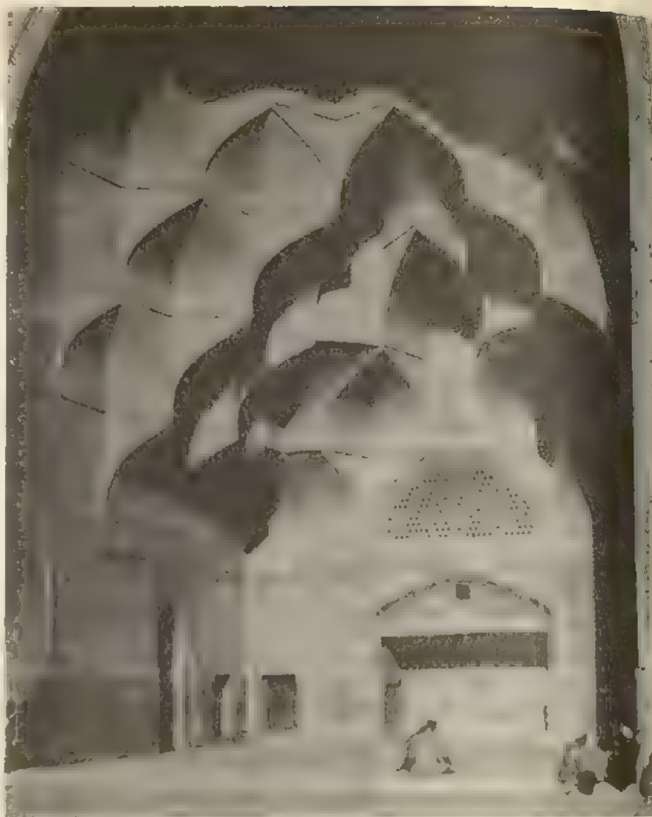
STRUCTURE AND BASIC TYPES

The simplest way to turn an arch into a vault is to broaden the soffit, creating what is called a barrel, tunnel, or wagon vault. If two barrel vaults are crossed at right angles over the same space, the result is a groined vault. If an arch is rotated through 180° the result is a dome (*q.v.*). These are the three basic forms of vault. Each is suited to a particular kind of plan: the barrel vault to a rectangle, the groined vault to a square, and the dome to a circle. Other types of vault have arisen from the desire to adapt one of the basic vault forms to a space to which it was not naturally suited. For instance, it is possible to combine four triangular pieces of barrel vault over a rectangular or square bay, to produce something approximating to a dome (the so-called cloister vault). Other variations arise from the use of nonsemicircular rather than semicircular arches; and a further alternative is represented by vaults constructed on the principle of the false arch.

HISTORY

Ancient and Classical Times.—The earliest vaults known—tombs at Ur in Mesopotamia and passageways inside the Egyptian pyramids (*c.* 2700 B.C.)—are vaulted on the principle of the false (or corbeled) arch; so also were the beehive tombs of Mycenaean Greece, the best-known of which still intact is the so-called Treasury of Atreus at Mycenae (*c.* 1300 B.C.). Later and less impressive examples occur in Etruscan cemeteries, as at Cerveteri and Vetulonia. The same principle is represented in primitive Irish architecture of the early Christian period; *e.g.* the Oratory of Gallarus at Dingle, County Kerry. The technique has persisted in Italy as a feature of the domestic architecture of central Apulia (as at Alberobello).

Apart from early miniature vaults over tombs, vaulting based



COURTAULD INSTITUTE OF ART

STALACTITE VAULT

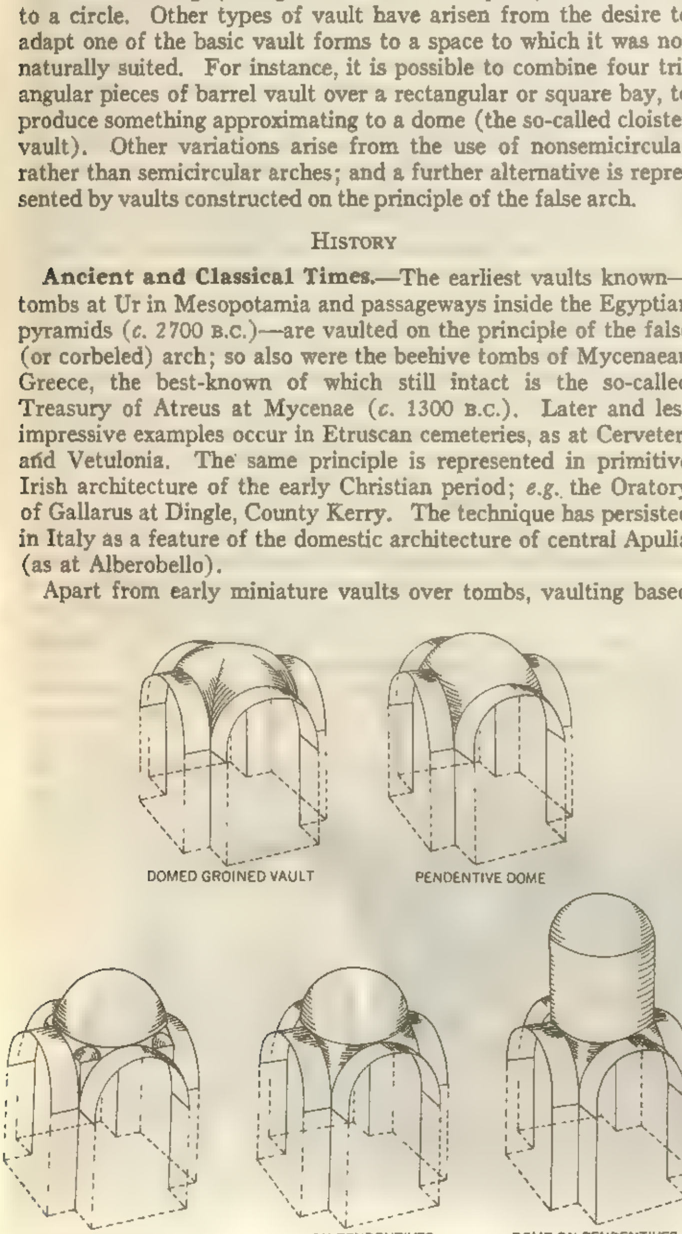
on voussoir arches may have been a feature of Hellenistic palace architecture at Antioch and Alexandria. But the first real evidence is provided by Roman Republican monuments. Roman vaults were occasionally made of cut stone, but they are closely associated with the use of concrete. By the end of the Republican period most of the technical problems posed by the handling of concrete had been solved; yet the scale on which this material was used remained small. Surviving examples include the barrel-vaulted city bath at Pompeii and the underground basilica near the Porta Maggiore in Rome.

It was left to the great imperial patrons (from Nero onward) to exploit the possibilities of vaults over large spaces. From the Golden House of Nero (A.D. 64) to Hadrian's Villa at Tivoli (*c.* A.D. 130) a series of vaulted buildings was constructed in or near Rome which provided models to which reference was continuously made in subsequent centuries. These include the Aula Regia of Domitian's Palace on the Palatine Hill, built by Rabirius (*c.* A.D. 90), which was probably barrel-vaulted; the halls of Trajan's Market and Trajan's Baths, which were groin-vaulted; and the Pantheon, which was domed. A Greek mathematician, Hero of Alexandria, is known to have written a manual, the *Camarica,* on vaulting (now lost). Hero's dates are not certain, but if, as has been inferred from other evidence he lived during Nero's reign, his book may have provided the necessary basic instruction for Roman architects.

Byzantine Building: Hagia Sophia.—References to "the mechanicians of Hero's school" occur now and then in writings of the next five centuries. Isidore, the architect who was commissioned to replace the dome of Hagia Sophia at Constantinople after the original collapsed in 558, wrote a commentary on Hero's treatise, a fact that testifies to the relevance of this work. Both domes of Hagia Sophia were placed over a cubic space as opposed to a cylindrical, which sets the problem of how to effect a transition at the top of the space from a square to a circle. Basically, three solutions are possible. The simplest, usable for comparatively small spans, is to place horizontal beams across the



AFTER K. J. CONANT, "A BRIEF COMMENTARY ON EARLY MEDIAEVAL CHURCH ARCHITECTURE"

FIG. 3.—THE DOMED CROSS WITH VARIOUS VAULTING COMBINATIONS

corners, each projecting farther than the one below, until an octagon has been formed; and then to place the dome on the octagon. The second is to use arches (called squinches; *see* SQUINCH) instead of horizontal beams, a method that also results in an octagon but one of greater structural efficiency that can be safely enlarged. The third solution, and the one selected by the architects for both domes of Hagia Sophia, was to construct a dome whose diameter was the diagonal of the square. The result was four spherical triangles, called pendentives (*see* PENDENTIVE), emerging from the angles of the cube. If the pendentives are sprung at the right level, they combine to form a circular base.

Domes on pendentives seem to have been used on a small scale in a number of 5th-century buildings, but their first large-scale use was at Hagia Sophia. In the first design for that church the curve of the upper part of the dome may have been continuous with that of the pendentives. In its successor, however, the dome proper is struck to a smaller radius, and there is therefore a distinct break between the dome and the pendentives. The situation in Hagia Sophia is further complicated by the fact that the arches on which the dome is carried, and which therefore define the pendentives, are not simple semicircles; the pendentives themselves, therefore, are mathematically complex. It is not certain that these deviations from strict symmetry were made in the interests of greater structural efficiency; they more likely embody attempts to achieve preselected ratios between the various levels of the design.

The dome on pendentives, once established, proved so well suited to the aesthetics and iconography of Byzantine churches that it remained a central feature of nearly all subsequent Eastern Christian architecture.

Muslim Vaults.—The dome was quickly adopted by Muslim architects, who took it to India and Central Asia. They also developed forms of vault peculiar to themselves; *i.e.*, stalactite vaults, which are actually complicated squinches, for porches and *mihrabs* (the *mihrab* being a niche in the wall of the mosque indicating the direction of prayer); and intersecting parallel ribs, usually eight in all, for supporting domes. Isolated examples of both occur in medieval European buildings, among them stalactite vaults in the Capella Palatina at Palermo, Sicily, and intersecting parallel ribs in Spain.

Medieval Vaults.—In Western Europe large-scale vaulting was associated throughout the Middle Ages with church buildings. It began with barrel vaulting over the chancel, partly to protect the altar and partly to give the chancel a more imposing setting; an early example may be seen at Agliate near Milan. Subsequently in the 11th century the barrels were extended to cover the whole church. This form, which was much favoured in southern France, Italy, and northern Spain, required both continuous support and continuous buttressing, which made it difficult to combine with large clerestory windows. In the church at Tournus, France (late 11th century), instead of one continuous barrel, a series of short transverse barrels is carried on arches across the nave. A more satisfactory solution to this problem, however, was provided by the groined vault, which made an early appearance in hall crypts and porches but was not widely used for major spans until the end of the 11th century. Northern Italy may have been its place of origin, but it was soon established in Germany and Normandy.

RIBBED VAULTING

Intersecting segmental arches forming pointed ribbed vaults in Durham Cathedral, England; Romanesque (Norman), about 1100

Groined Vaults.—A true groined vault is the result of intersecting two barrel vaults over a square bay. If the barrels are identical, the lines of intersection (the groins) form elliptical curves. Mathematically these are complicated, a by-product of the simple curves of the surface of the vault. If the bay is rectangular instead of square, one of the barrels has to be stilted, and in consequence the groins undulate. But even in such early Roman buildings as the Baths of Diocletian (late 2nd century A.D.) may be seen groined vaults, over rectangular compartments, in which the undulations have been straightened. In spite of the shape of the compartment, the groins are in effect elliptical arches. It follows that the several surfaces of the vault have ceased to have a strict mathematical connection with one another.

In the 11th and 12th centuries medieval architects slowly realized the possibilities of these simplifications. The earliest surviving example of straight groins over rectangular bays is to be seen in the nave of the abbey church at Vézelay, France (12th century), but by *c.* 1100 at Norwich, Eng., straight groins had been applied to the task of vaulting a turning ambulatory—mathematically perhaps the most difficult of all vaulting problems to solve. At Norwich the groins are no longer regarded as complete arches but are four arcs converging on a predetermined centre where they achieve equilibrium. This technique anticipates by some 40 years the more or less identical solution worked out in terms of ribbed vaults for the ambulatories of Saint-Denis, near Paris.

Ribbed Vaults.—In vaults of this kind the groins take logical priority over surfaces: they are the starting point rather than a by-product. The first step was to emphasize the groins visually by applying solid moldings to them. In the Baths of Diocletian, the groins were strengthened by embedding arches of flat tiles in the concrete. Originally these were not meant to be seen, but in decay the tiles must have begun to project and they may have provided a structural prototype for the most widespread of medieval vaulting forms, the ribbed vault. The rib, like the barrel and groin, may have originated in northern Italy at the end of the 11th century. But the great development of ribbed vaulting was all in the north, where the earliest, in the cathedral at Durham, Eng. (*c.* 1100), was virtually contemporary with that seen in north Italy. The earliest surviving vaults at Durham, in the choir aisles, are really no more than intersecting segmental arches, not clearly related to the wall and pier articulation and therefore perhaps conceived as a strengthening framework under the vault rather than as an integral part of the design. It is the sense of

being totally integrated into an all-embracing system of arches that distinguishes subsequent Gothic ribbed vaults.

No doubt symbolism played a part in making ribbed vaults popular, but the nature of this symbolism is no easier to establish for vaults than it is for arches. Intersecting diagonal ribs (*croisée d'ogives*) certainly resembled the ciborium over the altar of Old St. Peter's, Rome, and a ribbed-vaulted bay could thus be regarded as a kind of ciborium writ large. Symbolic interpretations presumably followed rather than preceded structural innovations, although in the series of French Gothic buildings that link Abbot Suger's Saint-Denis (*c.* 1140) with Louis IX's Sainte-Chapelle (1240) structure and meaning seem constantly to have interacted with one another.

The use of pointed arches in the construction of Gothic ribbed vaults appears to have evolved very slowly. Contrary to a widely held belief, the fact that pointed arches could be adjusted so that the crowns of arches over different spans could reach the same height played little or no part in the process. On the contrary, it is already evident in the vaults over the nave of Durham Cathedral (1128–33) that the diagonal ribs were meant to be semicircular, and the transverse ribs, which cover a shorter span, are pointed precisely because they are struck to the same radius. The same idea may be observed in France in the sexpartite vaults of the cathedrals of Sens (*c.* 1140), Laon (*c.* 1170), and Bourges (*c.* 1200). A good deal of simple mathematical ingenuity was devoted to the design of these vaults. For instance, at Laon the dimensions of the double bays allowed the spans of the ribs to be calculated in terms of a Pythagorean triangle (actually 6: 8: 10). Thus the diagonal ribs have a radius of 5 and a span of 10, while the transverse arches have a radius of 5 and a span of 8. The transverse arches thus were *quint-point*. Not until the very end of the 12th century, in the cathedral of Chartres, was the decisive step taken of making all the vaulting arches pointed.

Elaboration of the Ribbed Vault: England.—The later history of medieval vaulting is to be traced largely outside France. A fundamentally different approach to the design of ribbed vaults is to be seen at Lincoln Cathedral in England, where, over St. Hugh's choir (*c.* 1200), a ridge rib is combined with two keystones and the first asymmetrical ribbed pattern. In the course of the 13th century in England the tendency was to increase the number of keystones still further and to crowd as many ribs as possible into the space available (tiercerons), even if this meant having ribs which did not reach the centre of the vault. These designs are based on the notion of ribs diverging from a common springer as opposed to the French idea of making them converge on a common apex. The logical outcome of the English practice was the cone of ribs in a centrally planned building such as a chapter house. Here again the crucial prototype occurs at Lincoln, where the ten-sided chapter house with 20 ribs was built *c.* 1230. Others followed at Lichfield, Salisbury, Westminster, Elgin, and Wells. The one at Wells (*c.* 1300) with 32 ribs is the most spectacular.

During the last years of the 13th century two other important features, both used decoratively, appeared in English vault design: one was the flying or skeleton rib (a rib with no filling), the other was the lierne (a rib which starts on one rib and ends on another). Liernes were at first concentrated in the higher central parts of vaults, where their function was roughly analogous to that of tracery (*q.v.*) in windows. The design of both vaults and windows required more careful planning than other types of masonry work did, and surviving Gothic architectural drawings are largely concerned with the geometry of vault and window patterns. In England the formal affinity between tracery and vaults reached the stage of virtual identity in the fan vault. The earliest fan vaults still surviving are in Gloucester cloister, dating from 1351 onward. Here they are no longer ribs in the ordinary sense of the word at all, but developing cells of tracery cut into the surface of the vault, the patterns being slightly modified projections of 13th-century rose window designs.

Fan vaults were suited to the smaller spans of aisles and cloisters, but it was not until the end of the 15th century that they were applied to the major spans of high vaults. The earliest of these apparently were at Sherborne Abbey, and the success of this experiment led to their use in two major works of the early 16th century, King's College Chapel at Cambridge and Henry VII's Chapel at Westminster Abbey. In both these buildings fan vaults are used in conjunction with powerful transverse ribs. At Westminster fans are ingeniously "threaded" on the transverse ribs so that the ribs disappear behind the fans in the greater part of the span. The fans terminate in pendants which must have been derived from the corresponding features of timber hammerbeam roofs (*see* HAMMERBEAM ROOF). Fan vaulting seems to have been an English specialty, and there is nothing comparable to it elsewhere in Europe, although the use of pendants in conjunction with elaborate ribbed patterns was widespread. Examples are found from Portugal to Austria.

Elaboration of the Ribbed Vault: Germany and Central Europe.—It is likely that English experiments with the visual aspects of vault design lie behind the development of Late Gothic vaulting in Germany, Austria, and Bohemia. The earliest of the elaborate German patterned vaults occur *c.* 1300 in the Baltic coastlands dominated by the Teutonic Knights. By the middle of the 14th century these ideas had percolated south through Silesia to Bohemia where they received fresh emphasis from the work of Peter Parler at the cathedral of Prague. Parler's "net vault," the essential principle of which was parallel as opposed to diverging ribs, was to prove particularly popular with German architects throughout the 15th century.

The last phase of German medieval vaulting was dominated by three major ideas. (1) The first of these was the double reversed curve, which the Germans—in contrast to the English, who were content to use this in the miniature form of the "nodding" ogee—used on a colossal scale to produce the most extravagant of all medieval patterned vaults. The architect whose name is most closely associated with this kind of vaulting is Benedikt Reid, whose masterpiece was undoubtedly the Vladislav Hall (*c.* 1500) in the Royal Palace at Prague. The ribs writhe and twist themselves into monster flower shapes that spread over some 60 ft. (2) A second characteristic of Late German Gothic was the construction of a pattern of flying ribs under the main one which carried the filling. Some of these became so complicated as to resemble expressionistic works of sculpture rather than architectural forms; in the cathedral at Ingolstadt we are obviously invited to think of the Crown of Thorns. (3) Some architects, working for the most part in Austria and Bohemia, developed the net vault into a system of cells by raising hollow pyramids on the framework of ribs. The visual effect of these is often strikingly modern, and indeed similar vaults have found favour with mid-20th-century architects such as Pier Luigi Nervi.

Postmedieval Vaults.—Insofar as Renaissance architecture revived antique forms, it tended to repudiate the extravagances of Late Gothic ribbed vaults (which in any case had never appealed to Italian taste) and reverted to straightforward barrel and groined vaults, with the dome assuming particular importance. The first of the great Renaissance domes is generally reckoned to be that of Florence Cathedral by Brunelleschi, though the problem of how to vault the dome which Brunelleschi solved (1420–34) had been bequeathed to posterity by the 14th-century architect of the cathedral, Francesco Talenti. The dome's span of about 140 ft. (43 m.) invites comparison with the dome of the Pantheon, and it is almost twice that of the next largest Gothic vault, that over the nave of the cathedral at Gerona, Spain. Michelangelo's dome for St. Peter's at Rome (1547–90) is almost as big as that of Florence Cathedral. For the most part, however, Renaissance vaults were less ambitious and concentrated more on exploiting the perfection of simple geometrical shapes. Baroque architecture, with its interest in compound and reversed curves, provided opportunities for mathematically complicated vaults, but these seldom involved a revival of medieval forms. A striking exception occurs in the work of Guarini (1624–83), who for the domes and lanterns of his two churches in Turin was clearly inspired by the crisscross rib patterns of Muslim and medieval Spain.

Contemporary Vaults.—The third great period in the history of vault construction (that is, after classical Rome and medieval Europe) is undoubtedly the present. Since the middle of the 19th century there has been a demand in industrial countries for covered halls of unprecedented size. Construction of these has led to the exploitation of new materials and new methods, and not least to a new understanding of the mechanical theory of vaulting. Such buildings are characterized by structural efficiency, and for reasons of economy the bare elements of the structure have not been disguised with superficial decoration. They have therefore little in common with traditional architecture. On occasion, however, when trouble has been taken with the design, they have considerable aesthetic appeal and have been hailed as initiating an architectural revolution.

The new materials fall into two categories. On the one hand,

steel and reinforced concrete, which combine great strength under pressure with relative ease of handling, have more or less replaced stone and brick for the construction of very large carrying arches. On the other hand, glass, sheet metal, and thin concrete slabs have made possible very much lighter infilling than was possible with ordinary masonry. These advantages have been enhanced by the development of prefabrication of components in factories. This has now extended to the prestressing of parts, so that, when the building is assembled, warping under pressure or distortion by settlement, which bedeviled medieval if not Roman vault construction, have been virtually eliminated. The importance of prestressing can hardly be overemphasized, for in the very large vaults that were being built by the second half of the 20th century the traditional margins of tolerance would be prohibitive. Much more exact knowledge of the mechanical conditions affecting the behaviour of buildings makes it possible to calculate the minimum effective thickness of a vault, as well as its weight, the stresses to which it will be subjected, and the precise direction of thrusts, together with the necessary allowances for wind and weather. Occasionally calculations can go awry, as in the case of the Tacoma Narrows Bridge (Wash.), which collapsed in 1940. But by and large the total performance of a modern vault can be predicted with great accuracy, and it is in this that modern methods differ most fundamentally from those of the Middle Ages and antiquity, when everything was determined by traditional rules of thumb. This is one reason why 20th-century experiments in vaulting have followed one another with almost hectic assurance.

The characteristic outcome of the new technical knowledge has been the shell vault. Usually made of prestressed, reinforced concrete, shells can be made as thin as 1:500 of their span; further reinforced by ribs, they can be even thinner. They began with comparatively simple forms—for example, Eugene Freyssinet's aircraft hangar at Orly, near Paris (1927), which was a parabolic cylinder; and the Zeiss-Dywidag Planetarium dome at Jena, Ger. (1925). Since then an impressive series of hangars and market and exhibition halls has been built, in both America and Europe; among these Amman and Whitney's Trans World Airlines hangars at Midway Airport, Chicago, achieve a span of 270 ft. (82.3 m.), and Nervi's dome for the Sports Palace at Rome (1960) covers 328 ft. (100 m.).

The latest history of shell vaulting has been concerned with more complicated forms of solid geometry. An alternative to the continuous paraboloid cylinder is a succession of conoid sections joined together by windows. These may be either straight-sided or curved, and the curves may be either simple or conic, concave or convex, parabolic or hyperbolic. Perhaps the most sophisticated of all these compound forms is the hyperbolic paraboloid. The purpose of all these double-curved vaults is to play off one set of stresses against another. This can be done in another way by undulating the vault (making it like corrugated paper or metal) to increase its rigidity without increasing its thickness. Again, the undulations may be arranged in a straight sequence or in a circle or indeed in any number of irregular ways. While considerations of function and economy play a determining part in the design of such vaults, their geometrical versatility lends itself to architectural composition. Joern Utzon's 1957 design for the opera house at Sydney, Austr., and the numerous grouped vaults that appear in the work of the Mexican engineer Félix Candela, certainly aspire to produce aesthetic effects as well as solutions to technical problems.

The more successful of these designs are often oddly reminiscent of vaults from the past. The Spanish exponent of shell vaulting, Eduardo Torroja, observed that an intuitive grasp of the principles of shell construction can be detected in certain very light Byzantine vaults. The modern geodesic method of dispersing stresses evenly through vaulted surfaces is distantly anticipated in the net vaults of 14th- and 15th-century Germany. Austrian and Bohemian Gothic cell vaults call to mind Nervi's shallow span for the Exhibition Hall (1948–50) at Turin. And the groups of ribs cantilevered out of supporting piers like the arms of an umbrella, used by Nervi and Candela in conjunction with their great spans, were foreshadowed by the cones of ribs of English cathedral chapter houses and German hall churches. There is, of course, no question of direct influence or imitation. It is merely that vaults, more than most of the technical features of architecture, can be designed only in a limited number of forms, which accordingly tend to repeat themselves.

ARCHANGEL (Arkhangelsk), an *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., covers 226,795 sq.mi., lying along the northern coast of European Russia from the Gulf of Onega (Onezhskaya Guba) to the eastern side of the Yugorski peninsula. The narrow eastern "panhandle" is occupied by the Nenets National *okrug* (64,749 sq.mi.). Administratively the *oblast* also includes the Solovets Islands in the White sea and the arctic islands of Kolguyev, Novaya Zemlya, Franz Josef Land (*qq.v.*), Vaigach and Matveyev. These islands constitute about one-fifth of the *oblast's* total area. Most of the mainland area displays low relief of morainic hills and mounds with broad valleys of rivers flowing northwest and north to the sea—the Onega, Northern Dvina, Mezen and Pechora. North of approximately 67° N. the area is bleak, open tundra with vegetation of mosses, lichens and dwarf shrubs. Southward tundra gives way to thin, stunted forest and then to dense taiga, coniferous forest of spruce, pine and fir with birch, covering almost the entire area. The climate is severe, with long cold winters and cool summers. Average temperatures for the city of Archangel are 8° F. in January and 59° F. in July. Rainfall averages about 16 in. annually.

The area was opened up as early as the 10th century by fur trappers and traders from Novgorod. Its subsequent importance to the Muscovite state lay in the port of Archangel, through which passed trade with England and, later, Holland. Overhunting gradually reduced the value of the fur trade but in the 19th century timber began to be exported in large quantities.

The *oblast*, which was formed in 1937, is thinly populated, with less than three persons per square mile (counting rural population alone) living mostly along the rivers. The population in 1959 was 1,275,839, of which 674,939 was urban. The main town is the administrative centre of Archangel. The Nenets National *okrug*, with its centre at Naryan-Mar, has about 45,534 persons. The Nentsy are a Finno-Ugrian group, known earlier as Samoyeds (*q.v.*).

The economy of the *oblast* is almost wholly based on forestry. Logs are rafted down the rivers to sawmilling centres at Archangel, Onega, Mezen and Naryan-Mar, or transported by light railway to sawmills along the Archangel-Vologda railway. Other main timber working centres, aside from Archangel, are Kotlas and Konosha. Agriculture is carried on in small clearings near the railways or rivers, and reindeer herding is important in the economy of the Nentsy. Fishing is significant along the coasts and rivers.

(R. A. F.)

ARCHANGEL (Arkhangelsk), a town and the centre of Archangel *oblast* of the Russian Soviet Federated Socialist Republic, U.S.S.R., is situated on the right bank of the Northern Dvina, 31 mi. from the sea, at the point where the river divides into several distributaries. Pop. (1959) 256,309. The town was founded as a fortified monastery, Archangel Michael, in 1583 and took over the functions of the older Kholmogory, farther upstream. Until the founding of St. Petersburg in 1703, Archangel was the largest port of the Russian north. It is now one of the supply ports for the North sea route. The port was of great importance during World War II for Allied convoys to the U.S.S.R. With Solombala and Ekonomiya, it extends for 10 mi. along the right bank of the river. The navigation season is lengthened by use of icebreakers. Its economy is almost wholly linked with timber (about 10,000,000 to 13,000,000 cu.yd. annually), which is either rafted down the Dvina or carried on the railway that runs south from Archangel to Vologda and central Russia. There is large-scale sawmilling, paper and pulp making, wood chemical extraction and manufacture of prefabricated houses. The main power station operates on timber waste. Timber forms the major export of the port, which is also the base of the Dvina river fleet and a fishing fleet. Shipbuilding and repair are important. There is a railway from Murmansk, skirting the southern shore of the White sea, which joins the Archangel-Vologda line at Obozërski. The station at Archangel is on the opposite side of the river from the town; there is no bridge. Another line connects the town with the outport of Severodvinsk on the Dvina gulf.

There are institutes of epidemiology, microbiology and hygiene, timber industry and also a teachers' college. (R. A. F.)

ARCHBISHOP, in the Christian church, the title of a bishop who, besides wielding ordinary episcopal authority in his own diocese, usually has jurisdiction (but no superiority of order) over the other bishops of a province. The functions of the archbishop developed out of those of the metropolitan (*q.v.*), though the title of archbishop, when it first appeared, implied no metropolitan jurisdiction. The title seems to have been introduced in the East, in the 4th century, as an honorary title of certain bishops. In the Western church the title was hardly known before the 7th century, and did not become common until the Carolingian emperors revived the right of the metropolitans to summon provincial synods. The metropolitans then commonly assumed the title of archbishop to mark their preeminence over the other bishops; at the same time the obligation imposed upon them, mainly at the insistence of St. Boniface, to receive the pallium from Rome, marked the defeat of their claim to exercise metropolitan jurisdiction independently of the pope. Its first recorded use is by Athanasius, bishop of Alexandria, who applied it to his predecessor Alexander as a mark of respect.

The title "archbishop" is still used in the Roman Catholic Church as an honorary title for certain simple bishops who are not metropolitans. After the Council of Trent the powers of the archbishop were considerably less extensive than they had been in the Middle Ages. The disciplinary powers once exercised by the archbishop can scarcely be said to survive. The right to hold visitation of a suffragan's diocese or to issue censures against him was made by the Council of Trent dependent upon the consent of the provincial synod after cause shown, and the only two powers left to the archbishop in this respect are to watch over the diocesan seminaries and to compel the residence of the bishop in his diocese. The confirmation and consecration of bishops is reserved to the Holy See. In the Orthodox and other churches of the East the title of archbishop is of far more common occurrence than in the West, and is less consistently associated with metropolitan functions. In the Orthodox Church there are autocephalous archbishops ranking between bishops and metropolitans.

In the Protestant churches of continental Europe the title of archbishop has fallen into almost complete disuse, though it was retained by the Lutheran bishop of Uppsala, who is metropolitan of Sweden, and by the Lutheran bishop of Turku in Finland.

The ecclesiastical government of the Anglican Church is divided between two archbishops: the archbishop of Canterbury, who is the "primate of all England" and the metropolitan of the province of Canterbury, and the archbishop of York, who is "primate of England" and metropolitan of York. The jurisdiction of the archbishop of Canterbury as archbishop of all England extends in certain matters into the province of York.

See also Episcopacy; Ministry, Christian.

ARCHCHANCELLOR: *see* Chancellor.

ARCHDEACON, originally the chief deacon at the bishop's church; during the middle ages, in the west, a chief official of the diocese, second in importance only to the bishop.

Though the name archdeacon does not appear either in east or west until the 4th century, earlier practice knew of a leader among the college of deacons attached to the bishop's service; *e.g.*, the martyr-deacon Lawrence (d. 258). The archdeacon was appointed by the bishop, and, as the name implies, his duties were, besides preaching, to supervise the deacons and their work (*i.e.*, the care of the sick and the arrangement of the externals of divine worship); one of the chief duties of the archdeacon was to supervise the distribution of alms. Thus, with his close relation to the bishop and his employment in matters of episcopal administration, and with the rapid expansion of the church and its revenues in the 4th century, his role grew correspondingly in importance. He became the first assistant to the bishop in the administrative and disciplinary work of the diocese, and represented him at councils. Upon a bishop's death the archdeacon governed the diocese until the election of a successor. In the 5th century the archdeacon was entrusted with the education of the younger clergy; this meant, in practice, decisive control over the admission of candidates to orders. During the 8th and 9th centuries the office tended to become more and more exclusively purely administrative, the archdeacon

relieving the bishop of the minutiae of government and keeping him informed in detail of the condition of his diocese. The archdeacon had thus become, on the one hand, the eyes of the bishop, but on the other hand, armed as he was with the powers of imposing penance and, in cases of extreme disobedience, of excommunication, he assumed his share in the jurisdiction of the bishop. First in France and then also elsewhere, he became officially the "vicar of the bishop in all things," including the right of visitation even of priests.

Beginning with the 10th century, the archdeacon (now generally an ordained priest) achieved a defined territorial jurisdiction, and soon dioceses were divided into several archdeaconries. The office was no longer subject to the bishop, but was conferred irrevocably by the cathedral chapter. This meant, in fact, that archdeacons became rivals of the bishop, functioning to an ever greater degree independently of him and seeking to lessen his spiritual and temporal authority in their respective archdeaconries. Details varied according to country, and the general law of the church did not sanction many of the practices; but an archdeacon of the 13th century exercised in his territory all the traditional rights of a bishop. The only thing lacking to him was the ordination to the episcopate and the power of ordaining.

From the 13th century onward a reaction set in. The power of the archdeacons rested upon custom and prescription, not upon the canon law; and though the bishops could not break the power of archdeacons, they could circumvent their influence by appointing new officials: auxiliary bishops, diocesan court functionaries, vicars forane for the country districts and, most important, the vicar general. Since the clergy could now appeal to these new bearers of authority, the power of the archdeacons rapidly declined during the 14th and 15th centuries. The Council of Trent (1564) completed the process when it withdrew matrimonial and criminal causes from the competence of the archdeacons, forbade them to pronounce excommunications, and allowed them only to hold visitations in connection with those of the bishop and with his consent. In the Roman Catholic Church at present the office of archdeacon is nothing more than an honorary title, and is not even mentioned in the Code of Canon Law.

In the Byzantine Church, the role of archdeacon, similar in its origins to that of its early counterpart in the west, was gradually absorbed after the 7th century by the chartophylax (literally, keeper of the archives), whose office in the course of time resembled somewhat that of the medieval archdeacon. It is now largely honorary. Only in the Anglican Church has the title of archdeacon retained more than nominal significance. Administrative authority is delegated to him by the bishop over the whole or a part of the diocese. In England, he must be an ordained priest. His duties, according to the Anglican ordinal, include the examining and presenting of candidates for holy orders. Other duties vary widely; in general, they concern some degree of supervision over clerical discipline and over ecclesiastical property.

ARCHDUKE (Lat. *archidux*, Ger. *Erzherzog*), a title proper, in modern times, to members of the house of Habsburg (*q.v.*). The title of archduke palatine (*Pfalz-Erzherzog*) was first assumed by Rudolf IV, duke of Austria (d. 1365), on the strength of a forged privilege, in the hope of gaining for the dukes of Austria equal status with the electors (*q.v.*) of the Holy Roman empire—a status that had been denied to the dukes by the Golden Bull of 1356. The title, however, was not recognized by the emperor Charles IV and was not juridically held by the Habsburgs until 1453, when the emperor Frederick III, himself a Habsburg, confirmed Rudolf's privilege and granted the title of archduke of Austria to his son Maximilian and his heirs. All males of the house of Habsburg bear this title; their daughters and wives are archduchesses. The title archduke of Austria also occurs in the royal style of the Bourbon kings of Spain, though they were not descended in the male line from their Habsburg predecessors.

ARCHELAUS (ARCHELAUS SISINES) (d. A.D. 17), king of Cappadocia, 36 B.C.–*c.* A.D. 14. His family, the hereditary priest-kings of Comana (*q.v.*) in Pontus, had long played an important part in the political life of Pontus and Cappadocia; in particular, they had schemed for possession of the Cappadocian throne. This ambition was finally realized in 36 B.C. when Mark Antony granted Archelaus the kingdom. After the battle of Actium (31 B.C.) Archelaus made his peace with Octavian and so retained his crown; and in 20 B.C. Cilicia Trachea, eastern Lycaonia and Armenia Minor were added to his kingdom. A marriage with Pythodoris, the widow of King Polemo of Pontus, brought him indirect control of most of Pontus.

During the reign of Augustus the subjects of Archelaus are said to have accused him at Rome on some charge against which Tiberius defended him. Archelaus showed Tiberius no gratitude for this service, ignoring him during the years of Tiberius' sojourn at Rhodes. When Tiberius succeeded Augustus (A.D. 14) Archelaus was lured to Rome and charged before the senatorial court with revolutionary conduct. The outcome is not known, but Archelaus, now very old, soon died (A.D. 17). On his death Cappadocia (though not Cilicia Trachea and eastern Lycaonia, where Archelaus' son Archelaus became ruler) was annexed as a Roman province. A decision on the part of Tiberius to incorporate Cappadocia in the Roman empire may have been the real cause of Archelaus' disgrace.

Archelaus is said to have spent much time at Elaeussa, a pleasant residence on the coast of Cilicia. He was an erudite man, if one may judge from the titles of the geographical works written by him and now lost. (R. H. St.)

ARCHELAUS (d. 399 B.C.), king of Macedonia from 413 to 399 B.C., was the son of Perdiccas II by a slave mother. He obtained the throne by murdering his uncle, his cousin, and his half-brother, the legitimate heir. Archelaus proved, however, to be a capable and beneficent ruler; Thucydides praises his work. He fortified cities, constructed roads, and organized the army; he endeavoured to spread among his people the refinements of Greek civilization, and he invited to his new capital at Pella many celebrated men, among them Euripides, Timotheus, Agathon, Choerilus, and Zeuxis; he celebrated games at Dium. He adopted a Persian coin standard and developed Macedonian trade. He seized Pydna in 410 and *c.* 400 put the pro-Macedonian oligarchic party into power at Larissa. He was assassinated by one of his favourites while hunting (399).

See F. Geyer, *Makedonien bis zur Thronbesteigung Philipps II* (1930). (F. W. WA.)

ARCHELAUS (5th century B.C.), Greek philosopher, was probably born at Athens (if so, he was the first Athenian to become a philosopher), though Diogenes Laërtius (ii, 16) gives the alternative of Miletus. He was a pupil of Anaxagoras (*q.v.*) and is said to have been the teacher of Socrates. Some argue that this is probably an attempt to connect Socrates with the Ionian school; others uphold the story. In general he followed Anaxagoras, but in his cosmology he went back to the earlier Ionians. He appears to have given a pre-eminent position to "air" and did not distinguish it from "mind," thus avoiding Anaxagoras' dualism. Out of this "air," by a process of thickening and thinning, arose cold and warmth, or water and fire, one passive, the other active. The earth and heavenly bodies are formed from mud, the product of fire and water, from which spring the lower animals and man. Man differs from animals in possessing a moral and artistic faculty.

No fragments of Archelaus remain; for the testimonies of the ancient authorities *see* H. Diels and W. Kranz, *Die Fragmente der Vorsokratiker* vol. 2, 6th ed. (1951–52).

ARCHER, THOMAS (1668/69–1743), English architect, whose style is closer to Roman baroque of the 17th century than was that of any of his English contemporaries, was the son of a Warwickshire squire. He was educated at Trinity College, Oxford, and, although often described as a pupil of Sir John Vanbrugh, he was so only in the loosest sense of the term. After leaving Oxford, Archer spent four years abroad. In 1705, under Queen Anne, he was appointed to the office of groom porter, a sinecure

which made him licenser of gambling places throughout the kingdom; in 1715 he obtained an even more lucrative sinecure, comptroller of customs at Newcastle upon Tyne. Most of his architectural designs belong to the period 1705–15. They include the north front of Chatsworth House, Derbyshire (1705), Heythrop Hall, Oxfordshire (*c.* 1705), a garden pavilion at Wrest Park, Bedfordshire (1711), Roehampton House, Surrey (1712), and the churches of St. Philip, Birmingham (1710), St. Paul, Deptford (1712), and St. John, Westminster (1714); the last two were the outcome of his appointment, under the act of 1711, as a commissioner for building 50 new churches. In 1715 he bought the manor of Hale, Hampshire, where he rebuilt the house and the church. He died in London on May 23, 1743.

Essentially dynamic, and incorporating direct borrowings from Bernini and Borromini, Archer's style shows neither the occasional medievalizing of Sir John Vanbrugh's work nor the dawning neoclassicism of Nicholas Hawksmoor's. Though less original than they, he held his own as an architect in the Europe of his time.

See Marcus Whiffen, *Thomas Archer* (1950); H. M. Colvin, *Biographical Dictionary of English Architects* (1954). (Ms. W.)

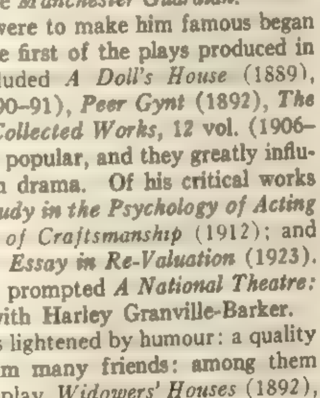
ARCHER, WILLIAM (1856–1924), Scottish drama critic, who influenced the revival of serious drama in England in the late 19th and early 20th centuries, was born in Perth on Sept. 23, 1856. While studying law at Edinburgh he began his journalistic career on the *Edinburgh Evening News*. After a world tour (1876–77), in 1878 he moved to London, and in 1879 became drama critic on the *London Figaro*. In 1884 he joined the *World;* his reviews for it and other periodicals were collected in *The Theatrical 'World,'* 5 vol. (1893–97). He was later drama critic on the *Nation*, the *Tribune*, and the *Manchester Guardian*.

The translations of Ibsen that were to make him famous began with *Pillars of Society* (1880), the first of the plays produced in England. Later translations included *A Doll's House* (1889), *Ibsen's Prose Dramas*, 5 vol. (1890–91), *Peer Gynt* (1892), *The Master Builder* (1893), and the *Collected Works*, 12 vol. (1906–12). Despite faults, these remain popular, and they greatly influenced the development of English drama. Of his critical works the best are *Masks or Faces? A Study in the Psychology of Acting* (1888); *Play-Making: a Manual of Craftsmanship* (1912); and *The Old Drama and the New: an Essay in Re-Valuation* (1923). His support for a national theatre prompted *A National Theatre: Scheme and Estimates* (1907), with Harley Granville-Barker.

The severity of his criticism was lightened by humour: a quality that, with his integrity, made him many friends: among them George Bernard Shaw, whose first play, *Widowers' Houses* (1892), he helped to recast on "Ibsenite" lines. Of his own plays, four were posthumously published; *The Green Goddess* (New York, 1921; London, 1923) was extremely successful and often revived.

"An energetic rationalist" (as J. M. Robertson called him), Archer wrote polemical essays for the Rationalist press (collected by Robertson in *William Archer as Rationalist*, 1925). Travels to the U.S., Spain, and India also resulted in books. He died in London on Dec. 27, 1924. (P. M. Y.; X.)

ARCHERFISH, the name given to several small fish because of their habit of projecting water from their mouths, thus wetting insects and knocking them into the water. The best-known species, *Toxotes jaculator*, inhabits the fresh waters of Java and other islands of the Malay archipelago.



BY COURTESY OF NEW YORK ZOOLOGICAL SOCIETY

ARCHERFISH (TOXOTES JACULATOR) SHOOTING DOWN A SPIDER

The archerfish, sometimes raised in home aquariums, reaches a length of 6 to 7 in. and can throw a jet of water 5 or 6 ft. with amazing accuracy. One of the Chaetodontidae (*Chelmon rostratus*) also inhabits Java and is, no doubt erroneously, credited with the same habit.

See also Aquarium: *Aquariums in the Home*.

ARCHERMUS, a Chian sculptor of the middle of the 6th century B.C. His father, Micciades, and his sons, Bupalus and Athenis, were all sculptors of marble, using, doubtless, the fine marble of their native land. The school excelled in draped female figures. Archermus is said to have been the first to represent Victory and Love with wings. This gives interest to a discovery made at Delos of a basis signed by Micciades and Archermus which was connected with a winged female figure in rapid motion (*see* Greek Art), a figure first regarded as the Victory of Archermus. Further investigation has discredited the idea that the statue belongs to the basis, which seems rather to have supported a sphinx.

ARCHERY, the shooting of arrows with a bow, is undoubtedly one of the oldest sports still being practised. The bow has been the most generally used and most widely dispersed of all weapons from its earliest days until the 16th century. Its importance in man's scheme of living is attested by the many family names—Archer, Arrowsmith, Bowman, Bownocker, Bowyer, Butts, Fletcher, Stringer, Yeoman—that have their origin in archery. After its replacement by firearms as a weapon of war, the bow became a favourite implement of sport.

For several decades the number of its followers has been steadily and rapidly increasing, both in the United States and the British dominions. Estimates have placed the number of archers in the United States and Canada in the second half of the 20th century at about 5,000,000, of whom 1,500,000 practice target archery and shooting for distance, and 3,500,000 field archery. The latter are reviving and developing the art of hunting with the bow and the crossbow (*q.v.*), their quarry being principally deer, wild pig and lesser animals; but moose, bear and mountain lion have fallen to the broadhead arrow.

Archery also is playing an important part in recreational work with both boys and girls in municipal playgrounds, in schools and colleges and among the boy and girl scout organizations and other youth groups. Archery also is highly valued in the process of physical therapy. In some schools for the blind both juniors and seniors are taught to shoot the bow accurately by sound. (J. W. An.)

HISTORY

The bow is probably man's first invention of a device in which energy can be accumulated slowly, stored temporarily and released suddenly under control and direction. The date of this invention—ranking in importance as a cultural advance with the development of speech and the discovery of the art of making fire—is at least 30 and more probably nearer 50 millenniums ago. The stout yew longbow, with its cloth-yard shaft, will ever hold its place of honour in English history for the victories it won at Crécy, Poitiers and Agincourt (*qq.v.*). For the American Indian, as for other aboriginals, the bow was the means of both subsistence and existence before and during the days of white colonization. South American Indians still use the bow for hunting and fishing. Pygmy tribes of Africa also depend on the bow for their livelihood, using poison on their arrows to render them lethal. (*See* also Bow and Arrow; Hunting and Fishing, Primitive.)

Many of the British monarchs of recorded history, up to and including Queen Victoria, practised archery. Of Henry VIII it was said by Raphael Holinshed in 1510 that "His Grace shotte as stronge and as greate a lengthe as anie of his garde." Roger Ascham (*q.v.*), archer, Cambridge scholar and tutor to Edward VI and Elizabeth I, was the author of *Toxophilus* (from the Greek *toxon*, "bow"), the first book on archery written in English (1545). In the dedication of his book to Henry VIII he said he had "written this English matter, in the English tongue, for Englishmen," so that the greatest possible number might read and learn.

Henry VIII in 1537 granted a patent to the Fraternity of St. George or Honourable Artillery company (H.A.C.; *q.v.*), and appointed Sir Christopher Morres and others as overseers of "the science of artyllary that ys to vyt, for long bowes, cross bowes, and handgunnes." Further patents were granted by James I in 1605 and Charles I in 1633, reinstating the company's practice

grounds, Finsbury fields, which had been partly fenced in by the owners. The fields extended roughly from Moorgate to Islington and in their heyday contained nearly 200 marks for shooting at rovers as well as numerous butts. By 1737, however, only 21 marks and 3 butts were left, one of the marks, a stone post named Scarlet, being still preserved at the armoury house of the H.A.C. When the H.A.C., about 1590, was discarding bows as war weapons, the Finsbury Archers, probably consisting of the remaining members of the H.A.C. archery section, started to flourish and held regular competitions until about 1761. The last of the Finsbury Archers joined the Toxophilite society when it was founded by Sir Ashton Lever in 1781.

The prince of Wales, afterward George IV, became patron of the "Tox" in 1787 and instituted the "prince's lengths," 100 yd., 80 yd. and 60 yd., of which distances the championship York Round still consists, and the revival of archery as a pastime then began. Nevertheless, although discarded as a weapon, the longbow, in skilled hands, was still superior to the inaccurate musket. During the American Revolution, Benjamin Franklin wrote to Gen. Henry ("Light Horse Harry") Lee, father of Gen. Robert E. Lee, wishing that bows could be added to the armament of the revolutionary army—"these were good weapons not wisely laid aside." While for centuries the longbow was the principal artillery weapon in England, in continental Europe the crossbow largely supplanted it, perhaps because the latter, though much slower in operation, needed less strenuous training in usage.

The Queen's bodyguard in Scotland is the Royal Company of Archers founded in 1676, whose headquarters are at Archers hall, Edinburgh.

In 1844 the first of the Grand National Archery (G.N.A.) meetings—the British championships—was held at York and the G.N.A. society became the governing body of the sport in the United Kingdom.

International competition in archery began with Anglo-French matches at Le Touquet prior to World War I, and in 1931, the Fédération Internationale du Tir à l'Arc (F.I.T.A.) was formed to conduct the annual world championship matches.

On Sept. 3, 1828, the oldest individual archery club in the United States, the United Bowmen of Philadelphia, was formed and had an uninterrupted existence for 60 years, until Oct. 1888. In 1932 the club was revived by Robert P. Elmer of Wayne, Pa. A physician and surgeon, his connection with archery began early in 1910; author of *Archery* (1933), his extensive research into this sport and his high degree of skill, which took him to national championships many times, made his influence on this sport so marked that thousands owed their enjoyment of archery to the inspiration he provided.

The National Archery association of the United States, the oldest organization of its kind in the U.S. that is national in scope and has had a continuous existence since its founding, was organized at Crawfordsville, Ind., in Jan. 1879. The official publication of the association is its monthly journal *"Tam," The Archers' Magazine*, counterpart of *The British Archer*. The National Field Archery association, founded 1939, is represented by *Archery Magazine*. The first U.S. national archery tournament was held in Chicago in Aug. 1879. With the exception of the war years (1917–18, 1942–45), a national tournament, to determine the champion archers for the year, has been held annually.

TOURNAMENTS

In target archery and field target shooting there are city, town, state, regional and national tournaments going on both indoors and outdoors all year round in the United States and Canada as well as in all other parts of the world where organized archery is in vogue. There are national and international mail matches as well as national and international competitions.

Target Shooting.—The regulation targets at all distances are 4 ft. in diameter (for the original prince's lengths the targets were 4 ft. at 100 yd., 3 ft. at 80 yd. and 2 ft. at 60 yd.) with four concentric rings, each 4.8 in. wide, and a central field or bulls-eye 9.6 in. in diameter. Colours and values (the "prince's reckoning") of the fields, going outward, are: gold, 9; red, 7; blue, 5; black, 3; white, 1. The target face is attached to a tightly compressed rolled mat, or bass, usually of straw, and it is supported on a stand with its centre 4 ft. above the ground. In tournament shooting, six arrows constitute an end, shot in two successive groups of three. The score for an end is expressed, for example, as "6–42," meaning that there were 6 hits, and that the scores for the individual hits totaled 42. U.S. men's championship shooting consists of two York rounds and two American rounds. In the York round, 144 arrows (in the United Kingdom the number of arrows is expressed in dozens) are shot; 12 ends at 100 yd.; 8 ends at 80 yd.; and 4 ends at 60 yd. The American round comprises 5 ends at 60, 50 and 40 yd. Highest total score for the four rounds determines the winner. In case of a tie, the score at the longest range wins. The U.S. women's championship is determined by the best total score in two National and two Columbia rounds. The former calls for eight ends at 60 and four at 50 yd.; the latter, four ends each at 50, 40 and 30 yd.

The British championships are based on the Double York round, for men, and the Double Hereford (24 ends at 80 yd., 16 at 60 and 8 at 50) for women. World championships for both men and women are based on two F.I.T.A. rounds, each consisting of (men) 36 arrows each at 90, 70, 50 and 30 m.; (women) 36 arrows each at 70, 60, 50 and 30 m. At 50 and 30 m. the target is 80 cm. in diameter, and at all distances the colours are divided into two zones each. Scoring is from one to ten. At the two shorter distances only three arrows are shot at an end. Target shooting was included in the Olympic games of 1900, 1904 and 1908 and bird shooting in the games of 1920 (*see* Olympic Games). Special rounds have been designed for club, high school and college tournaments.

Distance Events.—Flight shooting is an event scored on the basis of distance. No targets are used. Contestants are divided into classes by the pulling weight of their bows (see *Equipment and Use*, below). Clout shooting, as practised by the Royal Company of Archers and the Woodmen of Arden (1785) with traditional longbows, is at distances from 180 to 240 yd. (9 to 12 score). The 31-in. plain white target with a black centre is inclined at an angle of about 45° in the centre of five concentric circles drawn on the grass. The circle, 1½ ft. (called a foot) from the centre of the clout, scores 5 points; the 3-ft. circle (half bow) scores 4; 6 ft. (bow) 3; 9 ft. (bow and half) 2; 12 ft. (two bows) 1 point. An arrow which hits or touches the clout scores 6. Alternatively, scoring is by ends, the arrow nearest the centre of the clout winning the end. Two arrows only are shot at an end, the shooting being in two directions. Elsewhere, clout shooting is at a target 48 ft. in diameter, drawn on the ground in five zones, scoring as in standard target archery, with a small target or flag in the centre as an aiming mark.

The ancient sport of popinjay shooting, particularly popular in Belgium, consists of vertical shots at artificial birds of various sizes and values on perches at the top of a pole or church tower, usually 80 to 100 ft. up. In wand shooting, the target usually is a slat of soft wood two inches wide and projecting six feet from the ground.

Field Events.—A field round has been devised with 28 targets of various sizes, at different elevations and distances, and an established method of scoring.

HUNTING

Interest in archery in the United States increased after the publication, in 1878, of a book entitled *The Witchery of Archery* by Maurice Thompson, first president of the National Archery association. The book was a compilation of essays that had appeared in *The Atlantic Monthly*, *Field and Stream* and other journals, describing the idyllic hunting experiences, with bows and arrows, of the author and his brother, Will Thompson. During the years from 1911 to 1926 the regard for the sport in the U.S. and Canada was quickened further by the exploits and writings of Saxton Pope, San Francisco surgeon and professor at the University of California medical school, and his friend Arthur Young. Pope's interest was kindled by his associations with Ishi, last of the uncivilized Yana Indians, whose knowledge about the construction and use of bows

and arrows was transmitted to Pope, his mentor and guardian. Pope and Young undertook to make superior implements of the sport, designed for hunting, and to prove to their own satisfaction that the ancient weapon could successfully lay low the largest North American game animals. After killing grizzly bear and moose, and following Young's superb and courageous feat of killing a great Kodiak bear with a single arrow, Young and Pope went to Africa and added lions to their list. Pope's book *Hunting With the Bow and Arrow* (1923) helped to stimulate interest in the sport.

In the United States the National Field Archery association fosters sportsmanship in hunting, maintains and issues current information regarding state game laws as they apply to bow-and-arrow hunting, and confers the Art Young award upon those of its members who have taken big game with the bow. National archery associations in Great Britain and continental Europe have not concerned themselves with hunting with the bow and arrow.

As for the killing power and penetration of a hunting arrow there is practically no game existent which has not been killed with a bow and arrow. During the 1950s as a test of the killing power and penetration of an arrow a big game hunter, William Negley, with the help of a white hunter, Eric Rondgram, stalked and killed two African bull elephants in one day. Negley used a laminated wood and glass fibre bow of approximately 100 lb. pulling weight and steel-tipped broadheaded arrows approximately 29 in. in length. At a range of 10 to 15 yd., the arrows penetrated cleanly up to the feathers and the first elephant traveled less than 50 yd. before it fell. A second arrow at approximately the same range penetrated to the heart and killed the beast in a matter of seconds. Killing power and penetration such as this is comparable to the heaviest rifle bullet except that it does not render anywhere near the amount of shock that a bullet gives to the game. The arrow kills by penetration and hemorrhage while the rifle bullet kills mainly through shocking power.

With the ancient English longbows and their 700 to 800 gr. arrow the force of the arrow was sufficient to penetrate practically every means of defensive armour that was in existence at that time. As technical knowledge of the weapon increased it was found that lighter arrows with higher velocities gave considerably more penetration on live game than the heavier slower arrows of ancient times. This is the reason that the bows for target field and hunting are much lighter in drawing strength than in times past but in proportion so are the arrows; therefore the arrows get much greater velocities and penetrations are accordingly greater. The maximum effective range of the bow and arrow for hunting is 40 to 90 yd; the average kill of deer, however, is made at 30.5 yd.

Special bow fishing sets are in use on which a reel and line is attached to the handle of the bow and the end of the line is attached to a barbed arrow. The arrow is shot at fish on or near the surface of the water and the barbed point and the line permit both arrow and fish to be recovered.

EQUIPMENT AND USE

Bows.—In the process of shooting, the bow is held in an approximately vertical position. The ends of the bow are grooved to provide firm seats for the ends of the string. These grooves are called nocks. The same term is used for the slot or notch of the arrow which holds it in position on the string. The bow has a back, as well as a belly, which are, respectively, its convex and concave sides as it is drawn. The grip, or handle, is as a rule fitted to the hand similar to the so-called pistol grips of the modern rifle or shotgun. Immediately above the grip on one side is a narrow strip of leather which protects the bow from the rub of the arrow as it passes by. Part of the formation of the grip is a narrow shelf called the arrow rest which holds the arrow in place while it is being drawn back and over which the arrow slides when it is released. A loop or eyelet at each end of the string permits its being held securely in the two nocks one at each end of the bow. Bending the relaxed bow and sliding the loop toward the nock on each end until it drops into the nock is called bracing the bow. A bow is usually fitted with a string

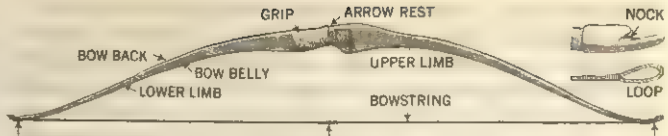


FIG. 1.—PARTS OF RECURVED BOW

of such length that its bracing height, that is, the distance from the string to the inner side of the grip, is an archer's fistmele (the width of the fist with fully extended thumb). This distance, depending on the archer's own dimensions, is somewhere between 6 and 8 in. When the bow is not in use it is unbraced, keeping it free from strain except when in actual use.

Bows used in target shooting weigh (force at full draw) from 20 to 60 lb., depending on the archer's strength. Length may be between 5 and 6 ft. Hunting bows range in weight between 50 and 100 lb., but some archers of Herculean brawn claim ability to manage up to 175 lb. Flight bows, for distance shooting only, weigh up to 90 lb. for regular style shooting, and up to 200 lb. in foot bows. Such a bow is strapped to the archer's feet. He shoots it while lying on his back, with his feet elevated to give the arrow the proper angle for maximum distance, and draws the string with both hands.

In the order of general preference, wooden bows are made of western yew (*Taxus brevifolia*), osage orange (*Maclura pomifera*), and dagame (*Calycophyllum candidissimum*). Other kinds of wood, including hickory, bamboo and red cedar, have been used as component materials in laminated bows. There also are bows of aluminum alloy made very similar in form to the orthodox wood bow, as well as bows of famous English and Swedish steels. Materials for covering the back of a bow, either as mechanical protection or to improve performance or durability, include parchment, rawhide, sinew fibre and silk fibre, the two latter in a matrix of glue. Many archers of the older order preferred to make their own wooden bows of the various popular woods as mentioned above. These they called self bows because they were as a rule made entirely of one piece with perhaps a backing and a facing of sinew or silk. However, as the sport progressed, so did the equipment. Skilled artisans began making bows of fibreglass and of laminated wood backed and faced with fibreglass. This is the modern composite bow, the efficiency of which is many times greater than the old time self bows and is the nearest approach to the traditionally famous oriental bow, the efficiency of which has not, as yet, been approached.

Arrows.—The parts of a target arrow are the nock, to which reference was made above; the shaft or stele, comprising the body of the arrow between the nock and tip; the shaftment, the portion of the stele to which the feathers are attached, extending to the crest; the crest, a distinctive, identifying arrangement of

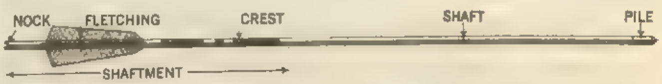

FIG. 2.—PARTS OF ARROW

coloured bands, encircling the stele a short distance forward from the fletching, or feathering; the footing, a section of hard dense wood comprising the foreshaft; and the pile, or metal cap, to give durability to the tip as it penetrates the target. A hunting arrow, or broadhead, differs from a target arrow in its greater weight, larger feathers and steel-bladed broadhead, sharpened to razor keenness.

The material preferred by many archers, when obtainable, and by experienced arrow makers is Scots pine (*Pinus sylvestris*; *see* PINE). This is the wood used almost exclusively by the arrow makers of England—Scots pine from Norway, preferably grown north of the Arctic circle. The "old deal" of story and tradition is usually Scots pine, a "deal" being a timber with a section at least 3 by 11 in., and "old" connoting that these timbers are frequently salvaged from old buildings being wrecked. Arrows of cedar and pine are usually footed with a tropical hardwood

called beefwood. Hunting arrows are usually made of birch.

In the United States most arrows for both target, field and hunting are made from Port Orford cedar, almost the only suitable wood obtainable. Arrows are also made of fibreglass, compressed Port Orford cedar and aluminum alloy (in the United Kingdom tournament arrows are made almost exclusively of aluminum alloy). These materials are easily composed so that the spine and stiffness of the arrow as well as its thickness can be readily maintained and for this reason arrows of these materials have been largely responsible for the tremendous increase in efficiency of the weapon not only in target shooting but in field archery and bow hunting as well. Target, field and hunting arrows also have undergone another change in that three feathered shafts have been superseded to a great degree by shafts which contain four, six and eight feathers. This gives them remarkable stability and has increased their range and accuracy to a considerable degree. Another innovation has been the substitution of plastic vanes cut out to approximately the same form as the feathers but giving the arrow a greater potential for velocity and low trajectory.

Bow Strings.—Traditionally, strings for bows were made of linen, usually shoemaker's thread. Modern bow strings usually are made of any one of a number of the Celanese products such as Fortisan and Dacron. These strings are extremely light and of fantastic strength in comparison with the traditional linen.

Accessories.—Many accessories are available to the archer such as special quivers for carrying hunting shafts as well as target arrows. Hunting quivers are designed to carry a number of broad-headed shafts and to dispense them with easy access. Some are attached to the bow to enable very rapid shooting. Target quivers differ slightly from hunting quivers as do the various leather accessories required by the archer in the form of arm guards, finger tabs and shooting gloves.

Drawing and Loosing.—Different peoples have developed a variety of methods of drawing and loosing the string. In 1885 E. S. Morse classified these as primary, secondary, tertiary, Mediterranean and Mongolian. The primary, according to Morse, is the simple pinch draw, in which the arrow is grasped at the nock between the thumb and first finger in a tight pinch, and drawn back. Obviously, only a weak bow can be thus drawn, since it depends upon the frictional force between the fingers and the arrow. Indian arrows have been found with the nock end enlarged to a knob, to permit a more secure grasp. The secondary draw is a modification of the primary, in which the second and third fingers rest upon and exert a direct pull on the string. In the tertiary draw, the first finger, in addition to grasping the arrow, crosses the string at an acute angle and pulls directly upon it, assisted by the second finger.

In the U.S., Canada and England, as in other countries in which the sport has taken hold, the Mediterranean loose is generally used. The string is drawn by hooking the first phalanx of each of

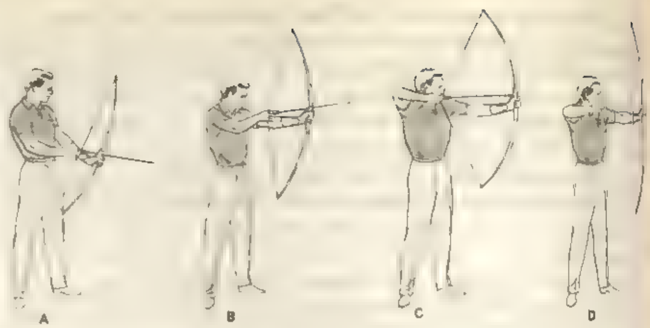
FIG. 3.—DRAWING FOR MEDITERRANEAN LOOSE DEMONSTRATED BY ARCHER EQUIPPED WITH ARM GUARD ON LEFT FOREARM AND SHOOTING GLOVE ENCASING THE FIRST THREE FINGERS OF THE RIGHT HAND



FROM PHOTOGRAPHS BY A. E. HODGKIN, "THE ARCHER'S CRAFT," FABER & FABER LTD., LONDON

FIG. 4.—SHOOTING TECHNIQUE: (A) NOCKING ARROW; (B) SIGHTING TARGET; (C) DRAWING BOW; (D) LOOSING ARROW

the first three fingers upon it, with the arrow nocked between the first and second fingers. In most Asian countries the Mongolian draw is practised. This is distinctly sophisticated as compared with the other kinds classified by Morse. The archer, wearing a protecting ring of horn, bone, ivory or jade upon his thumb, to protect it against injury from the great pressure of the string, hooks the thumb about the latter and locks the thumb with his first finger. The string is loosed by disengaging the finger and thumb.

Technique.—In describing the technique of shooting as practised in the U.S., Canada and England, it will be assumed that the archer is right-handed, and that he employs the Mediterranean loose. Equipped with an arm guard or bracer on his left forearm, to protect against painful string slap, and with a shooting glove which encases the ends of the first three fingers of his right hand in stiff, smooth leather thimbles, he stands astride the shooting line, facing at right angles to the direction in which he intends to shoot, with the target at his left. The string is engaged with the protected fingers of the right, while the handle of the bow is grasped in the archer's left hand. The arrow, with its nock fitted to the string, and with its shaft at right angles to the latter, rests against the arrow plate on the left side of the bow. As the archer raises the bow with his left hand, he draws the string with his right, and brings the drawn bow into an approximately vertical position. Without moving the body while drawing, he turns his head toward the target, and aims with his right eye, by a method described below. His right elbow is well elevated and the forearm transmits the force exerted by the muscles of the shoulder and upper arm through the fingers to the string. The string comes to rest pressing against his chin. When he is ready to loose the arrow, he continues to pull back, with deliberation, and, almost without conscious intent, allows his fingers to slide off the string. It is of utmost importance that there be no forward creep of the arrow prior to the loose, to assure uniformity of distance in successive shots. The bow hand must be steady, and remain immovable until the arrow is well on its way. Accuracy in the shooting of successive arrows at a target requires that the individual arrows in the set have great uniformity of dimensions, weight, stiffness, balance and finish, and that the bow be unchanging in weight, so that the total energy for propelling each shaft may be the same.

Assuming perfect execution of the draw and loose, hitting a distant mark requires a certain angle of elevation of the drawn arrow. This angle is found by a few trial shots, after which it may be reproduced by sighting over the tip of the arrow at some selected point, called the point of aim, on the ground, on the target or in the landscape behind the target. To identify the point of aim an artificial marker may be used. Many archers prefer to use a bow sight which permits aiming directly on target. The sight is attached to the bow just above the handle and has a small bead or pin which can be moved up or down for elevation and can be moved to either side to make allowance for lateral adjustments required by either wind or a variation in the stiffness or spine, of the archer's arrow.

In field shooting and in hunting, where distances to targets or marks are unknown, and terrain may be rough, obviously no point

of aim marker can be used, nor is there much virtue in using a sight at unknown distances. Instinctive aiming then becomes necessary, unless it is done with the aid of markings on the bow after the distance has been estimated. Proficiency in marksmanship both at the target and in hunting is acquired only through patient, careful practice.

Arrows and Their Flight.—An arrow is said to be properly matched to a bow if, when it is well loosed, it passes the bow smoothly, without impact against the arrow plate, and takes off steadily on its flight. When the arrow is loosed, the lateral forces upon it cause it to bend, and to be set in oscillation about two nodal points, each approximately one-fifth to one-fourth the distance from the end of the shaft. The period of oscillation must be so related to the time of passage of the bow that the instantaneous displacement of the part of the shaft opposite the arrow plate is outward. When this condition obtains, the arrow remains clear of the bow in passing, and flies precisely in the vertical plane defined by the line of aim. An arrow that is too stiff or too limber oscillates either too rapidly or too slowly for proper synchronization with its time of passage, which results in its impinging on the arrow plate somewhere along the shaft, with consequent deflection.

That property of an arrow which an archer calls spine combines the elements of both mass and stiffness. These factors determine the period of oscillation, and mass determines the time it takes from the instant the arrow is loose, to clear the bow. The arrow must bend instantly when it is released to oscillate and curve itself around the bow. Since this time interval also depends on the performance of the bow the concept of spine involves not only the arrow but also the bow that shoots it. Thus an arrow with suitable spine for one bow may not have the correct spine for another.

In order to have some measurable scale for reconciling the relationship of the proper spine of an arrow to the bow that shoots it, spine testers have been developed in which an arrow shaft is placed upon two upright posts 26 in. apart and a two-pound weight is hung in the centre of the shaft. The refraction or measurable distance which the arrow bends is an indication of both its stiffness and its ability to return to normal straightness.

The location of the centre of mass, or balance point of an arrow, becomes especially important when there is a side wind or quartering wind. In addition to the drift in the direction of the wind, the arrow is caused to yaw; *i.e.*, its axis deviates from the direction of its flight. This gradual rotation about a vertical axis through its centre of mass, with the point moving into the wind, is caused by the unbalanced forces produced by the pressure of the wind behind and in front of the balance point, respectively. It is accentuated by large vanes, and by a centre of mass located forward. Conversely, yawing caused by wind is minimized by small feathers and a centre of mass located well back. In strong cross winds an arrow may strike the target at an angle so large with respect to its direction of flight that it is broken on impact.

ARCHES, COURT OF: *see* ECCLESIASTICAL LAW (ENGLISH).

ARCHIANNELIDA, a mixed group of aberrant segmented worms regarded as a subunit of the class Polychaeta. *See* ANNELIDA: *Polychaetes.*

ARCHIAS, the name of several Greek poets whose epigrams are in the *Greek Anthology*. It has been suggested that some of these poems were written by the poet Aulus Licinius Archias of Antioch, who when accused of illegally assuming Roman citizenship was successfully defended by Cicero in his speech entitled *Pro Archia*.

See T. Reinach, *De Archia poeta* (1890).

ARCHIDAMUS, the name of five Spartan kings of the Eurypontid house.

ARCHIDAMUS I, in Herodotus (viii, 131) grandson of Theopompus, therefore near the beginning of the 7th century B.C. Pausanias (iii, 7; not to be reconciled with Herodotus) mentions a somewhat later Archidamus, whose reign is said to have been peaceful.

ARCHIDAMUS II (5th century B.C.), son of Zeuxidamus who died young, succeeded his grandfather Leotychides, who was exiled soon after the Persian Wars, but Archidamus' reign seems to be counted from his death in 469. After the disastrous earthquake of 464, when the Messenians revolted, Archidamus organized the defense of Sparta, but for the next 30 years all known operations of the Spartan army were commanded by members of the other royal house. When Archidamus next appears, in 432, Thucydides presents him as a prudent statesman of great authority, who wished to postpone the war with Athens but was overborne. He led the Peloponnesian invasions of Attica in 431, 430 and 428, and the operation against Plataea in 429. He probably died in 427.

ARCHIDAMUS III (4th century B.C.), king of Sparta (360–338) in succession to his father Agesilaus II. He led the relief force sent to Boeotia after the Theban victory at Leuctra in 371, and commanded during the confused fighting in the Peloponnese which followed it. Isocrates' pamphlet *Archidamus* represents him as resolutely refusing to recognize the independence of Messenia. He defeated the Arcadians in 367 at the "tearless battle," so called because no Spartan was killed; suffered a reverse at Cromnus in 364; and showed great courage in the defense of Sparta against Epaminondas in 362. Succeeding to the throne in 360, he supported the Phocians against Thebes in the Sacred War of 355–346. Sent with a mercenary army to help Tarentum against its Italian neighbours, he fell with most of his force at Mandorium in 338, allegedly on the day of the battle of Chaeronea.

ARCHIDAMUS IV (3rd century B.C.), son of Eudamidas I. The precise dates of his reign are unknown. In 294 he was defeated by Demetrius Poliorcetes (*q.v.*) at Mantinea, and Sparta was saved only because Demetrius was called away by the activities of Lysimachus and Ptolemy.

ARCHIDAMUS V (3rd century B.C.), son of Eudamidas II, fled to Messenia after the murder of his brother Agis IV in 241 (*see* AGIS). In 227 he was recalled by Cleomenes III, but was murdered soon afterward. Plutarch blames the murderers of Agis, Polybius accuses Cleomenes himself. Both are heavily prejudiced, but it seems that Cleomenes took no steps against the murderers.

(A. As.)

ARCHILOCHUS (fl. 7th century B.C.), was the earliest writer of elegiac and personal lyric poetry in Greek of whose works any considerable portion has survived. The ancient Greeks regarded him as one of their greatest poets and the extant fragments strongly suggest that they were right. He was born on the island of Paros, perhaps *c.* 710 B.C., and was a bastard (his father was the founder of a Parian colony on the island of Thasos and his mother may have been a Thasian), but this would probably have made little difference to him had he not been spurned as a suitor by a certain Neobule. According to the story (based presumably on his own words), his fury at this insult expressed itself in verse of a savagery which drove her and her father Lycambes to suicide.

It was perhaps as a result of this rebuff that Archilochus went to live in Thasos, where he seems to have become a soldier of fortune, later serving in Thrace and other places and composing his poetry as he served. Pindar's main reference to him suggests that his life was never very prosperous. He may have lived to witness the solar eclipse in 648.

He was the first Greek poet whose work has survived to employ the elegiac couplet and the various iambic and trochaic metres (from the dimeter to the tetrameter), as well as sundry combinations of dactylic elements with iambic or trochaic (the so-called "asynartete" metres), some of which were taken over into Latin by Horace. He was also the first European writer to make his personal experiences and feeling the main subject of his poems, and he may fairly be called the originator of individualism in literature. An attempt has been made to reconstruct the main outlines of Archilochus' epodes, and there is no doubt that the stories

of the ferocity with which he attacked Neobule and her father (not to mention other eminent Thasians and Parians) are fully justified; but the popularity and influence of his poems in later times testify to the universality, as well as to the force and originality, of his genius. This is perhaps most evident in the admiration for his works expressed by Horace. The fragments, to which papyrological discoveries have made considerable additions, show that he was among the most skilful handlers of the Greek language and a metrical innovator of the highest ability and importance.

The fragments were edited by F. Lasserre and A. Bonnard, with a French translation, in the Budé series (1958).

ARCHIMANDRITE, the honorary title of certain unmarried priests in the Eastern Orthodox Church, meant in the Byzantine period the superior of a monastery (now called hegumenos) and then of a federation of monasteries. Archimandrites rank next after bishops, and use certain episcopal insignia. *See* also ABBOT.

See J. Pargoire in F. Cabrol, *Dictionnaire d'archéologie chrétienne et de liturgie*, vol. i, col. 2739–2761 (1907). (H. M. W.)

ARCHIMEDES (*c.* 287–212 B.C.), Greek mathematician and inventor, was born at Syracuse, in Sicily. He was the son of Pheidias, an astronomer, and was closely associated with, if not related to, Hieron II, king of Syracuse, and Gelon his son. He studied at Alexandria and doubtless met there Conon of Samos, whom he admired as a mathematician and cherished as a friend. On his return to his native city he devoted himself to mathematical research.

Archimedes himself set no value on the ingenious mechanical contrivances which made him famous, regarding them as beneath the dignity of pure science and even declining to leave any written record of them except in the case of the *sphairopoiia* ("sphere making"; *see* below). As these machines impressed the popular imagination, however, they naturally figure largely in the traditions about him. Thus he devised for Hieron engines of war which almost terrified the Romans, and which protracted the siege of Syracuse for three years. There is a story that he constructed a burning mirror which set the Roman ships on fire when they were within a bowshot of the wall. It is probable that Archimedes had constructed some such burning instrument, though the connection of it with the destruction of the Roman fleet is more than doubtful. More important is the story of Hieron's reference to him of the question whether a crown made for him and purporting to be of gold did not actually contain a proportion of silver. According to one story, Archimedes was puzzled till one day, as he was stepping into a bath and observed the water running over, it occurred to him that the excess of bulk occasioned by the introduction of alloy could be measured by putting the crown and equal weights of gold and of silver separately into a vessel of water and noting the differences of overflow. He was so overjoyed when this happy thought struck him that he ran home without his clothes, shouting "*eureka, eureka*" ("I have found it, I have found it"). Similarly his pioneer work in mechanics is illustrated by the story of his having said "give me a place to stand and I will move the earth." Hieron asked him to give an illustration of his contention that a very great weight could be moved by a very small force. He is said to have fixed on a large and fully laden ship and to have used a mechanical device by which Hieron was enabled to move it by himself; but accounts differ as to the particular mechanical powers employed. The water screw which he invented (*see* ARCHIMEDES, SCREW OF) is used even now in Egypt for the purpose of irrigating fields.

Archimedes died at the capture of Syracuse by Marcellus, 212 B.C. In the general massacre which followed the fall of the city, Archimedes, while engaged in drawing a mathematical figure on the sand, was run through the body by a Roman soldier. No blame attaches to the Roman general, Marcellus, since he had given orders to his men to spare the house and person of the sage, and in the midst of his triumph he lamented the death of so illustrious a person, directed an honourable burial to be given him and befriended his surviving relatives. In accordance with the expressed desire of the philosopher his tomb was marked by a sphere inscribed in a cylinder, the discovery of the relation between the surface and volume of a sphere and its circumscribing cylinder being regarded by him as his most valuable achievement. When Cicero was quaestor in Sicily (75 B.C.) he found the tomb of Archimedes, near the Agrigentine gate, overgrown with thorns and briers.

Works.—The range and importance of the scientific labours of Archimedes will be best understood from a brief account of those writings which have survived; and it need only be added that his greatest work was in geometry, where he so extended the method of exhaustion as originated by Eudoxus and followed by Euclid that it became in his hands, though purely geometrical in form actually equivalent in several cases to integration, as expounded in the first chapters of modern textbooks on the integral calculus. This remark applies to the finding of the area of a parabolic segment (mechanical solution) and of a spiral, the surface and volume of a sphere and of a segment thereof and the volume of any segments of the solids of revolution of the second degree.

The extant treatises are as follows:

1. *On the Sphere and Cylinder* is a treatise in two books, dedicated to Dositheus, and deals with the dimensions of spheres, cones, "solid rhombi" and cylinders, all demonstrated in a strictly geometrical method.

2. *The Measurement of the Circle* is a short book of three propositions, the main result being obtained in proposition 2, which shows that the circumference of a circle is less than $3\frac{1}{7}$ and greater than $3\frac{10}{71}$ times its diameter.

3. *On Conoids and Spheroids* is a treatise in 32 propositions, on the solids generated by the revolution of the conic sections about their axes, the main results being the comparisons of the volume of any segment cut off by a plane with that of a cone having the same base and axis.

4. *On Spirals* is a book of 28 propositions. Propositions 1–11 are preliminary, 13–20 contain tangential properties of the curve now known as the spiral of Archimedes and 21–28 show how to express the area included between any portion of the curve and the radii vectores to its extremities.

5. *On Plane Equilibria or Centres of Gravity of Planes* consists of two books and may be called the foundation of theoretical mechanics, for the previous contributions of Aristotle were comparatively vague and unscientific. In the first book there are 15 propositions, with 7 postulates; and demonstrations are given, much the same as those still employed, of the centres of gravity (1) of any two weights; (2) of any parallelogram; (3) of any triangle; (4) of any trapezium. The second book in 10 propositions is devoted to the finding of the centres of gravity: (1) of a parabolic segment; (2) of the area included between any two parallel chords and the portions of the curve intercepted by them.

6. *The Quadrature of the Parabola* is a book in 24 propositions containing two demonstrations that the area of any segment of a parabola is $\frac{4}{3}$ of the triangle which has the same base as the segment and equal height.

7. *On Floating Bodies* is a treatise in two books, the first of which establishes the general principle of hydrostatics, and the second discusses with the greatest completeness the positions of rest and stability of a right segment of a paraboloid of revolution floating in a fluid.

8. *The Sand Reckoner* is a small treatise addressed to Gelo, the eldest son of Hiero, expounding, as applied to reckoning the number of grains of sand that could be contained in a sphere of the size of our "universe," a system of naming large numbers according to "orders" and "periods."

9. *The Method*, addressed to Eratosthenes, is a treatise of vital interest, since in it Archimedes explains how he first arrived at many of his important results by means of mechanical considerations, namely, by weighing an indefinite number of elements of one figure against similar elements of another. This treatise, formerly supposed to be lost, was discovered in 1906 by J. L. Heiberg in a palimpsest at Istanbul and now forms part of Heiberg's Greek

text of Archimedes.

10. *A Collection of Lemmas,* consisting of 15 propositions in plane geometry, has come down through a Latin version of an Arabic manuscript; it cannot, however, have been written by Archimedes in its present form, since his name is quoted in it more than once.

Lastly, Archimedes is credited with the famous "cattle problem" enunciated in the epigram edited by Gotthold Lessing in 1773, which purports to have been sent by Archimedes to the mathematicians at Alexandria in a letter to Eratosthenes. Of lost works by Archimedes there are references to seven: (1) investigations on polyhedra mentioned by Pappus; (2) *Principles,* a book addressed to Zeuxippus and dealing with the naming of numbers on the system explained in the *Sand Reckoner;* (3) *On Balances or Levers;* (4) *On Centres of Gravity;* (5) the *Catoptrica,* an optical work from which Theon of Alexandria quotes a remark about refraction; (6) *On the Calendar;* (7) *On Sphere Making,* in which Archimedes explained the construction of the sphere which he made to imitate the motions of the sun, the moon and the five planets in the heavens. Cicero actually saw this contrivance and described it.

The *editio princeps* of the works of Archimedes with the commentaries of Eutocius is that printed at Basel (1544) in Greek and Latin by Hervagius. A Latin version was published by Isaac Barrow in 1675. Torelli's edition (1792) remained the best Greek text until the definitive text edited, with Eutocius' commentaries, Latin translation, etc., by J. L. Heiberg (1800–81; 2nd ed., 1910–15) superseded it. T. L. Heath edited *The Works of Archimedes* in modern notation, with introduction, etc. (1897) and also, as a supplement, the newly discovered *Method* (1912). Modern translations are those of F. Peyrard, in French (1808); E. Nizze, with notes, in German (1824); P. ver Eecke, *Les Oeuvres Complètes* (1921); A. Czwalina-Allenstein, *Kugel und Zylinder* (1922), *Über Spiralen* (1922), *Die Quadratur der Parabel* (1923), *Über Paraboloide, Hyperboloide und Ellipsoide* (1923), *Über schwimmende Körper und die Sandzahl* (1925).

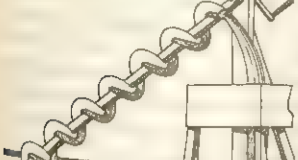
(T. L. H.; B. L. v. d. W.)

ARCHIMEDES, SCREW OF, a machine for raising water, said to have been invented by Archimedes for the purpose of removing water from the hold of a large ship that had been built by King Hieron II of Syracuse. It consists of a water-tight cylinder which encloses a helix, and has its lower open end placed a half turn in the water. The water is therefore lifted mechanically by the turning of the machine.



ARCHIMEDES' SCREW, INVENTED BY THE GREEK MATHEMATICIAN (c. 287–212 B.C.)

Other forms have the helix revolving free in a fixed cylinder, or consist simply of a tube wound helically about a cylindrical axis. The same principle is sometimes used in machines for handling wheat, etc.

ARCHIPENKO, ALEXANDER (1887–1964), Russian-American sculptor and painter, one of the pioneers of modern sculpture, was born in Kiev, May 30, 1887. After studying in Russia, he attended the École des Beaux-Arts in Paris (1908), where he came into contact with the Cubists. Representation of the human figure was subordinated in his works to the formal composition of voids and solids.

In "Walking Woman" (1912), holes were punched in face and torso, and concavities substituted for the convexities of the lower legs. "Boxing Match" (1913) attempted to convey the brutal energy of the sport in nonrepresentational, machinelike cubic and ovoid forms. As early as 1912, Archipenko executed the first of his famous "Medranos," circus figures in multicoloured glass, wood and metal, defying traditional use of materials. His later works were less revolutionary in form and conception. After a sojourn in Berlin, he settled in the United States in 1923, where he became a lecturer and teacher. He died on Feb. 25, 1964, in New York city.

(L. W. N.)

ARCHITECTURAL DRAWING: *see* Drawing, Engineering; Architectural Rendering.

ARCHITECTURAL EDUCATION. The functions of the architect are manifold and highly technical. He must be expert in the planning of buildings; *i.e.,* acquainted with the practical requirements of various kinds of structures, often complex, such as factories and commercial buildings, hotels, theatres, hospitals and schools. He must know how to arrange the several parts of these buildings in the most economical and convenient manner, for planning is the basis of architecture. He must understand both traditional and modern methods of building construction, and appreciate the importance of mechanization and of industrial techniques.

Though applied science is involved in architectural practice, it is always part of the means and never the end of architecture; the architect makes the technical sciences the servants of his art. Not only methods of construction, but surveying, sanitation, hygiene, heating, lighting, ventilation and acoustics come within this category, as do such ancillary subjects as the law and finance of building. The training of the architect also must include the study of perspective, skiagraphy, rendering (*see* Architectural Rendering) and the preparation of working drawings (*see* Drawing, Engineering). In addition, study of materials—their practical characteristics and the effects that can be obtained from them—is an essential element in the architect's education, since materials determine the durability and appearance of structures. Application of all this varied knowledge is implied in architectural design, with which the architect is primarily and ultimately concerned.

Architectural design involves thinking and visualizing simultaneously in three dimensions—plan, section and elevation—in such a way that the resultant composition is expressive and beautiful. For this is required efficient creative ability that no system of training can generate. Training, however, can make possible its fullest development, can direct it along the most profitable lines and can place at its disposal the accumulated experience of the past. These are the objects with which the systems of architectural education are chiefly concerned.

The study of architecture should be preceded by a liberal education, hence the modern tendency is for schools of architecture to require from candidates for admission evidence of a broad nontechnical education; in a number of cases liberal arts studies also are pursued during at least the earlier portion of the professional course. Architectural education in the United States is administered principally by universities, and in Europe and the British commonwealth either by universities or by institutions virtually of university rank, such as the École des Beaux-Arts in Paris, the High School of Architecture in Rome and the Viennese academy.

Teaching of architecture in some institutions is conducted in association with painting and sculpture; in others the curriculum has a strong mathematical bias; in still others emphasis is laid on preserving and developing traditional methods of design. In nearly all countries, however, architectural education is considered to be the responsibility of the practising profession. In France, where academic education was instituted in the 17th century, the most eminent architects have undertaken educational obligations. Elsewhere in the early days of architectural schools the attempt was made to divide the profession into two classes—theoretical nonpractising teachers and architects who practised and did not teach. But architecture rarely could be taught successfully by theorists, and modern architectural education has come to be placed largely in the hands of practising architects. Nevertheless, conditions of practice must inevitably differ from

those of theoretic training, and in order to effect a transition between the two, most systems of architectural education provide for some actual experience in practice.

Continental Europe.—*Italy.*—The emergence of Italy as a unified nation in the 19th century coincided with the end of the period in which training of architects was undertaken by independent academies founded during and after the Renaissance. Henceforth the state assumed the responsibility, establishing two types of institutions to discharge it: schools of civil engineering and institutes of fine arts. Architecture was taught in the first as a structural science and in the second as an art of design associated with painting and sculpture. But by divorcing the study of modern constructional methods from that of composition, two separate classes of experts were created, structural engineers and architectural decorators, the former well equipped in the scientific technique of building but unable to use their knowledge as artists, the latter insufficiently trained in the material and practical aspects of their subject but accomplished in superficial design. As was inevitable in an age that exalted applied science and mechanical skill, structural engineers soon acquired an authority superior to that of architects, with consequences unfortunate for both the latter and their work. To remedy this situation a number of proposals and tentative experiments were made in the latter half of the century resulting in the establishment in 1919 of the High School of Architecture in Rome, a school of university rank that requires from entrants a liberal education and previous artistic training. It is the central institution for architectural education in Italy. Its professional course extends over five years and the curriculum provides for a properly adjusted balance of scientific and aesthetic studies. There are also leading institutions in Milan, Florence and Venice, and an altogether happier relationship has developed between the engineer and the architect; the collaboration was reflected in some magnificent achievements in reconstruction after World War II.

France.—State control of French architectural education dates from the foundation under Jean Baptiste Colbert of the Royal Academy of Architecture in 1671. This control, temporarily interrupted by the Revolution, was resumed in 1795, when in the newly created Institut de France an academy of fine arts, embracing architecture, was included. The private school of architecture set up by J. D. Leroy during the Revolution was taken under the protection of the institute, incorporated with the other art schools administered by that body, and finally, in 1816, accommodated on the site it still occupies, under the name, famous throughout the world, of École des Beaux-Arts (*see* BEAUX-ARTS, ÉCOLE DES). Under Napoleon III a decree of 1863 drastically altered the organization of the school, restricted the authority of the Académie des Beaux-Arts over it and introduced the modern regime. The school became directly a state institution with a director at its head appointed by the minister of fine arts. Its professors were nominated by the educational council and its courses extended and increased in number. In addition to the professors who lectured, *patrons*, or heads of ateliers, were appointed to the staff. The problem of style, which the dissensions of the romanticists and classicists had made an acute issue, was solved by eliminating it. Periods were no longer prescribed or proscribed.

All designs were judged by logical standards, and matters of taste were permitted to remain matters of taste. Compositions might be submitted in any style or in no style at all; their value would be assessed upon grounds that had nothing to do with the question of architectural idiom.

The teaching of architecture in France is still centralized in the École des Beaux-Arts, and the 13 regional schools in Lille, Rouen, Rennes, Lyons, Marseilles, Strasbourg and other cities are still branches of the Paris *école,* working on the same programs and conducting simultaneously the same competitions among their students. Leading modern architects, and the students as well, are becoming increasingly critical of the system imposed by the École des Beaux-Arts, and radical changes are expected.

The course of studies leading to the government diploma in architecture is elaborate and difficult. Students are prepared for the *école* entrance examination either in certain ateliers that devote themselves exclusively to this task or in large ateliers concerned mainly with the subsequent design work of the course. The examination comprises tests in design, drawing and modeling, mathematics, descriptive geometry, science and the history of art. After admission to the *école* the work falls into three sections: second class; first class; and the great prize competitions, of which the most important is that for the Grand Prix de Rome. Before promotion from the second to the first class, further tests must be passed in science, mathematics, geometry, perspective, construction and design. Concluding the studies in the first class there are final examinations in physics, chemistry, building laws, regulations and design. On the results of these the diploma is awarded after a course that usually extends over at least four to five years.

In addition to the state system, the École Spéciale d'Architecture, founded as a private venture in 1865, also grants a diploma that has been officially recognized since 1934.

Other European Countries.—Architectural education in western Germany, the Netherlands, Switzerland and Scandinavia is given by a variety of institutions—technical institutes of university rank, colleges and schools of applied art. The duration of courses is generally four to five years. After World War I modern European architects turned the educational system toward more functional design and a closer contact with contemporary productive methods. In Germany the Staatliche Bauhaus at Weimar (later at Dessau) had started to combine artistic training in modern design with practical training in crafts and building. This method has since influenced various architectural curriculums in and outside Germany, most thoroughly perhaps those of the Chicago Institute of Design (in 1949 absorbed by the Illinois Institute of Technology) and the Hochschule für Gestaltung opened at Ulm in 1955 (*see* also BAUHAUS). After the end of the Nazi regime the Institutes of Technology at Munich and Stuttgart regained their former prestige, although the role of other German schools, especially those of the *Kunstgewerbe* ("applied art") category, should not be underestimated.

Belgium provides for the training of architects in municipal academies of fine arts and in the professional schools known as the St. Luc academies. The Copenhagen academy provides a complete training for architects in Denmark, where the trade and professional schools, as in many European countries, are also important. Norway has made architectural education a state responsibility and a diploma is awarded in the Technical university at Trondheim. The organized training of Swedish architects is largely in the hands of the Institutes of Technology at Göteborg and Stockholm and of the Stockholm academy. In the Netherlands, schools at Delft and Amsterdam, and in Switzerland the Eidgenössische Technische Hochschule at Zürich, bear the main responsibility for training architects. The technical colleges in Austria are of university rank, and some give instruction in architecture. The Viennese Academy of Plastic Arts carries the education of students to a higher stage. In Ireland, University college, at Dublin, provides a course of three years in the school, followed by two spent in gaining practical experience, leading to the degree of Bachelor of Architecture. In Spain architectural training is given at the High School of Architecture attached to Madrid university, and at the Barcelona school.

Great Britain and the Commonwealth.—So long as English architects followed, as they did throughout the 17th and most of the 18th centuries, a single architectural tradition, and were content simply to develop it, and so long as the technical requirements of building were relatively simple, the pupilage system was adequate for the education of the profession. But the foundations of this world of commonly shared artistic convictions and practice began to be undermined when architects ceased to be satisfied with giving to the style of the Italian Renaissance a national character, and sought their inspiration in the antique origins of that style.

The study of Roman forms was followed by the discovery and copying of Greek, with the result that by the end of the 18th century the architectural student had lost his certainty of outlook. The variety of the prospects opened to him was further extended by the romantic movement. This, finding its architectural

expression in the Gothic revival, completed the confusion that had been initiated by archaeological research. The orderly development of English architecture was lost in a "battle of the styles," and the offices of practising architects, which had formerly served as the instruments of a common professional education, were reduced to dissociated units, each the vehicle of a personal concept of architecture. Finally, by the latter half of the 19th century, the practical requirements of building and the methods of construction employed had greatly increased in range and complexity, so that the technical equipment required for their mastery alone had become more than could be supplied by the ordinary architect's office.

All these factors combined to render the pupilage system no longer a satisfactory method of education. Institutional training had to take its place, and during the 20th century considerable progress was made in establishing and developing schools of architecture devoted to giving systematic courses of instruction in the whole technique of building, and endeavouring to replace the lost traditions of design by teaching based on rational principles.

There are in Great Britain four types of institutions giving instruction in architecture: technical schools; schools of art; independent professional schools; and universities. With few exceptions the first two offer courses of not more than three years duration, and the classes are in many cases held at night. The main function of schools of this order, which are usually under municipal control, is to supplement the pupilage system in those parts of the country, still of considerable extent, in which it yet survives. But the real qualifying work is undertaken by schools with a full daytime course extending over five or more years. The five-year course was introduced at the Liverpool University school in 1920, when the Architectural Association school in London adopted one of similar character. Such courses, when taken at a university by matriculated students, lead to a degree; when taken at an institution of nonacademic rank, to a diploma similar to that granted by the universities to graduates who have not matriculated.

Among the principal schools of architecture in England are those of the Architectural association and of Liverpool university. In Scotland the Glasgow school has the greatest number of students; through its affiliation with the University of Glasgow, after 1925 it was able to offer a B.S. degree with honours in architecture. In other countries of the commonwealth have been founded university schools of architecture that conduct courses of study varying from three to five years in length. Particularly in Canada and Australia, English influence in architectural education is accompanied by American, with the result that the complete transition from pupilage to training under university auspices seems likely to be most rapid in those countries.

The normal curriculum of the larger qualifying schools in Great Britain provides for the study of design and construction throughout five years. In addition to the work done in the school studios, courses of lectures are given on the theory of design and construction, history of architecture, descriptive geometry, skiagraphy, perspective, sanitation, hygiene, surveying, specification, estimates, contracts, professional practice and other cognate subjects. Provision is sometimes made for specialization during the last two years, the course being then taken with honours in either design or construction to meet the demand for advanced qualifications in both spheres. In certain of the academic schools the first year program of study includes such liberal arts subjects as languages, social history and literature. A portion of the concluding part of the course is always spent by the students in gaining practical office experience. Town planning is a recognized subject in most schools of architecture.

From its foundation in 1834 the Royal Institute of British Architects (R.I.B.A.) has been the supreme controlling authority of the profession throughout the commonwealth and empire. Though the R.I.B.A. has never undertaken the teaching of architecture, it performed a notable service in raising the general level of professional knowledge by setting up, in the latter half of the 19th century, a centralized system of examinations. Through its board of architectural education it delegated to certain approved schools the task of qualifying candidates for admission to the institute, maintaining its own centralized examinations only for students not seeking entry through scholastic channels.

The following schools of architecture are recognized for exemption from the R.I.B.A. final examination (except in the subject of "Professional Practice"): Robert Gordon's Technical college, Aberdeen; Birmingham School of Architecture; College of Art and Crafts, Brighton; Royal West of England Academy School of Architecture, Bristol; Cambridge university; Canterbury College of Art; Welsh School of Architecture, Cardiff; University college, Dublin; School of Architecture, Dundee; Edinburgh university; Edinburgh College of Art; School of Architecture, Hull; Leeds School of Architecture; Leicester College of Art; Liverpool university; London university; Architectural association, London; Northern Polytechnic, London; the Polytechnic, Regent street, London; Hammersmith College of Art; Kingston-upon-Thames School of Arts; Manchester university; Durham university; Nottingham university; Oxford university; College of Art, Portsmouth; Sheffield university; Municipal college, Southend-on-Sea; Glasgow School of Architecture; University of Adelaide; University of Melbourne; Melbourne Technical college; University of Queensland; Perth Technical college; Gordon Institute of Technology; University of Sydney; New South Wales university; University of Manitoba; McGill university; University of Toronto; Auckland University college; University of Cape Town; University of Pretoria; University of the Witwatersrand; and Shri J. J. School of Art, Bombay. About a dozen other schools of architecture are recognized for purposes of exemption from the R.I.B.A. intermediate examination.

In both classes the maintenance of the requisite standard is assured by the periodic inspection of a visiting board, appointed by the R.I.B.A. board of architectural education, which reports to the institute on the work of the various schools granted or applying for exemption. The institute further requires to be satisfied as to the preliminary general education of students, and evidence must be submitted upon this point in each individual case. The R.I.B.A., with its provincial allied societies, has also instituted a scheme of maintenance scholarships which are competed for annually and are tenable at schools of architecture recognized by the institute. A number of valuable prizes and studentships are offered by the R.I.B.A. each year for competition among architectural students throughout the commonwealth. Open to students who are British subjects is the Rome scholarship in architecture, established in 1913 by the royal commissioners of the exhibition of 1851. (J. C. P.)

United States.—In the early days of the republic, the usual method of entering the architectural profession was, as in Europe, by a period of apprenticeship in an architect's office, supplemented whenever practicable by evening or part-time classes. As early as 1814, however, Thomas Jefferson included architecture in his program of higher education, and in the 1830s Robert Mills established a school of architecture in Washington, D.C. These projects, with several other ventures, did not immediately bear fruit and architecture commonly was a by-product of the technical colleges and schools of engineering. It was not until after passage of the Morrill Land-Grant act (1862), by which allotments of public land were made available in each state for the building of technical institutions, that the first successful professional schools of architecture emerged, the first three being those of the Massachusetts Institute of Technology (1868), Cornell university (1870) and the University of Illinois (1871). By 1898 nine schools were actively working, with a total enrollment of 362 regular students.

At that time too an increasing number of persons sought their professional education at the École des Beaux-Arts and, on returning to the United States, attempted to institute the French atelier system of tuition in their own country. So strong did this movement become that in 1894 a Society of Beaux-Arts Architects was formed in the United States to establish a central school of architecture on the French model. This was never achieved but, reconstituted in 1916 as the Beaux-Arts Institute of Design, the society continued to exercise considerable influence by its program of design competitions open to students throughout the country.

Teachers of architecture trained in the Paris *école* and advocating the same principles as their former French tutors soon were entrenched in the new schools. Thus young students in the United States, like the majority of young Europeans, were taught the arts of design in the classical, Gothic and Renaissance styles.

The revolt against eclecticism and the academies, that became so important a feature of the European scene at the turn of the century, and the example set by such architectural pioneers as Louis Sullivan and Frank Lloyd Wright, had little immediate influence upon U.S. education. But in 1932 an exhibition of modern architecture at the Museum of Modern Art, New York city, drew attention to the work and philosophy of such European progressives as Le Corbusier, Walter Gropius, Ludwig Mies van der Rohe, and, among others, Wright, Raymond Hood, William Lescaze and Richard Neutra. Political and economic instability in continental Europe caused many leaders of the new movement to move westward during the mid-1930s, first to England, then to take up teaching posts in the United States. In 1938 Gropius was invited to Harvard and was joined shortly afterward by his former colleague Marcel Breuer. Laszlo Moholy-Nagy, also of the Bauhaus, went to Chicago and in 1937 founded the "New Bauhaus," which in 1949, as the Institute of Design, merged with the Illinois Institute of Technology; and in 1938 Mies van der Rohe was appointed director of the school of architecture of the same institute.

Throughout this second phase of European influence, however, more varied influences were at work; and against the formal pattern of training can be set Frank Lloyd Wright's Taliesin fellowship and Eliel Saarinen's Cranbrook academy. The rationalist philosophies of the central Europeans were gradually enriched, diversified and largely assimilated by a new generation of architects; and the decade following World War II saw considerable reorientation in the schools. Architects trained in the 1930s began to assume leadership, and curriculums were scrutinized and revised in order to meet more adequately the needs of training for contemporary practice. The American Institute of Architects (A.I.A.), through its board of architectural education and research, played an even more important part in shaping educational policy, and practising architects throughout the country took an increasing interest in educational affairs.

A survey made by the A.I.A. in 1953 (*The Architect at Mid-Century*) showed that 64 schools were then established in the U.S., the majority of which offered a five-year curriculum leading to a degree or degrees (Bachelor of Architecture or Bachelor of Science in Architecture). Professional registration, whereby an architect is given licence to practise on his own account, is normally secured by examination following a period of at least three years in practice after graduation.

Latin America.—*Mexico.*—For many years architectural education in Mexico conformed in general to the pattern set by western Europe, the architect acquiring his training by apprenticeship. Although at the beginning of formal architectural schools Spanish and Italian influences were strong, the methods and principles of the École des Beaux-Arts soon dominated; one of the first courses in architecture introduced by the Mexican National Academy of Fine Arts was not only modeled upon that of the *école* but was largely directed by teachers with experience of the French system. Later, and more especially after World War II, Mexico made immense strides in architecture. The National School of Architecture is housed at the National Autonomous University of Mexico, in the construction of which 75 architects collaborated, providing remarkable evidence of the vitality of the modern movement in Mexico. The excellent five-year courses lead to a degree in architecture. Similar courses are offered at the industrially supported Monterrey Institute of Technology, the program of which is modeled on that of the Massachusetts Institute of Technology. A successful summer school is held each year at Monterrey jointly with the University of Texas (Austin). There are schools of architecture also at the University of Guadalajara and the Technological institute, Guadalajara. (T. Hh.)

South America.—The foundations of architecture and architectural education in South America were laid during the first colonial centuries, when the architecture of the Spanish Jesuit missions established a brilliant precedent especially in religious buildings. Early in the 20th century a new influence came from the great European immigrations; Italy especially contributed both masons and builders. Meanwhile, houses built by French architects or Latin Americans educated in Paris tended to follow the French style. Throughout South America architectural teaching and practice suffered by becoming overly academic. A revival began with the ministry of health and education building in Rio de Janeiro, the work of Le Corbusier, and with his lectures in Rio and the cities of the Río de la Plata (1929).

Argentina illustrates the development of architectural teaching in South America. Until 1810, instruction was offered only in drawing, but the Academy of Fine Arts, founded in that year, offered the rudiments of architecture. By 1878 an architect's degree could be obtained upon completion of the first four years engineering syllabus. In 1901 a group of Paris-trained architects founded the School of Architecture within the faculty of engineering in the University of Buenos Aires; the school became a faculty in 1946.

Except for Paraguay, all South American countries have architectural schools. These have much in common: syllabuses in which scientific and aesthetic courses are well balanced; five- or six-year courses in city planning and social problems; intensive study of reinforced concrete (the basic building material in the continent); and (except in Argentina) limited entry. Some, such as the faculty of architecture in the University of Chile, have building departments in which students gain practical experience by carrying out building programs for the university. The school of architecture at the Catholic University of Valparaiso deserves special mention for its apprenticeship system of education. (Ed. S.)

Japan.—Since 1873 Japanese architectural education has been under European influence. Before that knowledge of building was transmitted from master carpenter to apprentice through direct instruction. At the first national university, Tokyo Imperial, now Tokyo university, the first students of the department of architecture graduated in 1879, and architectural degrees were awarded at Waseda university in 1913 and Kyoto university in 1923. After World War II the education system was reformed. The course was prolonged one year, the four years being divided into two parts, with professional education assigned to the last two years. Within 15 years after the end of the war 20 national universities and 15 private universities had departments of architecture, graduating over 1,000 every year. Departments of architecture are not independent as in other countries, but belong to the schools of engineering. Only 20%–25% of graduates practise design after graduation. In some universities a two-year (master's degree) and a three-year (doctor's degree) course of graduate study is offered. (K. Ta.)

ARCHITECTURAL ENGINEERING. Architecture has been defined as the art and technique of building; architectural engineering is that aspect of architecture most concerned with the technique of building (*see* also Architecture). At times the distinction between art and technique has tended almost to disappear (*e.g.*, the best Gothic architecture), and at other times has been marked to an alarming degree (*e.g.*, the worst 19th-century architecture). This article deals with structural engineering, both its history and principles of design, and environmental control. The article is divided into the following sections:

I. STRUCTURAL ENGINEERING

A. History

Structural engineering is that branch of engineering concerned with creating and, particularly, with designing structures. While originally relating primarily to civil engineering structures such as bridges, buildings, dams and the like, it now embraces all engineering design in which the chief requirement is the attainment of adequate strength by economical means, in keeping with the intended function of the structure. In this sense the structural design of aircraft, ships, pressure vessels (boilers, etc.), tanks, reservoirs and water towers, electrical transmission line towers and antenna masts, and a multitude of other products of technology, also falls within the compass of structural engineering.

As soon as man began to build, whether shelter, temple or bridge, he had to impart to his structure the strength needed to resist the forces of high winds, the weight of snow and other loads, such as that of the structure itself and of those using it. Aside from his personal skill he was helped only by the knowledge and tradition of previous experience. There was no body of scientific knowledge to aid in structural design until roughly the beginning of the 19th century.

1. Prescientific Development.—During the ages when masonry was the universal material for permanent construction, arches, vaults and domes were the only means of bridging sizable spans and of enclosing large spaces. These means illustrate the development which structural practice was able to achieve without the aid of structural science.

True voussoir arches (*see* ARCH AND VAULT) of wedge-shaped stones with radially arranged joints were used by the Egyptians and Ethiopians about 2000 B.C. Though the Greeks did not employ arches in their formal architecture, they must have known about them since Aristotle speaks of the keystones of arches supporting the structure by the "resistance which they oppose to all sides." This acute observation covers the extent of scientific understanding of arch action for about the next 2,000 years, as is evident from the following description of the nature of an arch by Leonardo da Vinci: "A strength developed by two weaknesses, for the arch is composed of two segments of a circle each of which, being weak in itself, tends to fall; but as each opposes this tendency in the other, the two weaknesses combine to form one strength." Such qualitative insight into the nature of arches, however, is of no quantitative use to one who has to decide what shape (circular, parabolic, elliptical, pointed) and what thickness of arch rib will be appropriate to carry the superimposed load of an arch of given span and of given material (brick, granite, marble). Yet during this very interval, roughly from 300 B.C. to A.D. 1500, the greatest development of arched, vaulted and domed construction took place.

The large-scale use of the masonry arch was begun by the Romans, starting from earlier Etruscan developments. The Aqua Appia aqueduct, begun in 312 B.C., was probably the first of the great Roman arched utility structures. During the next 500 years great numbers of arched bridges and aqueducts were built, dozens of which survive today. Spans of 80 ft. and more were not unusual; the bridge constructed in the time of Augustus Caesar at Narni, Italy, had a span given, variously, as between 111 ft. and 142 ft. As to height, the famous Pont du Gard at Nîmes, France, a three-tiered aqueduct and viaduct, rises to 155 ft., while the Puente Trajan across the Tagus river in Spain, with two main arch spans of more than 90 ft. each, reaches a height of more than 130 ft. All of these Roman arches are circular in shape, and most of them are complete half circles. They are made without mortar, the individual voussoirs having been cut with such accuracy as to result in perfect fit. Iron or bronze dowels were used between individual stones.

To enclose large spaces the Romans used not only barrel vaults, which are merely arches of great width, but also domes of circular plan (*see* DOME). The earliest known use of domes, on a small scale for roofs of huts, apparently was in Mesopotamia in the 8th century B.C. The long and discontinuous development found its climax in the Pantheon, completed in Rome under Hadrian in A.D. 125. It is a circular brick dome 142 ft. in diameter that rises to a height of 71 ft. from its springing. For sheer size of space enclosed without interior columns or other supports this structure was not equaled for more than 1,300 years, and not exceeded until the second half of the 19th century.

This revolutionary development, as well as the subsequent use of arches and vaults in the much less daring structures of Romanesque church architecture, was stereotyped in two respects. First, arches were almost invariably circular, which facilitated stonecutting but did not achieve optimum strength. Second, stability was achieved by sheer mass—the heavy piers and abutments of Roman bridges, and the excessively thick, small-windowed, buttressed walls of Romanesque churches and cathedrals. It remained for the Gothic builders to take the most daring step of all, to achieve stability by shape rather than by mass.

By pointing the arches and stretching them upward into a better structural shape, the Gothic builders not only lightened the arches themselves, but also, with tall, steep ribs, made the lateral thrust on the piers and abutments much less than that of the squat, heavy, circular arches. To resist the smaller side thrusts it was no longer necessary to provide large masses and heavy counterforts. Interior piers, through delicate balancing of the side thrusts of the several differently shaped arches supported by each one of them, became tall, taut columns of extreme slenderness. To provide lateral support for the arches rising inward from the exterior walls, massive counterforts could be replaced by light flying buttresses which, by virtue of their shape, were able to carry the arch thrust safely to the foundation without reliance on the stabilizing power of sheer bulk. Walls completely dissolved, and the entire structure became an upward pointed arrangement of interlaced arched ribs springing from columns and buttresses so slender that there was hardly any distinction between them and the arches. Inspired by the unique spiritual idea of the Gothic cathedral, these men went to the very limits of the structural possibilities of masonry (*see* GOTHIC ARCHITECTURE).

No previous experience provided guides for the dimensioning of this type of structure. Such experience was gained only in the construction of the cathedrals themselves and was paid for dearly in repeated collapses and failures. Not only are there actual records of the repeated failures, but legends tell how the devil kept tearing down each night what the workmen had constructed the previous day, and that final completion was due only to the intervention of heaven—testimony to the contemporary belief that such construction was really beyond the compass of human capabilities.

Arched, vaulted and domed construction reached its apex at the transition from the Gothic to the Renaissance in Brunelleschi's dome of the cathedral of Florence. The mean diameter of the octagonal area which it covers is almost exactly the same as that of the Pantheon in Rome, but rather than being circular in cross section, the dome is elongated upward and pointed like a Gothic arch, so that it rises to a height of 105 ft. from its springings. Structurally it is an intricate combination of a double-shelled dome (an innovation followed by all subsequent builders of masonry domes) and an 8-ribbed vault with 16 subsidiary ribs. Built freely into the air without scaffolding, and carrying a heavy masonry lantern over its open top, its shape was so perfectly selected that investigation by modern engineering analysis revealed hardly any structural feature which could have been improved upon with the technical means of masonry construction available at the time.

2. Roots of Scientific Development.—The transformation of structural engineering from a traditional art to a scientifically

based branch of engineering resulted from the following:

1. Systematic investigation began, by test and experiment, of the relevant properties of structural materials and of structural members made of them, particularly strength and resistance to forces of compression, tension, bending, shearing and the like.

2. Methods for calculating the forces caused within the material of a structure by the loads acting on it from without (structural analysis) were developed. Taken in conjunction with the relevant properties of the material used (1, above), these methods furnish the means of predicting quantitatively the reaction of the structure to such loads and forces, the manner in which it will deflect and deform, and the magnitude of stress and strain which will cause it to collapse and fail. (*See* MATERIALS, STRENGTH OF.)

3. The rapid technological, economic and social development that began with the Industrial Revolution in the latter part of the 18th century called for speedy solutions to structural problems which had no precedent and for which the slow trial and error process of the prescientific age was wholly inadequate. For example, in transportation alone, canals and their locks changed from small inland waterways to the vast installations of the Panama canal; railroad trains, rapidly increasing in both size and speed, had to be carried over bridges of ever-increasing span; highway motor transportation made similar demands on bridge engineering; ships became huge ocean liners and cargo boats which required larger harbour installations; and with dirigibles and airplanes came the need for hangars for them. All of these developments called for new types of structures made of new kinds of materials and designed scientifically; *i.e.*, with performance predictable not by precedent but by systematic use of general scientific knowledge.

4. Artificial structural materials were created with properties better adapted to their specific use and much more closely controllable in manufacture than those of the older materials (stone, timber, lime mortar, natural cement). The most important of these newer materials were (in approximate chronological order) cast iron, wrought iron, carbon and alloy steels, portland and special cements and concrete made with such cements, aluminum alloys and other lightweight metals; and there were new ways of using timber, such as plywood.

3. Founding of Structural Science.—The broad development of structural science began only toward the end of the 17th century and did not achieve the status of an effective engineering tool before the first half of the 19th century. It was preceded by two solitary figures, separated from each other by more than 100 years, and from subsequent progress by another half century: Leonardo da Vinci (1452–1519), painter, sculptor, architect, military and civil engineer, physicist, biologist and one of the most remarkably universal men that ever lived; and Galileo Galilei (1564–1642), astronomer, physicist, founder of classical mechanics and probably the first natural scientist in the modern sense.

The main distinction of Leonardo's contribution lies neither in his actual discoveries nor in their influence on subsequent development. In fact, this influence was rather slight, because his observations were haphazardly laid down in mirror-writing and sketches in the hundreds of pages of his notebooks, ranging over the entire area of his limitless interests. It is the method of approach of Leonardo's investigations which marks the turning point from traditional art to scientific structural engineering. His subjects included beams, columns, arches, trusses, wires. Toward all of them he had a dual approach: investigation by experiment, and application of the science of mechanics to structural problems in an attempt at quantitative calculation. In his detailed prescriptions on how to test the strength of beams, columns and wires, he indicated how the relevant variables (such as length, width and area of cross section) should be varied systematically in a series of several tests to obtain answers applicable not only, for instance, to a single tested beam, but to all beams whether actually tested or not. This method remained essentially the basis of systematic experimentation. Likewise, his attempts at determining reactions of (and internal forces in) structural framework by making use of the known simple propositions of statics, such as the law of the levers, represent the first instance of what was to develop into the discipline of structural analysis—application of the laws of physics, and particularly of mechanics, to the numerical calculation of the performance of engineering structures.

Galileo, who seems to have had some knowledge of Leonardo's work, used this same dual approach to arrive at the first quantitative results in structural science. He had a clear understanding of the resistance of structural elements to tension, showing that such resistance depends only on the area of the cross section and on the quality of the material used, of which he gave examples by relating actual test results of the tensile strength of copper. His investigations of the bending of beams, though mistaken in two assumptions relating to the distribution of internal forces, were so basic, precise and comprehensive as to influence all subsequent development. Indeed, so great was his authority that, in spite of the fact that the mistaken parts of his theory of bending had been improved and corrected by Edmé Mariotte in 1680 and by C. A. Coulomb in 1773, his two mistakes were repeated in some English and German textbooks well into the beginning of the 19th century.

4. Structural Analysis.—There developed from these beginnings a vast discipline whose scope can only barely be outlined here. In 1757 the Swiss mathematician Leonhard Euler published his analysis of the strength of columns, the basis of all subsequent development of the theory of buckling of structures. Coulomb in his famous memoir of 1773 (the first scientific structural treatise written by a practising engineer for the practising engineer) provided the correct basis for the analysis of beams, thus culminating the development started by Galileo. He also gave experimental results on the strength of sandstones, obtained on testing machines of his own design; developed a valid theory of earth pressure on retaining walls; formulated the first rational hypothesis of the conditions of the internal forces which cause brittle materials like stone to fracture; and dealt with the stability of arches. In another paper he dealt with the resistance of beams to twisting.

The theory of elasticity, one of the components of all structural analysis, was developed in France by Louis Navier (1785–1836) and his contemporaries Augustin Cauchy and Siméon Poisson. In 1826 Navier's published lectures represented the first systematic text on the strength of materials and on structural analysis based on the entire contemporary body of knowledge. Among many other original contributions, he developed the beginnings of the theory of suspension bridges, a number of which had been built in the preceding decades in England, their design having been based on careful experiments rather than on theory. Another early text of great influence in making scientific information available to designing engineers and architects was W. J. M. Rankine's *Manual of Applied Mechanics*, first published in 1858 and reissued with regular revisions for half a century.

The first practical method of analyzing trusses, a form of structure first developed by Andrea Palladio in the 16th century for supporting roofs and later also extensively used for timber bridges, was published in 1847 by Squire Whipple, U.S. engineer. J. C. Maxwell (Scottish), K. Culmann (Swiss), A. Castigliano (Italian) and H. Müller-Breslau (German), during the period from 1850 to 1910, laid the foundations and developed the basic methods for analyzing the modern types of framed structures for bridges and buildings. These same methods also found immediate application in ship construction (for which Thomas Young [1773–1829] was the first to have indicated a rational design approach) and later in the design of airplanes.

5. Structural Materials.—From the earliest beginnings of building to the time of the Industrial Revolution, timber, stone, brick and mortar made with lime or natural cement had remained the only structural materials. Metals in the form of small bronze or iron ties, clamps or dowels had found only occasional use for assuring more positive connections. The earliest investigators realized that even such rudiments of structural analysis as were available at the time were of no practical use unless supplemented by experimental information on the strength properties of these materials.

Mariotte was probably the first to make systematic tests of the strength in tension and bending of timber, metal and some other materials. He measured not only the forces necessary to fracture

the material, but also the deformations (deflection of beams, stretch of wires) prior to fracture, information which is essential in connection with all structural use. However, the systematic testing of structural materials was initiated by Pieter van Musschenbroek (1692–1761) of Holland, who developed special apparatus, similar in principle to some still in use, for the testing of beams and other structural elements in bending, tension, compression and other forms of stress. His data on various materials and their behaviour were extensively used by contemporary engineers. Late in the 18th and early in the 19th century, Coulomb and Pierre S. Girard in France, and Peter Barlow and Thomas Tredgold in England further advanced experimental techniques and accumulated useful information. In particular, T. Telford designed and built (1819–26) over the Menai strait in Wales a suspension bridge of 580 ft. span by means of wrought-iron chains. To determine the adequate strength of these chains, he established by full-size tests not only their strength, but the forces which would be acting in them once they were installed in the bridge.

Cast Iron.—The first of the new materials to be used structurally was cast iron; its employment for arch bridges was proposed by John Smeaton in 1755. The first such bridge was built in Coalbrookdale, Shropshire, Eng., in 1776 and was followed by many others. From that time, in England and then elsewhere, until well into the 19th century, factory buildings up to seven stories high were made with cast-iron columns and later also with flanged cast-iron beams for supporting the brick floors. Extensive tests by Tredgold, Eaton Hodgkinson and Sir William Fairbairn preceded the successful use of this material.

Wrought Iron.—Brittleness limited the structural usefulness of cast iron, but the tougher and more ductile wrought iron came into structural use after the introduction of the rolling mill by Henry Colt (1784). Rolled I-shaped beams (another example of strength achieved by shape) were first introduced in France by Ferdinand Zorès in 1845 in response to a unique situation compounded of a strike of masons, high prices for timber, fear of fire in combustible construction, and the increasing demand for longer span beams and ceilings.

Steel.—While wrought iron remained relatively expensive and somewhat unpredictable as to its properties, the processes developed by Henry Bessemer, William Kelly, Friedrich and Sir William Siemens and Pierre Martin between 1856 and 1862 provided an ample and cheap supply of steel. Its first large-scale structural use came in the girders of the upper stories of the Home Insurance building in Chicago, 1883. In 1894 the Carnegie-Phipps Co. in Pittsburgh issued the first handbook of rolled structural steel shapes (I beams, angles, channels, plates, etc.), which gave the designer information on available products and their structural properties. This publication became the forerunner of many similar ones in use all over the world.

Cement and Concrete.—Other structural materials include portland cement (patented by J. Aspdin in 1824) and concrete, an artificial stone made of sand, gravel, water and cement. The properties of concrete were somewhat unreliable until Duff Abrams in 1918 developed the principles of so proportioning the four ingredients as to obtain a concrete of predictable and controllable quality. Like any stonelike material, concrete is strong in resisting compression, but offers little resistance to tension and bending. Steel, on the other hand, is most favourably used when subjected to tension. Reinforced concrete, first used in buildings in the 1890s by François Hennebique in France and Frederick Ransome in the U.S., combines the advantageous properties of these two materials by embedding steel rods in the concrete mainly in those locations where tensile stresses would fracture the unreinforced concrete. Combining the durability, fire resistance, moldability and low price of concrete with the toughness and tensile strength of steel, reinforced concrete became one of the mainstays of modern construction.

Aluminum.—Industrial mass production of aluminum was developed by Charles M. Hall in 1886. By alloying it with other elements it can be made about as strong as steel; its chief advantages over steel are its lightness and its corrosion resistance. Its main structural applications have been in airplanes, but by the second half of the 20th century it was finding increasing use in other structures, including bridges and buildings.

6. Contemporary Types of Structures.—These differ from earlier construction chiefly in their clarification of structural function. The conventional heavy bearing walls and brick and timber floors were first replaced in the early English factories by cast-iron columns and floor beams whose only purpose was that of carrying load. In the Chicago school, chiefly the creation of William Le Baron Jenney, early use of iron developed around 1890 into the all iron and steel skeleton of the modern skyscraper, in which all loads are carried by the frame, and the walls are merely curtains serving for insulation and enclosure. Windows could be enlarged until they constituted a large fraction of the wall area. In the 1950s prefabricated light metal panels came to be used increasingly for exterior and interior walls in place of the conventional brick or masonry units. The use of steel framing permitted greater building heights and more flexibility in the use of the interior space.

A similar trend toward functional clarification is also evident from the comparison of modern bridges with those of earlier times (*see* BRIDGES). In addition to bridge building, the long-span roof freely enclosing a large space may serve as a gauge of structural evolution. This development took place chiefly in connection with markets, department stores, exhibition buildings, auditoriums, sports arenas and hangars. The Hungerford Fish market in London was an early (1835) example of free-spanning cast-iron construction of "modern" design. The Crystal palace, London (1851), represented the first all-iron framed building of large size. By way of the Palais de l'Industrie of the 1855 Paris exhibition, whose free span of 142 ft. about equaled that of the Pantheon, this development found its early culmination in the Galérie des Machines of the 1889 Paris exhibition. Its three-hinged, articulated and latticed steel arches had a free span of 377 ft. and represented a triumph of the recently emerged art of steel construction (*q.v.*).

While early long-span roof structures tended to be subdivided into individual, repetitive elements, somewhat as if a number of individual bridges had been put side by side to form the roof support, later types were designed as three-dimensional space structures obtaining their strength from being curved in all directions in the manner of an egg shell. Such reinforced concrete shells and the theory of their design were developed by Eugène Freyssinet in France and Franz Dischinger in Germany in the 1920s. The dome of a market hall in Algeciras, Spain, designed in 1934 by E. Torroja, covers an area larger than the Pantheon and has a thickness as small as 3½ in. at its thinnest. A similarly thin dome over an auditorium in Cambridge, Mass., rests on three points spaced 160 ft. from each other. Instead of a solid shell, such structures are also being made up of a network of light ribs. P. L. Nervi used this type of construction in precast reinforced concrete in imaginative ways in a number of hangars and exposition halls with spans up to 224 ft. The Dome of Discovery in London, built in the mid-1950s, covered an area of 365 ft. diameter (larger than any previous dome) by means of a dome-shaped network of light aluminum ribs.

Airplanes, likewise, represent such space structures in which spars, ribs, stiffeners and the outer metal skin jointly contribute in a delicately balanced manner toward attaining maximum strength with minimum weight ("stressed-skin structures"). The same principles of imparting strength to thin light structures by appropriate shaping are applied in such other structures as stressed-skin prefabricated houses of light timber framing bonded to strength-imparting skins of plywood or other wall sheeting, and lightweight steel structural shapes and floor and wall panels formed, for strength and rigidity, of sheet steel almost as thin as that of which automobile bodies are made.

Space structures of a different kind are the tall masts and antenna towers required for radio communication, particularly television. Consisting of relatively light, latticed masts braced against wind forces from any direction by systems of steel guy cables, they present entirely novel problems of structural theory as well as of erection techniques, and are among the highest structures. The height of several exceeds 1,000 ft.; a mast of 1,572 ft.

in Oklahoma City, Okla., was at the time of erection in 1954 the tallest man-made structure.

In all these examples structural efficiency is achieved by adaptation of shape to reduce and distribute favourably the internal forces acting within the structure to resist the external loads. It is these internal forces of compression, tension, shear and the like which, when permitted to exceed certain limits, cause structural breakdown. In the great majority of structures, material is treated as essentially passive; that is, as merely resisting these active forces. A novel method, that of prestressing, consists in introducing into a structure, in advance of loading, internal forces which are so directed by the designer that they will actively oppose the disruptive internal forces caused by the external loads. Since, as previously indicated, concrete is a material weak in tension, the essentially passive approach of conventional reinforced concrete construction has been to embed strengthening steel rods in those locations in the structure in which the external forces cause internal tension. The more active approach of prestressed concrete construction uses tightened steel cables in the concrete for creating, in advance, compression in those parts of the structure in which subsequent external loads will tend to cause tension. Thus, the structure has been strengthened by introduction of intentional internal forces directed and arranged to resist those caused by the loads. This results in saving of material and, therefore, frequently in a more economical design.

Another significant development in structural science is ultimate strength design. All structural materials are elastic at relatively low stress, but in various degrees all of them become plastic at higher loads and stresses. Formerly almost all structural design was based on preventing elastic failure; that is, on providing a margin of safety against even minute permanent deformations. In the late 1930s engineers began to realize that this rather formalistic criterion of elastic failure is often an inadequate and overconservative measure of the real, usable strength of many types of structures. A more realistic calculation of the actual strength can only be obtained by due consideration of the added resistance which many structures develop while undergoing limited amounts of plastic deformation. Thus the theory of plasticity, while still in its infancy at mid-20th century as compared to that of elasticity, had already provided important methods for the more efficient design of structures. (*See* also Architecture.) (G. Wr.)

B. Design Principles

Contemporary structural engineering is founded on the physical sciences. Through their application the engineer can predict the behaviour of a structure under various conditions. Through a process of analysis, the state of stress and strain in a structure is obtained and compared with values that have been empirically found safe for various materials. If the stress and strain values found by analysis are not greater than the safe values, the structure is satisfactory for the initially assumed loads.

Two important observations must be made regarding the process outlined above. First, engineering analysis is, at best, probable, because it deals with specific phenomena that will only approximate average behaviour. It is assumed that the material will behave according to the idealized average behaviour of that material. In reality, materials usually deviate from this average by amounts that depend on the care employed in their manufacture. Structural steel, used for buildings and bridges, is assumed to have an ultimate tensile strength of 72,000 lb. per square inch (p.s.i.). This means that a bar of this material with a cross section of one square inch should break under a load of 72,000 lb. In reality, a large number of tests would show that while most bars break at the predicted average load an appreciable number fail at larger or smaller loads.

Other probable assumptions used in an analysis are the magnitudes of the applied loads, from which the stress and strain of the structure are predicted. In analyzing the beams supporting the floor of a residential building, it is ordinarily assumed that the weight of the construction (dead load) and the weight of people and furniture associated with normal occupancy (live load) can be entered as an exact number in the analysis. It is clear, however, that this number may be subject to great fluctuations. The live load may be assumed to be 40 lb. per square foot (p.s.f.) distributed uniformly over the entire area of the floor; in reality, the weight of people and furniture varies appreciably from the assumed average.

In order to allow for these deviations from the assumed average, the structure is built to perform satisfactorily at loads higher than the anticipated maximum. This consideration is of vital importance and is usually provided for by law in building ordinances and codes.

The second important observation regarding the analytical process is that it can only be applied to a structure when all of its essential parts are known. The structural materials must have been selected, the type of the structure decided upon and all of the essential dimensions given. On the other hand, final decisions can be made only after the analysis is performed. Therefore, before the analysis proper can be executed, assumptions regarding materials, type of structure and dimensions must be made; later they will be refined by the analysis. That phase of the work in which all essential properties of the structure are conceived, before the analysis, is known as preliminary designing. The initial conception must at least approximate all requirements regarding function, load-carrying ability and economy; frequently preliminary solutions will entirely satisfy the requirements. The activity concerned with conceiving various solutions and selecting the most suitable one is usually called designing. While the analytical phase of structural engineering is based on physical sciences, designing remains essentially an art, for which knowledge of structural analysis, imagination, judgment and experience are prerequisites.

In a narrow sense, the purpose of design and analysis is to produce a structure that will safely support its own weight and all other anticipated superimposed loads; the structure must also be able to resist the effects of the elements (wind, earthquakes, temperature variations, snow and ice, foundation settlement, shrinkage or swelling of materials). Therefore the assumptions regarding loads, stresses, strains and deformations are the basis of the analysis.

Fixed loads (dead loads) consist of the weight of the structure itself, including all of its nonload-carrying parts. The weights of these can be computed, once the dimensions are known, from the specific gravity of the materials used. Movable loads (live loads) consist of humans, vehicles, furniture, etc.; they are estimated as average values in pounds per square foot. Typical live loads are shown in Table I.

Table I.—*Typical Live Loads*

Load	p.s.f.	Load	p.s.f.
Apartment houses		Office buildings	
Private apartments	40	Offices	80
Public stairways	100	Lobbies	100
Assembly halls		Schools	
Fixed seats	60	Classrooms	40
Movable seats	100	Corridors	100
Corridors (upper floors)	100	Stores	125
Snow (roof)		Wind	
(depending on location)	5–40	(depending on location)	5–30

It is customary to provide for the effects of a temperature variation of from about 50° F. to as much as 100° F. (depending on the location). The intensity of earthquakes is estimated on the basis of the past experiences of a location. Their effect is roughly estimated on the basis of the maximum acceleration to which the structure will be subjected during seismic motion. An average value of this acceleration is often assumed to be about one-tenth of the acceleration of gravity (0.1 G.).

Impinging forces (or loads) cause stresses and deformations within the structure. If their magnitude becomes great enough the structure may not be capable of performing its function, and a partial or complete collapse may result. Deformations and stresses must therefore be limited; the magnitude of these limits naturally depends on the material. The stronger material can operate with higher allowable stresses and support heavier loads. Strength characteristics are determined experimentally and average values are computed. Because anticipated maximum loads and

average strength characteristics are merely probable, the allowable stresses and deformations are set at a fraction of those that might impair the structure. The reciprocal of this fraction is termed the factor of safety; it varies, by material and type of load, from a minimum of about 1.5 (for steel) to over 5 (for masonry).

Typical values of allowable stress for structural steel are given in Table II.

Allowable stresses for other materials, such as reinforced concrete, aluminum, wood, masonry, etc., are also established. All of these values are subject to rather complex technical limitations and qualifications depending on the type of material used, the geometric properties of the individual member, minimum and maximum dimensions and other factors. Allowable deflections on beams that support floors are usually limited in terms of the span of the beam itself and are set from 1/360 to 1/180 of the span.

TABLE II.—*Typical Allowable Stresses for Structural Steel*

Stress	p.s.i.	Stress	p.s.i.
Tension	20,000	Shearing . . . . (rivets)	15,000
Compression . . . (columns)	17,000 (max.)	Bearing . . . . (rivets)	32,000–40,000

After the magnitudes of superimposed loads and of other effects have been established, the analysis must show that the structure will remain safe under all possible modes of failure and that the magnitude of stresses and deformations (which are a measure of strain) will be not more than the allowable values. The analysis can conveniently be subdivided according to the following four fundamental modes of failure of a structure:

1. Stability. The most elementary requirement is the stability of the structure. If the entire structure were a rigid body, it should not undergo any significant amount of sliding and rotation under the loads acting upon it. The stability of a structure is ordinarily ensured by its own weight or, if this is not sufficient, by means of guys or anchors. So-called gravity dams and retaining walls oppose the overturning forces of water or earth pressure by their sheer weight. High towers or masts are stabilized by means of guy wires.

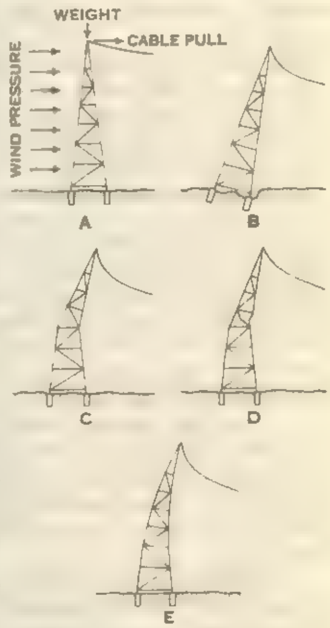
2. Strength. A structure which is stable may still be damaged if forces or loads tear, crush or shear off any part of it. The resistance of the structure against this type of damage is termed its strength. By analytical methods the magnitude of the internal forces and stresses can be determined and compared with allowable stresses. The analysis has to demonstrate that all stresses (tensile, compressive and shear) are not more than the allowable values.

3. Elastic Stability. Compression members, such as columns and struts, are subject to a failure independent of strength in the sense described above. This type of failure is called buckling. It is the tendency of slender members, subjected to compressive forces, to "get away from under the load." Narrow compression flanges of girders exhibit a tendency toward lateral buckling or twisting under transverse loads. All members of a structure must be analyzed for elastic-stability failures.

4. Rigidity. Structures subject to loads are deformed to varying degrees. A beam, for instance, will deflect under a transverse load, and tension members will elongate under axial forces. For satisfactory performance the deformation or distortion of structures must be limited, floors that lack sufficient rigidity will feel uncomfortably springy, or the ceiling plaster may crack.

The process and purpose of structural analysis and design can be further clarified with a greatly simplified example: It is desired to design a tower to support electrical transmission wires. The process of designing consists mainly of deciding on the materials to be used and the shape and dimensions the tower will take. Previous experiences and the comparison of various preliminary designs may lead to a form schematically shown in figure (A). The analysis begins with an estimate of the weight of the structure and the weight of the wires supported by it, together with the weight of snow or ice which may be carried by the wire. These forces act downward and are represented on the sketch by a vertical arrow. In addition, horizontal forces, symbolized by horizontal arrows, result from the pull of the cable and from wind forces, and must be resisted. The materials (which for this purpose would probably be steel) were decided upon during the initial phase of designing, and the allowable stresses are obtainable from building codes. The various fundamental modes of failure are illustrated in figures (B) to (E). Overturning (instability) may result from the action of wind and cable pull, resulting in rigid body rotation around the leeward foundation. Stability in this case will be secured by the combined weight of the tower and its foundation. Stability failure may also result from foundation settlement, which, however, could be classified as an excessive deformation of the subgrade.

One type of strength failure is illustrated in figure (C). As a result of the lateral forces, a windward member may be torn (tension failure). Failure may occur at the connections of the member by the shearing of the rivets. Figure (D) indicates an elastic-stability failure resulting from the buckling of a compression strut on the leeward side. Figure (E) illustrates the effect of insufficient rigidity, resulting in excessive deformations of the tower.



POSSIBLE MODES OF FAILURE RESULTING FROM THE FAULTY DESIGN OF A TOWER

(A) Forces acting upon a transmission tower; (B) failure due to static instability; (C) failure due to tension; (D) failure due to elastic instability (buckling); (E) failure due to excessive deformation

The purpose of the structural analysis is to prevent the failures illustrated from occurring except under loads that are in excess of the expected loads. (P. WR.)

II. ENVIRONMENTAL CONTROL

Man's physical environment consists of those factors which affect his ability to survive and his comfort. The conditions existing at or near the surface of the earth (land surface), chiefly in the tropic and temperate zones, are the most congenial, but other conditions can be created, accidentally or deliberately. Such artificial control over environment becomes especially important as man tends to extend the boundaries of his domain to include areas not on the earth's surface.

The important environmental factors subject to quantitative measurement and engineering control or manipulation are:

1. Atmosphere
   a. Density (pressure)*
   b. Composition*
   c. Temperature*
2. Radiation
   a. High-energy radiation, *e.g.*, cosmic rays, X-rays
   b. Ultraviolet, visible, infrared*
   c. Hertzian waves and longer wave lengths
3. Gravitational force
4. Air-borne vibrations (sound)*
5. Topography*

(The asterisks denote important variables for buildings and other well-controlled areas in general use.)

In the past, the influence of man on the total environment has been of a secondary nature, the most important effects being ecological and topographical. By cutting and/or burning, large wooded areas have been made into open fields. Vast tracts have been transformed into virtual deserts by indiscriminate cultivation by man and catastrophic erosion by natural forces, such as drought, wind and heavy rains. Still other areas, once considered deserts, have been irrigated to the point of supporting luxuriant vegetation.

Man's direct effect on other species has been quite drastic. The spread of agriculture, the tremendous increase in human population since the 18th century, and the growth of urban areas have completely eliminated some indigenous species and vastly reduced others. Birds and larger mammals have been the least successful in competition with man. Insects, on the other hand, have taken advantage of the reduction of natural predators, and at mid-20th century successfully competed with man for the available food supply.

Since the 19th century, engineering projects of increasing scope have changed the landscape to gain control over transportation routes, rivers, waterways and harbours. Other changes have been by-products of industrialization and the search for raw materials; *e.g.*, waste disposal, open-pit mining. And urban areas have spread explosively with shifting and increasing populations.

The influence of man on atmospheric temperature, motion, moisture content and precipitation patterns is highly uncertain. As of mid-20th century, no comprehensive theory of global weather existed which was capable of including all of the suspected influences on the weather pattern. Although there was no agreement on the influence of man's activities on the over-all weather pattern, it did not appear likely that they had had any fundamental effect up to that time. Consideration of the massiveness of the forces known to be the prime movers of weather, such as solar energy and the rotation of the earth, supported this view.

Control over environment requires separation of the space to be controlled from the general environment. The more complete the desired degree of control, the more substantial the separation must be.

1. Thermal Environment.—For engineering purposes, the human body may be considered to be a heat source having a constant temperature and giving off a variable amount of heat. The body transforms the chemical energy of food and oxygen into mechanical work and also into thermal energy (heat) which must be dissipated if the internal temperature of the body is to remain a constant 98.6° F. (37° C.). The amount of heat to be so dissipated varies widely according to size, age, sex and activity. An adult male at rest must dissipate approximately 400 B.Th.U. per hour of metabolic heat, while the same individual engaged in heavy work may generate 2000 B.Th.U. per hour which must also be dissipated. A 10° rise in body temperature almost invariably results in severe damage to the brain, or death.

The processes by which bodily heat is dissipated are:

1. Conduction: heat flow to a solid substance in contact with the body surface.
2. Convection: heat transferred to a fluid moving over the surface of the body, usually air.
3. Evaporation: latent heat added to surface moisture (perspiration) to cause evaporation.
4. Radiation: net loss of heat due to radiation interchange between body surfaces and surrounding surfaces.

To a large extent the body is capable of regulating its own heat loss. In response to the control of the sympathetic nervous system, the surface blood vessels can dilate or contract, thus increasing or decreasing the quantity of blood and, therefore, the heat near the surface. The heat can then be transferred to the surroundings. The other chief means of heat regulation is through the amount of moisture (perspiration) passing through the skin. As this moisture evaporates, heat in quantity equal to the latent heat of vaporization of the water is removed from the body. Of course, the surrounding conditions must allow the heat transfer to take place at the desired rate. Either the surrounding air temperature must be enough lower than body temperature; or the mean radiant temperature of the surroundings must be low enough to allow cooling to take place; or the relative humidity of the surrounding atmosphere must be low enough to permit evaporation at the required rate. Since all of these processes can and do occur simultaneously, the surrounding air and surface temperatures and the relative humidity are closely related to the ability of the body to lose heat.

The manner in which air temperature and relative humidity are related, with certain assumptions of velocity of air motion and neglecting the effect of radiation, is expressed in the so-called psychrometric chart (*see* AIR CONDITIONING). The limits of human tolerance while doing work for extended periods without serious raising of body temperature have been found by experience to be about 88° F. wet-bulb temperature (34° C.). This is equal to nearly 150° F. in completely moisture-free air. This figure can be modified upward or downward depending on the direction of heat transfer by radiation.

The concept of thermal comfort is related to the ease with which the body can adjust its rate of heat loss to its surroundings and degree of activity, and is subjective in nature because of the differing ability of individuals to adapt their bodily processes to the existing conditions.

There have been, however, standards of thermal comfort determined by large numbers of tests involving representative individual responses to varying thermal environments. As might be expected, these standards vary throughout parts of the world. For example, "ideal" winter indoor temperatures (domestic) vary approximately 7° F. between U.S. and British standards, the U.S. "ideal" temperature being about 72° F. and the British 65° F. Differences of this nature can be attributed to traditional differences in clothing, diet and acclimatization.

A considerable degree of control can be extended over the thermal environment in a building or other segregated area by manipulating structural elements and vegetation to make use of natural forces; *i.e.*, sunlight and wind particularly. The building may be oriented so that windows and extensive wall surfaces receive more or less solar radiation or intercept prevailing breezes. Trees and other forms of vegetation may be used to provide shade, either permanently or only during certain seasons, depending on the type of vegetation and the climate. Again, man-made shading devices may be attached to the building surfaces to control heat gain by radiation. Fixed louvers or shades depend upon the changing angle of the sun with the seasons to allow penetration of radiation in the cold months and exclusion of radiation during the hot months. Movable shading devices can provide flexible control in all seasons. Well-employed, these methods may eliminate the need for further controls in mild climates, and in severe climates can greatly reduce the energy consumed for heating and cooling.

All of these processes involve the consumption of energy. Fuels are burned, and the energy released by combustion is transferred either directly to the space (radiation from open fires) or to another medium (air, water, vapour) which is circulated through the space (air only) or through heat-transfer devices such as radiators or panels. Electrical energy is used either to power mechanical devices for raising and lowering temperatures (heat pumps, refrigerators), or directly in resistance or thermoelectric devices.

During the first half of the 20th century several methods were devised for absorbing and storing a large part of the solar energy which falls on buildings. This energy can be used to provide heat for living spaces and hot water, and will eventually be able to supply refrigeration. It was agreed that fossil fuels (coal, oil, gas), being used in ever-increasing quantities without significant replacement, would begin to become scarce and more expensive sometime before the end of the 20th century. Solar energy was expected to become of major importance at that time.

The composition of the atmosphere of inhabited spaces is modified by the inhabitants. During the process of breathing, the oxygen content of inhaled air is reduced by absorption in the lungs, the carbon dioxide content is increased, and considerable water vapour is given off by the moist respiratory tract. In addition the body secretes waste products through the skin which have volatile constituents. Contrary to popular belief (a belief held by most authorities in the 19th century and earlier), the body gives off no substances in concentrations which could be considered poisonous. Any physiological ill effects arising from crowded poorly ventilated spaces can be attributed entirely to increased temperature and humidity. The aesthetic objection to odours could, of course, affect certain physiological responses such as appetite. Thus the need for ventilation (except for spaces considered airtight, which must have the oxygen and carbon dioxide concentrations held within limits) resolves into a problem of temperature and humidity control, with odour control aesthetically

but not physiologically, necessary.

2. Luminous Environment.—Of the entire spectrum of electromagnetic radiation, ranging from cosmic rays (wave length 10^{-10} cm.) to power-transmission wave lengths (wave length 1.6×10^{10} cm. or about 100,000 mi.), the human eye responds only to a narrow band of wave lengths (between 0.38×10^{-4} cm. and 0.76×10^{-4} cm.) called the visible spectrum. Most of the radiant energy reaching the earth's surface from the sun falls into this region. Seeing, therefore, is one of our most important means of gaining information.

Visible radiation passes through the transparent parts of the eye, and the rays are focused by the lens so that they converge on the surface of the retina at the back of the eyeball which is covered with sensitized nerve endings. If sufficient energy is focused on this surface, the brain receives enough signals to construct a clear image. If, however, too much light or badly distributed light is received, then the result is to obscure the image. The eye has a built-in system for controlling the amount of light received. The transparent opening of the pupil can dilate to allow more light to enter under dim conditions or contract to exclude light under bright conditions. The response of the eye to quantities of radiation is actually logarithmic rather than linear; that is, in order to increase the apparent brightness of an object by a factor of 1, the amount of radiant energy coming from that object would have to be multiplied by a factor of 10. The maximum brightness that the eye can tolerate without discomfort would have about 1,000,000,000,000 times the energy of the minimum brightness which could be perceived.

The objective of controlled illumination is to provide the eyes with the optimum amount of radiant energy for the perceiving of images. The amount of radiant energy necessary to accomplish this objective varies greatly according to the task or type of visual information required. The viewing of fine detail or small objects requires more light than locating large objects. Also, the distribution of the light must not obscure or hinder the visual task at hand. Again, the problem of glare is more critical when fine visual tasks are attempted than with cruder objectives.

The most important source of illumination is, of course, the sun. Here the problem is one of limiting the amount of light to tolerable limits and of controlling the distribution of the light to eliminate glare. Because of the high intensity of direct sunshine as a source, the more diffuse reflected and scattered light that comes from the surrounding sky is preferred for most visual tasks. All other sources of illumination have their basis in the conversion of a portion of input energy of one form or another into visible radiation. Historically, man has used luminous flame sources (fire, candles, lamps of various sorts) since prehistoric times. More recently, light sources have used filaments heated by electricity or flame (incandescent lamps, mantles); gases, vapours or solids which give off visible radiation when excited by other non-visible, electrically produced radiation (mercury vapour, neon, fluorescent material); and also electric arcs. Other materials which give off visible radiation under the influence of electric current will probably also become important sources of illumination. In all of these instances the factors that indicate which method is to be used are those of economy (the cost of the energy necessary for the desired level of illumination), availability, convenience and suitability of the light produced for particular applications (wave length of colour distribution of the light produced). All of these factors have had an influence on determining standards of adequate illumination.

These standards have been continually revised upward, as efficiencies and quality have been raised and costs have been lowered. (*See* also LIGHTING; ORIENTATION.)

3. Acoustic Environment.—Vibrations with frequencies ranging between about 16 cycles per second and 20,000 cycles per second, when transmitted to the human ear by air or some other medium, are perceived as sound. The relative amounts of energy contained in these vibrations are interpreted as variations in loudness. An analogy can be made between the response of the ear to loudness and of the eye to brightness, although the physical mechanisms involved are completely different. The ratio of the energy level of received signals at the threshold of perception to that at the beginning of discomfort is about the same in each case; about 1 to 1,000,000,000,000. The speed of transmission of sound, of course, is much slower than for light. Sound travels approximately ⅕ mi. per second while light travels 186,000 mi. per second. Sound also differs from light in requiring a gaseous, fluid or solid medium for its transmission.

Control of the acoustic environment usually requires means of providing conditions in which a maximum amount of information can be transmitted from a source to a listener. Information may be contained in speech, music or any other sound conveying a message. Sounds which interfere with the message are termed noise. Acoustic control, then, means that noise must be reduced to a minimum, and the message-conveying sounds must reach listeners with sufficient energy to be clearly perceived and interpreted.

Noise which has its origin outside the listening space can be controlled by (1) removing the source to a distance; (2) enclosing the noise source in a massive enclosure; (3) isolating the listening space by a massive enclosure, which provides no air spaces or other mediums capable of transmitting vibrations between source and listener.

Noise may occur within the listening space because of excessive reverberation (reverberation time is the length of time it takes the energy level of an audible signal which is being reflected and re-reflected by surrounding surfaces to be reduced by absorption at the surfaces and in air to the point of inaudibility); echoes (*i.e.*, an audible signal which is reflected to a listener a sufficient length of time after his receiving the original signal and with sufficient strength so that it is distinctly recognizable); movement of listeners or equipment. Reverberation can usually be controlled by sufficient amounts of materials which absorb sound energy within the space. Echoes and focusing effects can be eliminated by proper shaping of reflecting surfaces and by proper distribution of absorptive materials. In some very large spaces the unaided signal from the source (voice, instrument, etc.) cannot effectively reach the listeners, so that mechanical or electronic amplification and/or distribution is necessary. (*See* also ACOUSTICS OF BUILDINGS.)

4. Sanitary Control.—An inevitable consequence of human occupancy and activity is the accumulation of waste materials, both organic and inorganic, which require removal and disposal. Systems of organic waste removal have gained wide usage since their development in the latter part of the 18th century. Most of the systems presently used in urban areas require large quantities of water both for transportation of wastes and in the treatment of these wastes.

During the 19th century the role of vermin and microorganisms in the cause and spread of disease began to be understood, and the control of filth and other conditions attractive to these forms of life became important for reasons other than aesthetic.

Hospitals, food-processing plants and many other types of spaces have adopted high standards of sanitation; they require construction methods and materials which allow thorough and frequent cleaning, often by mechanized means. This same requirement of efficient waste removal and ease of maintenance has become applicable to dwelling units as well as to the more specialized buildings and areas. (*See* also PLUMBING.)

5. Urban Environment.—Another aspect of human environment—and in some respects the most important factor of all—is the nature and character of the urban region: the visual, spatial, atmospheric and psychological environment created by the complex interaction of the sum of the economic, transportation and social patterns of all the inhabitants. Although created by man, this aspect of environment has only rarely and to a limited extent been controlled by him in a completely rational way.

Engineering control has been extended over certain specific problems arising out of this complex of forces, but by mid-20th century no comprehensive theory had been developed which could take into account all the factors involved and predict what effect changes in one area would have on all the others. As certain conditions have become so important as to be considered crucial, they have also become subject to one form of control or another. Air and water pollution, waste removal, provision of adequate light

and air between buildings, traffic circulation and transportation control, and location of types of activity within the urban framework are all examples of factors which have come under some form of control.

Recognition of a need for, as well as development of, a technique of control has had to precede its application.

It is to be expected that as knowledge in the various fields dealing with urban environmental problems is extended, the techniques of engineering control and the governmental techniques of their application will be developed. (*See* also CITY PLANNING.)

6. Summary and Conclusions.—Well-controlled environment became possible only after the development of the theory, equipment and available energy resources for controlling the various factors involved. At the end of the 19th century the cost of the equipment necessary to provide amenities in a typical large building for general occupancy was about 10% to 15% of the cost of the building. By mid-20th century the cost of this equipment in large urban structures had risen to more than 40% of the cost of the building. The co-ordination of the various services has become a major part of the design of contemporary buildings. The increasing cost of providing and operating these services has been due partly to changed aesthetic criteria (*e.g.*, the desire for large exterior glass areas); partly to new materials and building techniques, usually thinner and lighter than traditional materials; and partly to higher standards.

Considerable thought has been given to the construction of buildings that reflect the growing importance of controlled interior conditions. Architectural features that aid the mechanical devices (*e.g.*, shading devices on building façades exposed to the sun, efficient insulating methods for thermally controlled buildings) have become a legitimate form of aesthetic expression. With continuing advances in building technology, more frequent inclusion of services within the structural fabric of buildings, rather than as a later application, is to be expected. *See* CITY PLANNING; HOUSE DESIGN; INDUSTRIAL ARCHITECTURE; *see* also Index references under "Architectural Engineering" in the Index volume.

ARCHITECTURAL RENDERING is a branch of pictorial art and of architectural design whose special aim is to show, before buildings have been built, how they will look after they have been built. Modern renderings fall into two main categories: the quick perspective "design-study," by which an architect records or develops his initial concept of a proposed building; and the carefully made "presentation rendering," which presents a final design and is made for exhibition and publication.

The Perspective Design-Study.—When an architectural concept first forms in the designer's mind it is, necessarily, of a nebulous character. With the effort of putting it down on paper it emerges and crystallizes. This quick rendition of an idea may be no more than a thumbnail sketch, but if ably drawn the chief features of a design can be rendered clear. The inception of many a famous building can be seen in an apparently insignificant sketch, perhaps drawn during a conference on the back of an envelope.

Not all architects who design well can draw well. Of two eminent designers, Inigo Jones (1573–1652) and Sir Christopher Wren (1632–1723), the former was an outstanding draftsman, the latter was not. There have also been architects who drew beautifully yet designed badly; and when buildings are mechanistic, repetitive or standardized in character, their planners may not draw at all since no artistic problem is involved. But that there is a close relationship, in architecture, between drawing and designing has long been recognized. The link is a talent for visualization, and most architects make many sketches as an aid in developing their designs. When an architect is so engaged, it is as though he were revolving a building in his mind and seeing it from every possible angle.

Such sketches, having no pretensions as pictorial art, are seldom exhibited and are largely unknown to the public; however, their value to the art of architecture is well known within the profession. They are of particular value when a number of architects are associated on a board of design. When the United Nations headquarters in New York city was in the preliminary design stage, there was a board of design consultants made up of architects from many nations, speaking many languages. One language they spoke in common: the quick perspective study. In some of the discussions, the only sound was from pencils scratching on paper. In this project, as in many others, the gradual emergence of the final design can be traced in the progressive studies drawn by the architects involved. The term *parti* is sometimes used for a sketch of the basic scheme or main concept of an architectural design, particularly in plan.

The Presentation Rendering.—When an architect has been retained, it is desirable for him to show his client, as soon as possible, how the proposed building will look. This is something that the blueprints—the plans and elevations—do not readily reveal. Blueprints are geometrical diagrams serving as instructions to contractors; they do not pretend to show how structural forms appear to the human eye. Nor can the appearance of a proposed building be fully described in words. Therefore the architect usually prepares a picture, based on the final plans, which is a preview of the building.

If it is a modest affair and but one client is involved, the needs can usually be met by a pencil or water-colour sketch made simply and even quickly. However, it must be made accurately. A facile renderer can invest a dull design with a seductive charm, and exaggerations when stated in perspective drawings are not readily detected.

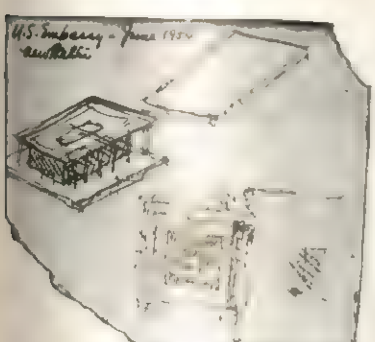
These considerations become even more pressing when the project is of considerable magnitude, such as a large shopping, technical or cultural centre, or a city redevelopment. The client may be a government agency, a board of directors or a large group of investors. Extensive financing may be necessary before actual construction can begin; public relations are often a major consideration. In such cases, the project is usually illustrated from many angles and in considerable detail. The presentation renderings become features in the promotion, and are assumed to have documentary value. They are so prepared as to stand the scrutiny not only of artists and architects but of engineers, realtors, officials, investors and such other interests as may be involved. The purpose of such renderings is not so much to help get buildings designed as to help get the designs understood by all concerned, and thereby to help get buildings built.

Whether the project is simple or complex, the essence of a good rendering is its reliability. This points up the problem (to practitioners, the attraction) of this art. For to portray a proposed building is to portray something that does not exist: rendering is an exercise in imagination. But if the picture is to be other than an architectural fantasy or better than an architectural fake the imagination must be fully controlled by a realization of the structural facts involved. It is a matter of equating artistic reach to architectural grasp.

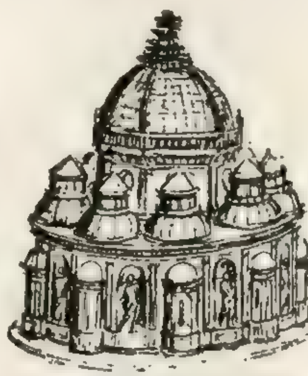
Design for a chapel by Bramante (1444–1514), Italian

Clock tower by Villard de Honnecourt (active about 1230), French

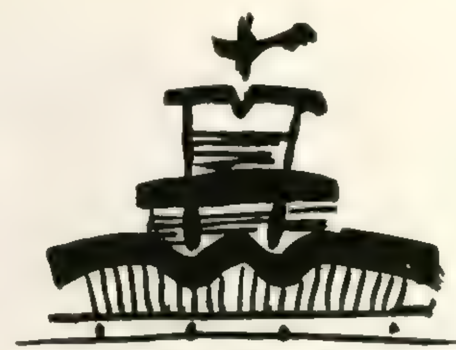
Study for the Masieri memorial, Venice, Italy, by Frank Lloyd Wright (1869–1959), U.S.



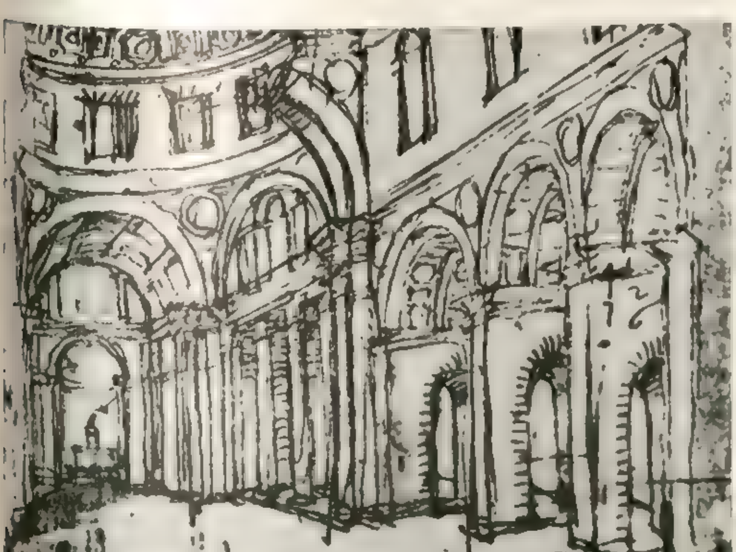
Initial sketch for the U.S. embassy, New Delhi, India, by Edward D. Stone (1902–), U.S.



Design-study by Leonardo da Vinci (1452–1519), Italian



Early study, Opera house, for Lincoln Center, New York city, by Wallace K. Harrison (1895–), U.S.



Study for St. Peter's, Rome, by Baldassare T. Peruzzi (1481–1536), Italian

Early study for Shell headquarters building, London, by Sir Howard Robertson (1888–1963), English

VARIOUS TYPES OF RENDERING

To show how a proposed structure will really look involves a close study of how existing structures really look. People see buildings in different ways depending upon personal interests and limitations: a manufacturer of terra cotta may see, in a building, mainly the terra cotta; a realtor may count every window in a skyscraper. But there are elementary aspects of buildings which almost everyone sees, and these become the more serious concerns of rendering. For example, no one has ever seen an existing building in plan, section or elevation; the eye is so constituted that all objects are seen in perspective. Thus, the renderer's familiarity with the science of perspective draftsmanship is taken for granted (*See* PERSPECTIVE). However, to be lifelike a rendering must be more than a line drawing correctly laid out according to the rules of that science; to stop there achieves only the drafting-room realism that so often fails as art and conveys no lively sense of reality.

In reality, a building does not appear to be an assemblage of lines; it is made up of definite structural forms possessing distinct edges. But an edge is not a drawn line, and the forms are not abstract. The impression of solidity, gained from existing buildings, is essential to any convincing portrayal of proposed buildings, even though a building contains far more space than mass, and some modern buildings are phenomenal in their effect of airy spaciousness. The task, in short, is to portray the solid structural members surrounded by abundant space.

In looking at an existing building one senses it to be standing firmly on its foundation. This is true not only of a massive structure visibly resting on a massive foundation (*e.g.*, the Colosseum at Rome), but also of cantilevered buildings (*e.g.*, Frank Lloyd Wright's "Falling Water," a residence at Bear Run, Pa.) and of light, thin-shell constructions resting on only three point-supports (*e.g.*, Eero Saarinen's auditorium at Massachusetts Institute of Technology). One never sees a building apart from its surroundings, whether these be the natural surroundings of a country site or, in cities, the adjoining buildings and all the activity of street traffic. Buildings are always seen to have colour and textures, and these under the play of light, shade and shadow. And no one has ever seen a building in a vacuum; buildings stand in the atmosphere.

All these aspects of existing buildings have been explored over the centuries by artists as varied as Dürer of the 16th century, Rembrandt of the 17th, Canaletto of the 18th, Thomas Girtin of the 19th and Edward Hopper of the 20th. Such artists have been engaged in interpreting, rather than merely copying, natural appearances. Their interpretations have been highly personal. Their achievements, prompted by aspects of existing buildings, have a bearing on architectural rendering, for the same aspects are to be explored and interpreted in portraying buildings that do not yet exist. A long line of architects and artists has conceived architectural rendering to be a creative art.

History.—*Greece and Rome.*—A classic reference to rendering was supplied by Vitruvius, Roman architect-engineer of the 1st century B.C., who in listing an architect's qualifications wrote, two millenniums ago, "He must have a knowledge of drawing so that he can readily make sketches to show the appearance of the work which he proposes." (*Vitruvius: The Ten Books of Architecture*, trans. by M. H. Morgan, book i, ch. 1, p. 6, Harvard University Press, Cambridge, Mass., 1914.) Vitruvius referred to even earlier writings by Democritus and Anaxagoras, dealing with the same subject. Both gave brief but workable descriptions of perspective.

Actual examples of the ancient use of perspective were preserved in the murals of Pompeii. It appears unlikely that buildings so carefully designed as the baths of Caracalla or the Parthenon could have been constructed without some graphic directives drawn in advance. However, since any such drawings have disappeared it remains only a likely speculation that the Greek architect Ictinus could draw as well as build.

Medieval Europe.—From the middle ages some architectural sketches in perspective do remain; *e.g.*, the famous sketchbook of Villard de Honnecourt, master mason of the 13th century. But architectural rendering as we know it today began in the Renaissance. Collected in many museums and reproduced in many books, there is a wealth of material, both design-studies and presentation renderings by such artist-architects as Brunelleschi, Alberti, Peruzzi, Bramante, the Sangallos, Leonardo and Michelangelo.

Fine Italian renderings were later made by Domenico Fontana, Mauro Tesi and the Bibienas. The etchings of Piranesi (1720–78), while unconcerned with specific building projects, were renditions of a vast architectural imagination.

France.—In France, Jean Lepautre (1618–82) and Daniel Marot (1661–1752) were outstanding as both architects and renderers. The École des Beaux-Arts for many generations led in the perfecting of a type of rendering which involved the addition to carefully drawn plans and elevations of washes in monotone or colour, so applied as to elucidate and enhance the presentation.

England.—In England, the great draftsman Inigo Jones influenced the pictorial work of many architects of the 17th and 18th centuries. Sir John Soane was outstanding in the later 18th century, Charles Robert Cockerell and David Roberts in the early 19th. Thomas Girtin influenced British rendering by his appreciative handling of the environment of buildings including atmospheric conditions. Alfred Waterhouse, architect, was also an able artist of the 19th century. Sir Edwin Lutyens (1869–1944) left an impressive record of the development of an architect's designs from thumbnail sketch through presentation renderings to finished working drawings.

The library of the Royal Institute of British Architects, London, contains about 30,000 original water colours and drawings which amply illustrate the development of rendering in England over four centuries.

The United States.—In the United States, sketches by Thomas Jefferson, as well as early drawings by B. H. Latrobe and William Thornton dealing with designs of the Capitol at Washington, were preserved. A. J. Davis (1803–92) was perhaps the first American architect to gain fame as a renderer, or "architectural composer," as he called himself. Among other architects who could draw or paint as well as design were James Renwick and Richard M. Upjohn of the 19th century; also (their careers extending into the 20th century) Stanford White, Cass Gilbert and his head designer Thomas R. Johnson, H. Van Buren Magonigle, Bertram Grosvenor Goodhue, Charles Z. Klauder, Charles D. Maginnis, Paul Cret, Eric Mendelsohn and Eliel Saarinen. Artists having a love for architecture included Burch Burdette Long, John Taylor Arms and Jules Guerin.

Collections of original renderings by these and other American architects and artists are in many architectural libraries, *e.g.*, Avery (Columbia university), Burnham (Art Institute of Chicago) and the libraries of Massachusetts Institute of Technology, Yale and Harvard.

BIBLIOGRAPHY.—For contemporary techniques and renderers, *see* Sherley W. Morgan, *Architectural Drawing* (1950), which supplies a comprehensive bibliography; also W. W. Atkin, R. Corbelletti and V. R. Fiore, *Pencil Techniques in Modern Design* (1953). Sir Reginald Blomfield, *Architectural Drawing and Draughtsmen* (1912) remains the authoritative treatise on the history of rendering. (H. Fe.)

ARCHITECTURE (ARTICLES ON). The article ARCHITECTURE reviews the major fields of specialization, the techniques associated with the use of various materials and methods, and the various ways of manipulating space to house social institutions in attractive, durable and serviceable ways.

The major historical periods of architecture, the social forces in which they were rooted and the types of design that characterized them are discussed in a series of articles that includes (in approximately chronological order): EGYPTIAN ARCHITECTURE; PRE-HELLENIC ARCHITECTURE; GREEK ARCHITECTURE; ROMAN ARCHITECTURE; BYZANTINE ARCHITECTURE; EARLY CHRISTIAN ARCHITECTURE; ROMANESQUE ARCHITECTURE; GOTHIC ARCHITECTURE; RENAISSANCE ARCHITECTURE; BAROQUE AND POST-BAROQUE ARCHITECTURE; and MODERN ARCHITECTURE. Subdivisions of these periods in which locally distinctive versions were developed are represented by individual articles. For example, GOTHIC ARCHITECTURE is supplemented by three articles describ-

ing historic phases of its development in England: EARLY ENGLISH PERIOD, DECORATED PERIOD and PERPENDICULAR PERIOD; and phases of the Gothic style in France are presented in RAYONNANT STYLE and FLAMBOYANT STYLE. Similarly, RENAISSANCE ARCHITECTURE is supplemented by three articles describing its variations in England: TUDOR PERIOD, ELIZABETHAN STYLE and JACOBEAN STYLE.

Separate articles are devoted also to the historical development of distinctive national architectures, such as CHINESE ARCHITECTURE; INDIAN ARCHITECTURE; JAPANESE ARCHITECTURE; and RUSSIAN ARCHITECTURE. Additional articles on architectural styles include IBERO-AMERICAN ARCHITECTURE and ISLAMIC ARCHITECTURE.

The practical problems involved in the building of a residence today are treated in HOUSE DESIGN; the planning of a building with reference to sun, prevailing winds and similar factors is discussed in ORIENTATION.

Domestic architecture in various regions and eras, and the influences that have created modern trends are discussed in RESIDENTIAL ARCHITECTURE. Articles on other specialized phases include EDUCATIONAL ARCHITECTURE; GOVERNMENTAL ARCHITECTURE; INDUSTRIAL ARCHITECTURE; LIBRARY; MONUMENTS AND MEMORIALS; MUSEUM ARCHITECTURE; PARK AND PLAYGROUND; and RELIGIOUS ARCHITECTURE.

Articles dealing in detail with specific types of building include APARTMENT HOUSE; BASILICA; BATH; CASTLE; CATHEDRAL: *Architecture;* CHÂTEAU; CHURCH: *The Building;* FARM BUILDINGS; HALL; MANOR HOUSE; MINARET; PYRAMID; TEMPLE ARCHITECTURE; THEATRES (STRUCTURES); TOMB; and TOWER.

ARCHITECTURAL EDUCATION describes the general principles involved in directing the energies of talented students into productive channels, and discusses some of the leading architectural schools of the contemporary world.

One of the methods of interpreting architecture to the layman is the visualization of a building in drawings or paintings in which the primary emphasis is placed on their architectural design. These presentations, which are sometimes used by architects for their own guidance during experimental stages, are discussed and illustrated in ARCHITECTURAL RENDERING.

Insights into the visual interpretation of architecture are given in PERSPECTIVE.

The relationship of architecture to other arts and crafts in various cultures and eras, and the influence of shifting standards of taste are discussed in ART and FINE ARTS.

Articles dealing with the economic background of architecture include BUILDING INDUSTRY, which discusses the architect's relationship to the client, the contractor and community agencies; CITY PLANNING; and ZONING.

ARCHITECTURAL ENGINEERING discusses the principles of structural engineering and design, and the problems of environmental control.

The major orders of classical architecture, in each of which a distinctive style of column or pilaster represents a theme with characteristic variations, are described in ORDER, which will be found a helpful supplement to GREEK ARCHITECTURE and ROMAN ARCHITECTURE and to articles on specific buildings of classical Greece and Rome. Other articles related to this subject include BASE; CAPITAL; COLUMN; ENTASIS; and MOLDING.

Many articles are devoted to architectural forms, materials and processes, such as: ARCH AND VAULT; BRICKWORK; DOME; FOUNTAIN; ORNAMENT, ARCHITECTURAL; ROOF; SHOP FRONT DESIGN; SPIRE; STAIR; TRACERY; WINDOW; etc.

For significant insights into the relationship between architecture and the society it exemplifies, the reader should consult the biographical articles on leading architects of various countries and eras.

In many cases, the articles dealing with periods of architecture and regional styles have parallel articles in the field of art—for example, INDIAN ARCHITECTURE is supplemented by INDIAN ART; etc.

Individual buildings of historic or artistic importance are discussed in the general articles listed above, in architectural subdivisions of articles on nations and cities and in such special articles as ALHAMBRA, THE; ERECHTHEUM; PARTHENON; TAJ MAHAL; etc. Reference to the Index will guide the reader to this information and to illustrative plates.

ARCHITECTURE. Architecture is the art and the technique of building, employed to fulfill the practical and expressive requirements of civilized people. Almost every settled society that possesses the techniques for building produces architecture. It is necessary in all but the simplest cultures; without it, man is confined to a primitive struggle with the elements; with it he has not only a defense against the natural environment but also the benefits of a human environment, a prerequisite for and a symbol of the development of civilized institutions.

The characteristics that distinguish a work of architecture from other man-made structures are: (1) Its suitability to use by human beings in general and its adaptability to particular human activities. (2) The stability and permanence of its construction. (3) Its communication of experience and ideas through form.

All these conditions must be met in architecture. The second is a constant, while the first and third vary in relative importance according to the social function of buildings. If the function is chiefly utilitarian, as in a factory, communication is of less importance; if it is chiefly expressive, as in a monumental tomb, utility is a minor concern. In buildings such as churches and city halls, utility and communication may be of equal importance.

In three sections, entitled *Use, Techniques* and *Expression,* this article discusses the means by which these three conditions are fulfilled. They appear under the following headings:

I. USE

The types of architecture are established not by architects but by society, according to the needs of its different institutions. Society sets the goals and assigns to the architect the job of finding the means of achieving them. This section is concerned with types, the role of society in determining the kinds of architecture, and with planning, the role of the architect in adapting designs to particular uses and to the general physical needs of human beings.

A. TYPES

Architecture is created only to fulfill the specifications of an

individual or group. Economic law prevents architects from emulating their fellow artists in producing works for which the demand is nonexistent or only potential. So the types of architecture depend upon social formations and may be classified according to the role of the patron in the community. The types that will be discussed here—domestic, religious, governmental, recreational, welfare and educational, commercial and industrial —represent the simplest possible classification; a scientific typology of architecture would require a more detailed analysis.

1. Domestic Architecture.—Domestic architecture is produced for the social unit: the individual, family or clan and their dependents, human and animal. It provides shelter and security for the basic physical functions of life and at times also for commercial, industrial or agricultural activities that involve the family unit rather than the community. The basic requirements of domestic architecture are simple: a place to sleep, prepare food, eat and perhaps to work; a place that has some light and is protected from the weather and other natural inconveniences. A single room with sturdy walls and roof, a door, a window and a hearth are the necessities; all else is luxury.

The "Vernacular."—In much of the world today, even where institutions have been in a continuous process of change, dwelling types of ancient or prehistoric origin are in use, and in the industrialized United States barns are being built according to a design employed in Europe in the first millennium B.C. The forces that produce a dynamic evolution of architectural style in communal building are usually inactive in the home and farm. The life of the average person may be unaltered by the most fundamental changes in his institutions. He can be successively a slave, the subject of a monarchy and a voting citizen, without having the means or the desire to change his customs, techniques or surroundings. Economic pressure is the major source of his conservatism; lacking the resources of the group, the average individual is forced to restrict his demands to a level far below that which the technology of his time is capable of maintaining. Frequently he builds new structures with old techniques because experiment and innovation are more costly than repetition. But in wealthy cultures economy permits and customs encourage architecture to provide conveniences such as sanitation, lighting and heating, as well as separate areas for distinct functions, and these may come to be regarded as necessities. The same causes tend to replace the conservatism of the home with the aspirations of institutional architecture and to emphasize the expressive as well as the utilitarian function.

"Power" Architecture.—As wealth and expressive functions increase, a special type of domestic building can be distinguished that may be called power architecture. In almost every civilization the pattern of society gives to a few of its members the power to utilize the resources of the community in the construction of their homes, palaces, villas, gardens and places of recreation. These few, whose advantages usually arise from economic, religious or class distinctions, are able to enjoy an infinite variety of domestic activities connected with the mores of their position. These can include even communal functions: the palace of the Flavian emperors in Rome incorporated the activities of the state and the judicial system; the palace of Versailles, a whole city in itself, provided the necessities and luxuries of life for several thousand persons of all classes and was the centre of government for an empire. Power architecture may have a complex expressive function, too, since the symbolizing of power by elegance or display is a responsibility or a necessity (and often a fault) of the powerful. Since this function usually is sought not so much to delight the patron as to demonstrate his social position to others, power architecture becomes communal as well as domestic. In democracies such as ancient Greece and in the western world today, the show of power in private architecture may be reserved, but it is still distinguishable. (*See* also HOUSING.)

Group Housing.—A third type of domestic architecture accommodates the group rather than the unit and is therefore public as well as private. It is familiar to us through the widespread development of mass housing in the modern world, in which individuals or families find living space either in multiple dwellings or in single units produced in quantity. Group housing is produced by many kinds of cultures: by communal states to equalize living standards, by tyrants to assure a docile labour force and by feudal or caste systems to bring together members of a class. The apartment house was developed independently by the imperial Romans to suit urban conditions and by the American Indians to suit agricultural conditions. Group architecture may be power architecture as well, particularly when land values are too high to permit even the wealthy to build privately, as in the 17th-century Place des Vosges in Paris, where aristocratic mansions were designed uniformly around a square, or in the 18th-century flats in English towns and spas. Although most domestic architecture of today employs the style and techniques of the past, the exceptions are more numerous and more important for the development of architecture than ever before. This is because the distribution of wealth and power is widespread in parts of the world where architecture is vital, and because the modern state has assumed responsibility for a large amount of high-quality housing at low cost.

2. Religious Architecture.—The history of architecture is concerned more with religious buildings than with any other type because in most past cultures the universal and exalted appeal of religion made the church or temple the most expressive, the most permanent and the most influential building in any community. (*See* also RELIGIOUS ARCHITECTURE.)

The typology of religious architecture is complex, because no basic requirements such as those that characterize domestic architecture are common to all religions, and because the functions of any one religion involve many different kinds of activity, all of which change with the evolution of cultural patterns.

The temple or church serves as a place of worship and a shelter for the images, relics and holy areas of the cult. In the older religions the temple was not always designed for communal use. In Egypt and ancient Hinduism it was considered the residence of the deity, and entrance into the sanctum was prohibited or reserved for priests; in Greece it contained an accessible cult image, but services were held outside the main façade; and in the ancient near east and in Mayan and Aztec architecture, where the temple was erected at the summit of pyramidal mounds, only privileged members of the community were allowed to approach. Few existing religions are so exclusive. Beliefs as dissimilar as Christianity, Buddhism, Judaism and Islam are based on communal participation in rites held inside the temple or church. The buildings have even evolved into similar plans, because of a common requirement that the maximum number of worshippers be able to face the focal point of the service (the mosque's "point" is the Mecca wall). Consequently, the Moslems were able to adopt the Byzantine church tradition, modern synagogues are often scarcely distinguishable from churches, and early Protestantism absorbed Catholic architecture with only minor revisions (elimination of subsidiary chapels and altars, repositories of relics and some symbolic decoration).

Shelter is not always required for worship. Primitive rites are often practised outdoors with some monument as a focus, while the altar of Pergamum and the Ara Pacis Augustae in Rome are evidences of the open-air observances of the classical world. The atrium (forecourt) of early Christian architecture and the cloister were isolated areas for meditation and prayer.

The complex programs of later religions made the place of worship the focus for varied activities demanding architectural solutions; for example, the baptistery, bell towers and chapter houses of Christian architecture, the minarets around the mosque, and the holy gates of Buddhism. Most modern sects demand space for religious education adjoining the community church or temple. Catholicism and the religions of Asia have produced monasteries, convents and abbeys—connected to places of worship—which accommodate the organized practice of religion, adding domestic and often industrial, agricultural and scholarly functions to the religious.

Shrines and memoria consecrate a holy place for its miraculous character or for its association with the life of the founder, gods or saints of a cult. Since the importance of such structures is usually proportionate to the antiquity of their tradition and asso-

ciations with cult origins, they have had little importance in later architectural history. The major commemorative buildings of Christianity are those connected with the life of Christ (Church of the Nativity in Bethlehem) and the apostles or early church fathers (St. Peter's in Rome) or with the medieval cult of relics (Santiago de Compostela in Spain). No single formal design characterizes this type, but the theme of the domed or central-plan structure (round, square, polygon, Greek cross, etc.) connects the memoria of Asia (the Indian stupa, Chinese pagoda), pagan antiquity (the Pantheon in Rome) and Christianity (the Holy Sepulchre in Jerusalem). The significance of the form is discussed below under *Content*. (*See* also MONUMENTS AND MEMORIALS.)

Funerary art, which expresses man's relationship to the afterlife, is not always architectural, since it may be purely symbolic and therefore suitable to sculptural treatment, as in the classic Greek, medieval and modern tomb. Funerary architecture is produced by societies whose belief in the afterlife is materialistic and by individuals who want to perpetuate and symbolize their temporal power. Monumental tombs have been produced in ancient Egypt (pyramids), Hellenistic Greece (tomb of Mausolus, Halicarnassus, source of the word mausoleum), Rome (tomb of Hadrian), Renaissance Europe (Michelangelo's Medici chapel, Florence) and in the near and far east (Taj Mahal). Modern tomb design has lost vitality, though it remains as elaborate (monument to Victor Emmanuel, Rome) or as meaningful in terms of power (Lenin tomb, Moscow) as before. The exceptional examples are partly sculptural in character (Louis Sullivan's Wainwright tomb, St. Louis, Mo.; Walter Gropius' war memorial, Weimar, Ger.; and the memorial by L. B. di Belgiojoso, E. Rogers and E. Peressutti in a Milan, Italy, cemetery).

Since the 18th century much of religious architecture has lost individuality and importance through the weakening of liturgical traditions. But today, as in the past, outstanding architects have met new demands of use and expression with superior solutions. (*See* TOMB.)

3. Governmental Architecture.—The basic functions of government, to an even greater extent than those of religion, are similar in all societies: administration, legislation and the dispensing of justice. But the architectural needs differ according to the nature of the relationship between the governing and the governed. Where governmental functions are centralized in the hands of a single individual, they are simple and may be exercised in the ruler's residence; where the functions are shared by many, and established as specialized activities, they become complex and demand distinct structures. There are, however, no basic formal solutions for governmental architecture, since the practical needs of government may be met in any sheltered area that has convenient space for deliberation and administration. A distinct type is created rather by expressive functions arising from the ideology of the different systems of political organization (monarchy, theocracy, democracy, etc.) and from the traditions of the various offices of government (law courts, assembly houses, city halls, etc.). Governments that exercise power by force rather than by consent tend to employ the expressive functions of architecture to emphasize their power; they tend to produce buildings of a monumentality disproportionate to their service to the community. Those in which the ruler is given divine attributes bring religious symbolism into architecture. Democratic governments have the responsibility of expressing in their architecture the aims of the community itself, a difficult task in the modern world, when the community may be neither small enough to express itself easily nor homogeneous enough to agree on how to do so.

The simple democratic processes of the Greek city-states and the medieval free towns produced governmental architecture on a domestic scale, while the Roman empire and later monarchies seldom made important distinctions between the place and the seat of state functions. The widespread growth of representative government and the increase in the size and functions of the state in the 19th century created a great variety of buildings, some for entirely new uses. First, capitols, courthouses, parliament buildings, printing offices and mints; and later, post offices, embassies, archives, secretariats and even laboratories, when the work, the increased personnel and the complexity of mechanical aids demanded specialized architectural solutions. Bureaucracy, for better or for worse, has made governmental architecture more important than at any time in history.

In the first rapid expansion from about 1780 to 1840, neoclassic architects found impressive solutions to the new problems, but afterward governmental architecture lapsed into a century of conservatism, following at a safe distance behind private building. After World War II, governmental architecture showed new vitality. Outstanding are Le Corbusier's work at Chandigarh, India, the United Nations Educational, Scientific and Cultural organization headquarters in Paris, and the world-wide program of the U.S. department of state. (*See* GOVERNMENTAL ARCHITECTURE.)

Military building is closer to this type than to others, but its expressive function is so much subordinated to the practical that it is usually regarded as a class of engineering.

4. Recreational Architecture.—Few recreations require architecture until they become institutionalized and must provide for both active and passive participation (athletic events, dramatic and musical performances) or for communal participation in essentially private luxuries (baths, museums and libraries). Throughout history recreational architecture has been the most consistent in form of any type. Diversions may change, but, as in domestic architecture, the physical make-up of the human being provides consistency. If his participation is passive he must be able to hear and to see in comfort; if active, he must be given spaces suited to the chosen activity. In most cultures, recreational institutions have their origins in religious rites, but they easily gain independence, and religious expression is reduced or eliminated in their architecture.

Theatres originated in Greece with the rites of the god Dionysus, first as temporary installations and later as outdoor architecture using the natural slopes and curves of hillsides to bring the spectator close to the stage and to avoid the need for substructures. The Greek theatre was monumentalized and modified by the Romans, whose arches and vaults allowed construction of sloping seats from level foundations. In the middle ages churches and temporary structures were used for dramatic purposes, and in the Renaissance Roman theatres were occasionally revived (Palladio's Teatro Olimpico in Vicenza). The 17th-century development of opera, drama and ballet in Europe brought about a revival of theatre building, but in a new form conceived to satisfy class and economic distinctions (Farnese theatre in Parma; Residenztheater, Munich). A flat or inclined pit accommodated standing patrons, tiers of boxes rose vertically above in a horseshoe plan, and permanent covering (for both acoustics and comfort) made artificial lighting an important feature in theatrical performances. The modern theatre, while greatly improved in efficiency by new acoustical methods and materials, has kept much of the baroque form, though it provides seating throughout and usually substitutes sloping galleries (into which the unprivileged have been moved) for boxes. The motion picture has had little effect on theatre design.

The auditorium is distinguished by the absence of stage machinery and by its greater size. The development of large symphony orchestras and choirs, and of the institution of lectures and mass meetings, combined with growing urban populations to produce this modification of the theatre. (*See* THEATRES [STRUCTURES].)

Sports arenas, race tracks and public swimming pools of the present day owe their origin to the ancient Romans (though certain precedents can be found in Crete and Greece). Although the classical tradition of sports was broken from the early middle ages to the 19th century, even the design of arenas and tracks has been scarcely altered from the Colosseum and Circus Maximus, though the construction of large grandstands has inspired magnificent designs in reinforced concrete (stadiums at Florence, Helsinki and the University of Mexico). Sports that have no precedents in antiquity, such as baseball, have required modifications in design but have not been important for architecture. (*See* AMPHITHEATRE; STADIUM.)

Museum and library architecture was also an innovation of classical antiquity (library architecture appears independently in an-

cient China and Japan). Early examples are found on the Acropolis of Hellenistic Pergamum and in Roman Ephesus. Museums were not cultivated in the middle ages, and libraries were incorporated into monasteries. In the Renaissance and baroque periods library construction was rare, but important civic buildings were designed within religious institutions (Michelangelo's Biblioteca Mediceo-Laurenziana in Florence) and universities (Sir Christopher Wren's Trinity college library, Cambridge; James Gibb's Radcliffe Camera, Oxford). This type of architecture became truly communal for the first time in the 19th century, when the size of library collections and the number of visitors inspired some of the finest architecture of the modern period (G. Bindesboll's Thorwaldsen museum, Copenhagen; Sir Robert Smirke's British Museum in London; Henri Labrouste's Bibliothèque Ste. Geneviève in Paris; Alvar Aalto's library in Viipuri, Finland).

5. Architecture of Welfare and Education.—The principal institutions of public welfare are those that provide facilities for education health, public security and utilities. Some of these functions are performed by the church and the state, but, since their character is not essentially religious or political, they may require independent architectural solutions, particularly in urban environments. A consistent typology of this architecture, however, cannot be established throughout history, because the acceptance of responsibility for the welfare of the community differs in degree in every social system.

Buildings for the specific purposes of public welfare were seldom considered necessary in antiquity, in most of eastern architecture or in the early middle ages. But in Greece health facilities were included in precincts of the god Aesculapius, and in the east within Buddhist precincts. The Romans produced a highly developed system of water supply and sewerage of which their monumental aqueducts are an impressive survival.

In the later middle ages consistent forms began to emerge. With the separation of the university from a purely religious context, a concept of planning developed (particularly at Oxford, Cambridge and Paris) that still influences educational architecture. Hospitals designed as large halls were established as adjuncts to churches, monasteries and convents and gained architectural independence in the Renaissance (Ospedale degli Innocenti, Florence). Ancient and medieval prisons and guardhouses were occasionally isolated from military architecture (Tower of London; Bargello in Florence), but the prison did not become an important architectural type until fairly recent times (George Dance's Newgate prison, London, 1770; Henry Hobson Richardson's Allegheny county jail, Pittsburgh, Pa., 1884).

The expansion of education and health facilities beginning in the 19th century created a widespread and consistently growing need for specialized architectural solutions. Schools, from the nursery to the university, now demand not only particular solutions at all levels but structures for a variety of purposes within each level: advanced education demands buildings for scientific research, training for trades and professions, recreation, health, housing, religious institutions and other purposes. Most of the countries of the western world have produced educational architecture of the highest quality; the type is more important architecturally than in any past age.

6. Commercial and Industrial Architecture.—Buildings for exchange, transportation, communication, manufacturing and power production meet the principal needs of commerce and industry. In the past these needs were mostly unspecialized. They were met either within domestic architecture or in buildings distinguished from domestic types chiefly by their size. Stores, banks, hostelries, guild halls and factories required only space for more persons and things than houses could accommodate. Bridges, warehouses and other structures not used for sheltering people were of course specialized from the beginning and survived the Industrial Revolution without basic changes. This so-called revolution profoundly affected the typology as well as the techniques of architecture. Through the introduction of the machine and mass production, economic life moved out of the domestic environment into an area dominated by devices and processes rather than by individuals, creating the need for buildings more specialized and more numerous than the total accumulation of types throughout history. All the types cannot be discussed here, but a categorical listing into which they can be fitted will illustrate their importance for architecture:

Exchange.—Office buildings, stores, markets, banks, exchanges, warehouses, exhibition halls.

Transportation.—Roads, bridges, tunnels; stations for rail, sea and air transport and the dispensing of fuel; garages, hangars and other storage facilities; hotels.

Communication.—Structures for the transmission and reception of telephone, telegraph, radio, television and radar communication; for the printing and distribution of newspapers, magazines, books and other reading matter; for motion-picture production; and for advertising functions.

Production.—Mines, factories, laboratories, food processing plants.

Power.—Dams, generating plants; fuel storage, processing and distribution installations.

Each of these functions demands its own architectural solution, but in general they may be divided into two classes according to whether the plan must give greater attention to the size and movement of machinery or of persons. Wherever human activity is the chief concern, there has been less departure from traditional expression; banks in the form of Roman temples are an obvious example. The demands of machines have no tradition and have encouraged a search for greater, simpler and more flexible spaces; but frequently the practical function has entirely eliminated the expressive, so that, with some distinguished exceptions (Frank Lloyd Wright's S. C. Johnson & Son building, Racine, Wis.; Eero Saarinen's General Motors Technical centre, Warren, Mich.) most modern factories are not architecture. Where both men and machines must be given equal attention, as in railroad stations, architecture of the 19th and 20th centuries has vacillated between creating new forms and grasping for irrelevant traditions. (*See* INDUSTRIAL ARCHITECTURE.)

B. PLANNING

The architect usually begins to work when the site and the type and cost of a building have been determined.

The site involves the varying behaviour of the natural environment that must be adjusted to the unvarying physical needs of human beings; the type is the generalized form established by society that must be adjusted to the special use for which the building is required; the cost implies the economics of land, labour and materials that must be adjusted to suit a particular sum.

Thus planning is the process of particularizing and, ultimately, of harmonizing the demands of environment, use and economy. This process has a cultural as well as a utilitarian value, for in creating a plan for any social activity the architect inevitably influences the way in which that activity is performed.

1. Planning the Environment.—The natural environment is at once a hindrance and a help, and the architect seeks both to invite its aid and to repel its attacks. To make buildings habitable and comfortable, he must control the effects of heat, cold, light, air, moisture and dryness, and foresee destructive potentialities such as fire, earthquake, flood and disease.

The methods of controlling the environment considered here are only the practical aspects of planning. They are treated by the architect within the context of the expressive aspects. The placement and form of buildings in relation to their sites, the distribution of spaces within buildings, and other planning devices discussed below are fundamental elements in the aesthetics of architecture.

Orientation.—The arrangement of the axes of buildings and their parts is a device for controlling the effects of sun, wind and rainfall. The sun is regular in its course; it favours the southern and neglects the northern exposures of buildings in the northern hemisphere, so that it may be captured for heat or evaded for coolness by turning the axis of a plan toward or away from it. Within buildings, the axis and placement of each space determines the amount of sun it receives. Orientation may control air for circulation and reduce the disadvantages of wind, rain and snow, since in most

climates the prevailing currents can be foreseen. The characteristics of the immediate environment also influence orientation: trees, land formations and other buildings create shade and reduce or intensify wind, while bodies of water produce moisture and reflect the sun.

Design.—Planning may control the environment by the design of architectural forms that may modify the effects of natural forces. For example, overhanging eaves, moldings, projections, courts and porches give shade and protection from rain. Roofs are designed to shed snow and to drain or preserve water. Protective walls around buildings limit wind, light and heat.

Fenestration.—Windows are the principal means of controlling natural light; its amount, distribution, intensity, direction and quality are conditioned by their number, size, shape and placement and by the characteristics of translucent materials (thickness, transparency, texture, colour). But the planning of fenestration is influenced by other factors, such as ventilation and heating. Since most translucent materials conduct heat more readily than the average wall, windows are used sparingly in extreme climates. Finally, since transparent windows are the medium of visual contact between the interior and exterior, their design is conditioned by aesthetic and practical demands. (*See* WINDOW.)

Walls.—Walls control the amount of heat lost to the exterior or retained in the interior by their thickness and by the structural and insulating materials used in making them. Walls, when properly sealed and protected, are the chief defense against wind and moisture.

Colour.—Colour has a practical planning function as well as an expressive quality because of the range of its reflection and its absorption of solar rays. Since light colours reflect heat and dark colours absorb it, the choice of materials and pigments is an effective tool of environmental control.

Materials and Techniques.—The choice of materials is conditioned by their own ability to withstand the environment as well as by properties that make them useful to human beings. One of the architect's jobs is to find a successful solution to both conditions: to balance the physical and economic advantages of wood against the possibility of fire, termites and mold, the weather resistance of glass and light metals against their high thermal conductivity, and many similar conflicts. The more violent natural manifestations such as heavy snow loads, earthquakes, high winds and tornadoes are controlled by specific technical devices in regions where they are prevalent.

Any number of these controls may be out of reach of the planner for various reasons. The urban environment, for example, restricts freedom of orientation, design, fenestration, etc., and creates new control problems of its own: smoke, dirt, noise and odours.

Interior Control.—The control of the environment through the design of the plan and the outer shell of a building cannot be complete, since extremes of heat and cold, light and sounds penetrate into the interior, where they can be further modified by the planning of spaces and by special conditioning devices.

Temperature, light and sound are all subject to control by the size and shape of interior spaces, the way in which the spaces are connected and the materials employed for floors, walls, ceilings and furnishings. Hot air may be retained or released by the adjustment of ceiling heights and sources of ventilation. Light reflects in relation to the colour and texture of surfaces and may be reduced by dark, rough walls and increased by light, smooth ones. Sounds are transmitted by some materials and absorbed by others and may be controlled by the form of interiors and by the use of structural or applied materials that by their density, thickness and texture amplify or restrict sound waves.

Conditioning devices played a small part in architecture before the introduction of mechanical and electrical systems in the 19th century. The fireplace was almost the only method of temperature control (though the Romans anticipated the modern water system for radiant heating); fuel lamps and candles had to be movable and were rather in the sphere of furnishings than of architecture; the same is true of the tapestries and hangings used for acoustical purposes.

Today, heating, insulation, air conditioning, lighting and acoustical methods have become basic parts of the architectural program. These defenses and comforts of industrialization control the environment so efficiently that the contemporary architect is free to use or to discard most of the traditional approaches to site and interior planning.

2. Planning for Use.—While environmental planning produces comfort for the senses (sight, feeling, hearing) and reflexes (respiration), planning for use is concerned with convenience of movement and rest. All activities that demand architectural attention require unique planning solutions to facilitate them. These solutions are found by differentiating spaces for distinct functions, by providing circulation among these spaces and by designing them to facilitate the actions of the human body.

Differentiation.—The number of functions requiring distinct kinds of space within a building depends not only upon the type of building but also upon the requirements of the culture and the habits and activities of the individual patrons. A primitive house has a single room with a hearth area, and a modern one has separate areas for cooking, eating, sleeping, washing, storage and recreation. A meeting house with a single hall is sufficient for Quaker religious services, while a cathedral may require a nave, aisles, choir, apse, chapels, crypt, sacristy and ambulatory.

The planning of differentiated spaces involves as a guide to their design (placement, size, shape, environmental conditions, sequence, etc.) the analysis of use (number of uses and character, duration, time of day, frequency, variability, etc., of each), users (number, behaviour, age, sex, physical condition, etc.) and furniture or equipment required.

Circulation.—Communication among differentiated spaces and between the exterior and the interior may be achieved by openings alone in the simplest plans, but most buildings require distinct spaces allotted to horizontal and vertical circulation (corridors, lobbies, stairs, ramps, elevators). These are designed by the procedure of analysis employed for differentiating uses. Since their function is usually limited to simplifying the movement of persons and things toward a particular goal, their efficiency depends on making the goal evident and the movement direct and easy to execute.

Facilitation.—The convenience of movement, like the comfort of environment, can be increased both by planning and by devices. Planning methods are based on analysis of the body measurements, movements and muscular power of human beings of different ages and sexes, which results in the establishment of standards for the measurements of ceilings, doorways, windows, storage shelves, working surfaces, steps and the like, and for the weight of architectural elements which must be moved, such as doors, gates and windows. These standards also include allowances for the movement of whatever furnishings, equipment or machinery are required for the use of any building. Devices for facilitating movement within buildings replace or simplify the labours of daily life: the traditional pumps, plumbing and sewerage systems and the innumerable modern machines for circulation, food preparation and preservation, industrial processing and other purposes.

3. Economic Planning.—Major expenses in building are for land, materials and labour. In each case they are high when the commodity is scarce and low when it is abundant, and they influence planning more directly when they become restrictive.

The effect of high land values is to limit the amount of space occupied by any building as well as the amount of expenditure that can be reserved for construction. When land coverage is limited, it is usually necessary to design in height the space that otherwise would be planned in breadth and depth, as in the ancient Roman insula (apartment house) or the modern skyscraper. When the choice of materials is influenced by cost, all phases of architectural design are affected, since the planning procedure, the technique and the form of buildings are dependent on materials. High labour costs influence the choice of techniques and, consequently, of materials. They encourage simplification in construction and the replacement of craftsmanship by standardization. The development of light wood frame construction and methods of prefabrication were largely the result of the rising cost of labour.

Planning involves not only the control of cost in each area but

Street in Pom[illegible] buried under volcanic lapilli and ash in A.D. 79

DOMESTIC ARCHITECTURE

Domestic architecture is produced to provide shelter and security for the social unit. The houses that lined Pompeian streets (left), built two millennia ago, are characteristic of "vernacular architecture," single-unit dwellings which tend to remain virtually unchanged for centuries; the Pompeian houses are little different from those built in small towns around the Mediterranean today. "Power architecture," symbolizing the might of the ruler, is represented here by the palace of Versailles (above), which once housed thousands of servants, soldiers, and courtiers, as well as the royal family of France. Group housing (below) provides homes for many families and is at once public and private

RECREATIONAL ARCHITECTURE

Perhaps the most unchanging structures in architectural history have been those used for recreation. While the diversions which draw people to public entertainments change, man's basic recreational interests remain the same: if his participation is passive, he wants to be comfortable and to be able to see and hear; if active, he wants suitable space in which to perform or compete. Thus the three theatres on this Plate, though built in the 1st or 2nd, 17th and 19th centuries, are remarkably similar in design; and the 19th-century British Museum (below) had antecedents in ancient Greece and Rome.

ARCHITECTURE

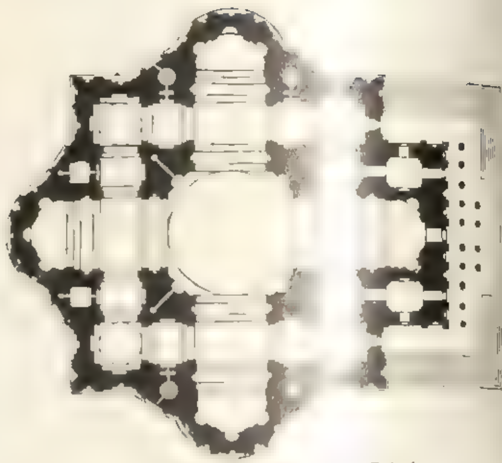
Colonnade of St. Peter's, Rome, designed by Bernini; 1656–67



Michelangelo's plan for St. Peter's

ARCHITECTURAL SYMBOLISM

Architecture conveys meaning through shape. Thus Michelangelo's plan for St. Peter's in Rome (above) combines the cross, the traditional Christian symbol, with the universal religious symbol, the circle. The most important symbols of elevation have been the colonnade, stairway, portal, dome, and tower. The colonnade (left) and stairway (bottom left, and below) serve to heighten the importance of what lies at their end, as the monumental portal (Plate VII, center left) magnifies the importance of what lies beyond it. Both the dome (Plate VII, top left) and the tower (Plate VII, top right, and bottom) have traditionally symbolized both religious and secular power in a wide variety of cultures

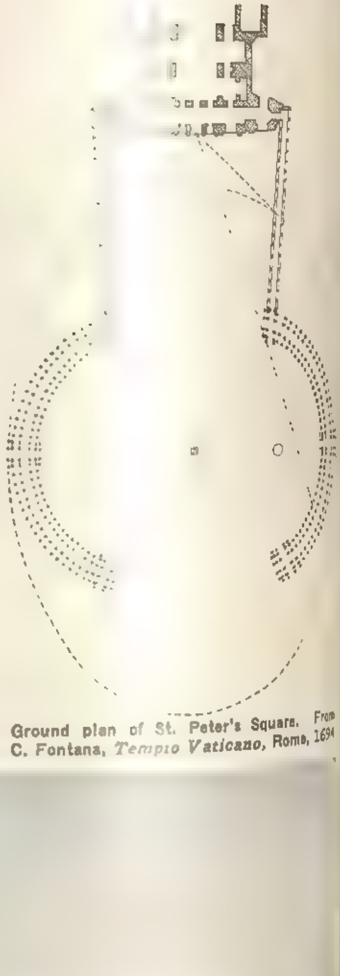
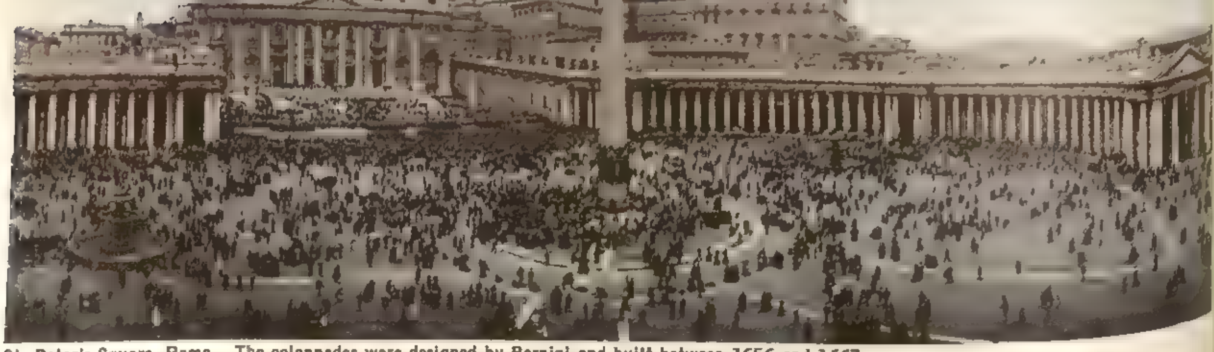
Mont-Saint-Michel, France. The abbey was founded in the 8th century and built and rebuilt over a period of several centuries

COMPOSITION

The harmonious arrangement of planes, surfaces and spaces and their intersections is the basis of all great architecture and has traditionally been achieved in two equally expressive ways. The Gothic abbey of Mont-Saint-Michel (above), which stands atop a granite islet a mile off the Normandy coast, is a handsome example of asymmetry. Successful symmetry is seen in the Baroque piazza of St. Peter's in Rome (right and below), with its semicircular colonnades that lead the eye to the perfectly symmetrical church itself



Ground plan of St. Peter's Square. From C. Fontana, *Tempio Vaticano*, Rome, 1694



St. Peter's Square, Rome. The colonnades were designed by Bernini and built between 1656 and 1667

Dome of St. Peter's Rome; designed by Michelangelo; completed 1590

LIGHT

Although it is the most ephemeral means of architectural expression, light is also among the most powerful. On this Plate are shown two examples of its dramatic use. The light that streams in from the dome of St. Peter's makes the dome seem even loftier than it is. In Gothic churches such as Sainte-Chapelle (below) the magnificent stained-glass windows make the walls themselves seem to dissolve and disappear.

ARCHITECTURE

Interior of Hagia Sophia; Istanbul 532–537

SPACE AND MASS

The monuments on this Plate show extreme cases of what is meant by space and mass in architecture. The 6th-century Byzantine church of Hagia Sophia (right), like most Byzantine monuments, is a shell which holds and forms a soaring space. The Mayan temples (below) at Tikal, Guatemala, atop towering pyramids, contain no meaningful space and depend almost entirely on the expression of mass; they are sculptural rather than architectural in effect

also the proportioning of expenditures among land, materials and labour in order to produce the most effective solution to an architectural problem.

II. TECHNIQUES

The techniques of architecture in the sense that they will be considered here are simply the methods by which structures are formed from particular materials. These methods are influenced not only by the availability and character of materials but also by the total technological development of society. For architecture depends on an organized labour force and upon the existence of the tools and skills necessary to secure, manufacture, transport and work durable materials.

The evolution of techniques is conditioned by two forces. One is economic—the search for a maximum of stability and durability in building with a minimum of materials and labour. The other is expressive—the desire to produce meaningful form. Techniques evolve rapidly when economic requirements suggest new expressive forms or when the conception of new forms demands new procedures. But they remain static when architects avoid the risk of pioneering with untried and possibly unsuccessful methods and depend instead on proved procedures, or when the need for the observance of tradition, for the communication of ideas or for elegance and display is best fulfilled by familiar forms.

The ultimate purpose of building techniques is to create a stable structure. In mechanical terms, structures are stable when all their parts are in a state of equilibrium or rest. Walls and roofs can buckle, crack or collapse if they are not properly designed. These movements are caused by forces which tend to push or pull bodies in a given direction. Forces acting on any member (part) of a building are, first, its own weight and, second, the loads it carries, principally from other members but also from persons, furnishings, wind, etc. Their action encounters a reaction in opposing forces that hold the member in place by resisting at its joints. These forces may be active in all directions, and they must always be balanced for stability. They tend to crush, pull apart and bend the member—in other words, to change its size and shape.

Within the member itself there are forces, too, that tend to resist any deformation. They are called stresses, and they vary according to the strength of materials and the form of the member. The kinds of stress under consideration are compression, which resists crushing; tension, which resists pulling apart; and bending, which occurs when one part of a member is in compression and the other is in tension. A column (fig. 1) is put into compression by the loads it carries; in a trussed roof (fig. 13), the piece that forms the base of the triangle is put into tension by the outward-pushing forces in the sides; and a lintel or beam (the member that spans a space) is put into bending by loads and forces that push down on its top and encounter a reacting force at its ends (figs. 1 and 15). Some materials are strong only in compression (stone, brick, cast iron, concrete), and others in tension as well (wood, steel, reinforced concrete), so the latter are more efficient in resisting bending forces.

Finally, the stability of the total structure whose single members are all in equilibrium is achieved by diverting the loads from all of them downward so that they may be resisted by the upward-supporting forces of the ground.

Techniques will be discussed in terms of the characteristics of building materials and the methods by which they are used in architecture.

A. MATERIALS

1. Stone.—In most areas where stone is available, it has been favoured over other materials for the construction of monumental architecture. Its advantages are durability, adaptability to sculptural treatment and the fact that it can be used in modest structures in its natural state. But it is difficult to quarry, transport and cut, and its weakness in tension limits its use for beams, lintels and floor supports.

The simplest and cheapest stonework is rubble, roughly broken stones of any shape bonded in mortar. The strongest and most suitable stonework for monumental architecture is ashlar masonry, which consists of regularly cut blocks (usually rectangular). Because of its weight and the precision with which it can be shaped, stone masonry (in contrast with brick) does not depend on strong bonding for stability where it supports only direct downward loads. Entablatures of Greek temples, for example, are bonded by small bronze dowels. But the weight creates problems of stability when loads push at an angle: stone vaults and arches require more support and buttressing than equivalent forms in other materials.

The best stone (and brick) bonding is that in which blocks are placed so that the vertical joints in one course are not above the joints in the courses above and below, since the stone resists deformation better than any bonding material. Many stones are strong enough to provide monolithic supports (columns and piers) and beams (lintels); and in some styles stone slabs are employed even for roofing (Egyptian temples, early Syrian basilicas). But this roofing requires so many columns that unvaulted masonry buildings are almost always combined with floors and covering in wood. Stone has been consistently used for building since the Stone Age (Stonehenge in England). Although it has generally been replaced as a structural material by cheaper and more efficient manufactured products, it is still widely used as a surface veneer for its practical and expressive qualities. (*See* STONE.)

2. Brick.—Brick compares favourably with stone as a structural material for its fire- and weather-resisting qualities and for the ease of production, transportation and laying. The size of bricks is limited by the need for efficient drying, firing and handling, but shapes, along with the techniques of bricklaying, have varied widely throughout history. Special shapes can be produced by molding to meet particular structural or expressive requirements (for example, wedge-shaped bricks are sometimes employed in arch construction, and bricks with rounded faces in columns). Bricks may be used in construction only in conjunction with mortar, since the unit is too small, too light and too irregular to be stabilized by weight. Each course must be laid on an ample mortar bed with mortar filling the vertical joints. The commonest Roman bricks were cut into triangles and laid with the base out and the apex set into a concrete filling that provided additional strength. Rectangular bricks are bonded either as "headers" (short side out) or "stretchers" (long side out). Standard modern types provide a ratio of width to length of slightly less than 1:2 to permit a wide variety of bonding patterns within a consistent module, or standard of measurement. Brick, which has been used since the fourth millennium B.C., was the chief building material in the ancient near east. The versatility of the medium was expanded in ancient Rome by improvements in the manufacture of both bricks and mortar and by new techniques of laying and bonding. Employed throughout the middle ages, brick gained greater popularity from the 16th century on, particularly in northern Europe and Great Britain. It is widely used today, often for nonbearing walls in steel frame construction. (*See* BRICKWORK.)

3. Wood.—Wood is easier to acquire, transport and work than other natural materials. All parts of a building can be efficiently constructed of wood except foundations; its disadvantages are susceptibility to fire, mold and termites. The strength of wood in both tension and compression arises from its organic nature, which gives it an internal structure of longitudinal and radial fibres that is not impaired by cutting or long exposure. But like all organisms it contains moisture and is not uniformly strong, so it must be carefully selected and seasoned to prevent warping, splitting and failure under loads. Wood is used in building both solid and skeletal structures. The principal solid system, called log construction, is employed when only primitive cutting tools are available. Four walls must be built up together in horizontal layers of single hewn or uncut logs and jointed at the corners. The stability of the log building depends entirely on the mutual support of the walls, and the method is suitable only for simple structures of limited size. The skeletal system requires precise cutting and shaping of lumber. It provides a rigid framework of jointed or nailed members (fig. 14) independent of the walls, which are attached to the exterior and interior surfaces after completion.

Almost all masonry buildings of the past had wood floors and

coverings, since wood is the lightest, the most practical and the most inexpensive material for spanning spaces.

The monumental architecture of the west has typically employed materials rarer than wood for expressive purposes, but the history of wood construction can be traced consistently in China and Japan and in the domestic architecture of northern Europe and North America. Wood continues to be used in a growing number of techniques and products: heavy framing systems with compound beams and girders, interior and exterior facing with plywood and other composite panels, and arch and truss systems with laminated members that can be designed to meet particular structural demands.

4. Iron and Steel.—The development of construction methods in iron and steel was the most important innovation in architecture since ancient times. These methods provide far stronger and taller structures with less expenditure of material than stone, brick or wood and can produce greater unsupported spans over openings and interior or exterior spaces. The evolution of steel frame construction in the 20th century entirely changed the concept of the wall and the support.

In architecture before 1800, metals played an auxiliary role. They were used for bonding masonry (dowels and clamps), for tension members (chains strengthening domes, tie rods across arches) and for roofing, doors, windows and decoration. Cast iron, the first metal that could be substituted for traditional structural materials, was used in bridgebuilding as early as 1779. Its ability to bear loads and to be produced in an endless variety of forms, in addition to its resistance to fire and corrosion, quickly encouraged architectural adaptations, first as columns and arches, and afterward in skeletal structures. Because cast iron has much more compressive than tensile strength (for example, it works better as a small column than as a beam), it was largely replaced in the late 19th century by steel, the product of improved purification processes (Bessemer furnace, open hearth). Steel is more uniformly strong, more elastic and workable, and its high resistance in all stresses can be closely calculated.

Steel structural members are rolled in a variety of shapes, the commonest of which are plates, angles, I beams and U-shaped channels. These members may be joined by steel bolts or rivets, and the development of welding in the 20th century made it possible to produce fused joints with less labour and materials. The result is a rigid, continuous structure in which the joint is as firm as the member and which distributes stresses between beams and columns (fig. 15). This is a fundamental change in architectural technique, the effect of which cannot yet be estimated.

Normally, steel must be protected against corrosion by surface coverings, but alloys such as stainless steel have been developed for exposed surfaces, and these alloys may even be used in exterior curtain walls. Aluminum and other light metal alloys have come to be favoured for curtain-wall construction because of their weather resistance. (*See* also Ironwork.)

5. Concrete.—Concrete is a manufactured mixture of cement and water, with aggregates of sand and stones, which hardens rapidly by chemical combination to a stonelike, water- and fire-resisting solid of great compressive (but low tensile) strength. Because it can be poured into forms while liquid to produce a great variety of structural elements, it provides an economical substitute for traditional materials, and it has the advantages of continuity (absence of joints) and of fusing with other materials.

Concrete was employed in Egypt and was highly developed by the Romans, whose concrete made with volcanic ash cement (pozzolana) permitted a great expansion of architectural methods, particularly the development of domes and vaults (often reinforced by brick ribbing) to cover large areas, of foundations and of structures such as bridges and sewerage systems where waterproofing was essential. The technique of manufacture declined in the middle ages and was regained in the 18th century, but concrete had a limited importance for architecture until the invention of reinforced concrete (*q.v.*) in the 1860s.

Reinforced concrete was developed to add the tensile strength of steel to the compressive strength of mass concrete. The metal is embedded by being set as a mesh into the forms before pouring, and in the hardened material the two act uniformly. The combination is much more versatile than either product; it serves not only for constructing rigid frames but also for foundations, columns, walls, floors and a limitless variety of coverings, and it does not require the addition of other structural materials. Although the making of the forms is a slow and costly process, the technique competes economically with steel frame construction because the mesh, composed of thin, bendable rods or metal fabric, employs far less steel, and concrete is itself inexpensive.

The steel reinforcement is employed to take full advantage of the plastic character of concrete. It can be jointed or bent to unify supporting members with the floors and coverings they carry. Furthermore, stresses produced in floors, domes and vaults may be distributed within the slabs themselves to reduce load, and the diminished load may be concentrated at desired points so that the number and size of supports is greatly reduced.

Three 20th-century developments in production are destined to have a radical effect on architecture. The first, concrete shell construction, permits the erection of vast vaults and domes with a concrete and steel content so reduced that the thickness is comparatively less than that of an eggshell. The second development, precast concrete construction, employs bricks, slabs and supports made under optimal factory conditions to increase waterproofing and solidity, to decrease time and cost in erection and to reduce expansion and contraction. Finally, prestressed concrete provides bearing members into which reinforcement is set under tension to produce a live force to resist a particular anticipated load. Since the member acts like a spring, it can carry a greater load than an unstressed member of the same size. (*See* also Concrete.)

B. Methods

1. Wall.—The two types of wall are (1) load bearing, which supports the weight of floors and roofs; and (2) nonbearing, which at most supports its own weight.

The load-bearing wall of masonry is thickened in proportion to the forces it has to resist: its own load, the load of floors, roofs, persons, etc., and the lateral forces of arches, vaults, wind, etc., that may cause it to crack or buckle. Its thickness often can be reduced at the top, because loads accumulate toward the base; in high buildings this is done by interior or exterior setbacks at the floor level of upper stories. Walls that must resist lateral forces are either thickened along the whole length or at particular points where the force is concentrated. The latter method is called buttressing. Doors and windows weaken the resistance of the wall and divert the forces above them to the parts on either side, which must be thickened in proportion to the width of the opening. In multistory buildings, windows—unless they are very small—must be placed one above the other so as to leave uninterrupted vertical masses of wall between them to transfer loads directly to the ground. The number of openings that can be used depends on the strength of the masonry and the stresses in the wall. Walls in light, wood-framed structures and in reinforced-concrete construction may have a bearing function also. But the nature of the material admits other means of resisting forces than the increase of mass.

The placement of walls is determined by the type of support for floors and roofs. The commonest support is the beam, which must be jointed to walls at both ends; consequently, its maximum permissible length establishes the distance between bearing walls. All floors and coverings are most easily supported on straight, parallel walls except the dome (*see* below).

The nonbearing wall (excluding the independent garden variety) appears only where loads are carried by other members, as in heavy timber and other skeletal structures. Modern steel and reinforced-concrete frames require exterior walls only for shelter, and sometimes dispense with them on the ground floor to permit easier access. Since the wall rests or hangs upon members of the frame, it becomes a curtain or screen and admits treatment in any durable, weather-resisting material. Traditional materials are often used, but light walls of glass, plastic, metal alloys, wood products, etc., can be equally efficient. This freedom of choice extends also to the form of walls and offers greatly expanded opportunities for creative expression.

2. Post and Lintel.—The simplest illustration of load and

support in construction is the post and lintel system, in which two upright members (posts, columns, piers) hold up a third member (lintel, beam, girder, rafter) laid horizontally across their top surfaces (fig. 1). This is the basis for the evolution of all openings. But in its pure form, the post and lintel is seen only in colonnades and in framed structures, since the posts of doors, windows, ceilings and roofs are part of the wall.

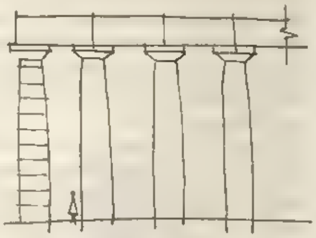

FIG. 1.—POST AND LINTEL

Stone construction; the Parthenon, Athens, 5th century B.C.

The job of the lintel is to bear the loads that rest on it (and its own load) without deforming or breaking. Failure occurs only when the material is too weak or the lintel is too long. Lintels composed of materials that are weak in bending, such as stone, must be short, while lintels in materials that are strong in bending, such as steel, may span far greater openings. Masonry lintels are inefficient because they must depend on the cohesiveness of mortar, which is weaker than the blocks it bonds; so in masonry construction, lintels of monolithic (single slab) stone, wood and stronger materials are employed.

The job of the post is to support the lintel and its loads without crushing or buckling. Failure occurs, as in lintels, from excessive weakness or length, but the difference is that the material must be especially strong in compression. Stone, which has this property, is more versatile as a post than as a lintel; under heavy loads it is superior to wood but not to iron, steel or reinforced concrete. Masonry posts, including those of brick, may be highly efficient, since the loads compress the joints and add to their cohesiveness. Although monolithic stone columns are used, they are extravagant to produce for large structures, and columns are usually built up of a series of cylindrical blocks called drums.

From prehistoric times to the Roman empire, the post and lintel system was the root of architectural design. The interiors of Egyptian temples and the exteriors of Greek temples are delineated by columns covered by stone lintels. The Greeks opened their interior spaces by substituting wooden beams for stone, since the wood required fewer supports. The development of the arch and vault challenged the system but could not diminish its importance either in masonry construction or in wood framing, which by its nature is dependent on posts and beams (fig. 14).

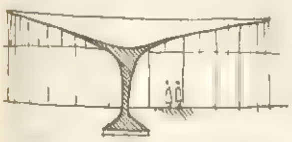

FIG. 2.—POST AND LINTEL

Reinforced concrete construction; restaurant, the Lido, Rome, by P. L. Nervi, 20th century

Ancient uses of the post and lintel were refined but not fundamentally altered until the production of cast-iron columns, which, offering greater strength and smaller circumference, greatly reduced the mass and weight of buildings. Much construction in modern materials is based on the post and lintel system of the past. Steel and concrete skeletons restore to modern architecture the formal simplicity of the oldest structures known. But, because they are rigid frames, they abandon the fundamental concept of the duality of post and lintel by fusing them into a unit throughout which stresses are distributed. The "mushroom" column is a further departure, since the unit can be extended into a covering slab and becomes a ceiling as well as a support (fig. 2).

3. Arch.—The arch can be called a curved lintel. Early masonry builders could span only narrow openings because of the necessary shortness and weight of monolithic stone lintels. With the invention of the arch, two problems were solved: (1) wide openings could be spanned with small, light blocks, in brick as well as stone, which were easy to transport and to handle; (2) the arch was bent upward to resist and to conduct into its supports the loads that tended to bend the lintel downward. Because the arch is curved, the upper edge has a greater circumference than the lower, so that each of its blocks must be cut in wedge shapes that press firmly against the whole surface of neighbouring blocks and conduct loads uniformly (fig. 3). This form creates problems of equilibrium that do not exist in lintels. The stresses in the arch tend to squeeze the blocks outward radially, and loads divert these outward forces downward to exert a resultant diagonal force, called thrust, which will cause the arch to collapse if it is not properly buttressed. So an arch cannot replace a lintel on two free-standing posts unless the posts are massive enough to buttress the thrust and to conduct it into the foundations (as in Roman triumphal arches). Arches may rest on light supports, however, where they occur in a row, because the thrust of one arch counteracts the thrust of its neighbours, and the system will remain stable as long as the arches at either end of the row are buttressed by walls, piers or (as in fig. 4) earth.

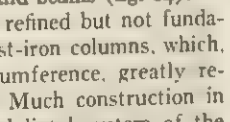

FIG. 3.—THE ARCH

Basic construction, showing direction of thrust

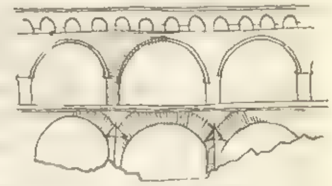

FIG. 4.—THE ARCH

Stone construction; the Pont du Gard, Nîmes, France, early imperial Roman

The size of arches is limited only by economy; large arches exert large thrusts, and they are hard to buttress and to build. The form may be varied to meet specific problems; the most efficient forms in masonry are semicircular, segmental (segment of a circle) and pointed (two intersecting arcs of a circle), but noncircular curves can be used successfully.

Arches were known in Egypt and Greece but were considered unsuitable for monumental architecture. In Roman times the arch was fully exploited in bridges, aqueducts (fig. 4) and large-scale architecture. New forms and uses were found in medieval and particularly Gothic architecture (flying buttress, pointed arch), and baroque architects developed a vocabulary of noncircular forms for expressive reasons.

Steel, concrete and laminated wood arches of the present day have changed the concept and the mechanics of arches. Their components are completely different from wedge-shaped blocks; they may be made entirely rigid so as to require only vertical support; they may be of hinged intersections that work independently, or they may be thin slabs or members (in reinforced concrete) in which stresses are so distributed that they add the advantages of lintels to those of arches, requiring only light supports (fig. 5). These innovations provide a great freedom of design and a means of covering great spans without a massive substructure.

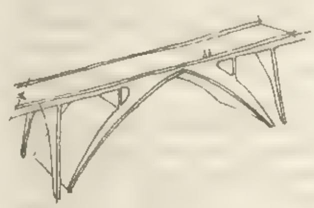

FIG. 5.—THE ARCH

Reinforced-concrete construction: bridge over the Thur river, Switz., by R. Maillart, 20th century

4. Vault.—The evolution of the vault begins with the discovery of the arch, because the basic "barrel" form which appeared first in ancient Egypt and the near east (fig. 6) is nothing more than an arch deep enough to cover a three-dimensional space. Since the barrel vault exerts thrust as the arch does, it must be buttressed along its entire length by heavy walls in which openings must be limited in size and number. This is a disadvantage, since it inhibits light and circulation.

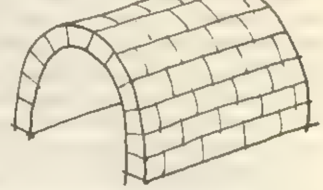

FIG. 6.—THE VAULT

Barrel construction

But Roman builders discovered that openings could be made by building two barrel vaults that intersected at right angles to form the groin vault (fig. 7), which is square in plan and may be repeated in series to span rectangular areas of unlimited length. This vault has the additional advantage that its thrusts are concentrated at the four corners, so that the supporting walls need

not be uniformly massive but may be buttressed where they support the vault.

Two disadvantages of the groin vault encouraged Gothic builders to develop a modification known as the rib vault (fig. 8). First, to build a groin vault, a form must be made to pour or lay the entire vault, and this requires complex scaffolding from the ground up; second, the groin vault must be more or less square and a single vault cannot span extended rectangular areas. The rib vault provided a skeleton of arches or ribs along the sides of the area and crossing it diagonally; on these the masonry of the vault could be laid; a simple centring sufficed for the ribs. To cover the rectangular areas, the medieval mason used pointed arches, which, unlike round arches, can be raised as high over a short span as over a long one. Thus the vault could be composed of the intersection of two vaults of different widths but the same height.

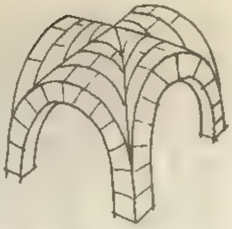

FIG. 7.—THE VAULT
Groin construction

To reduce further the thickness of the wall (to the point of substituting large areas of glass for masonry) Gothic builders developed the flying buttress, which counteracts vault thrust not by continuous wall mass and weight but by counterthrust created by exterior half-arches placed at the height of the vaults at the points of greatest stress. These buttresses conduct stresses to heavier wall buttresses below the window level.

The next important development in vaults, as in arches, came with 19th-century materials. Great iron skeleton vaults were constructed as a framework for light materials such as glass (Crystal palace, London, 1851). The elimination of weight and excessive thrust, the freedom in the use of materials and the absence of centring problems favoured the simple barrel vault and made more complex types obsolete. But in many of the modern frame systems the vault itself loses its structural function and becomes a thin skin laid over a series of arches.

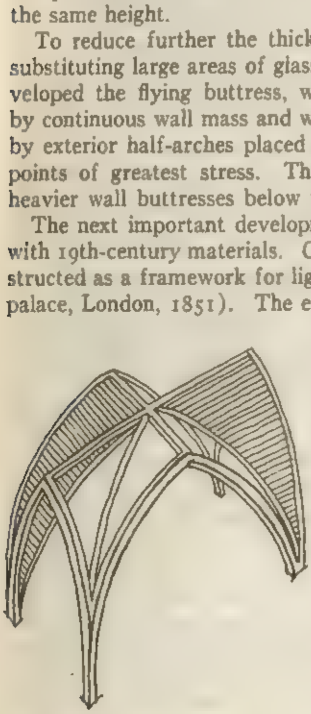

FIG. 8.—THE VAULT
Rib construction

While the arch is supplanting the vault in one area of technique, the vault has abandoned the arch principle in another. The reinforced-concrete shell vault, based on the principle of the bent or molded slab, is one of the most important innovations in the history of architecture. It has all the advantages of load distribution of the concrete floor slab, plus the resistance to bending provided by its curved form. The shell is reinforced in such a way that it exerts no lateral thrust and may be supported as if it were a beam or a truss (fig. 9). So the form no longer is controlled by the necessity to conduct loads into the wall, and the vault may be designed with great freedom. (*See* ARCH AND VAULT.)

FIG. 9.—THE VAULT
Reinforced-concrete construction: a laboratory at the National University of Mexico, Mexico City, by J. González Reyna, 20th century

5. Dome.—Domes appeared first on round huts and tombs in the ancient near east, India and the Mediterranean, but as solid mounds or in techniques adaptable only to the smallest buildings. They became technically significant with the introduction of the large-scale masonry hemisphere by the Romans. Domes, like vaults, evolved from the arch, for in their simplest form they may be thought of as a continuous series of arches, with the same centre. Therefore the dome exerts thrusts all around its perimeter, and the earliest monumental examples (fig. 10) required heavy walls. Since the walls permitted few openings and had to be round or polygonal to give continuous support, early domes were difficult to incorporate into complex structures, especially when adjacent spaces were vaulted.

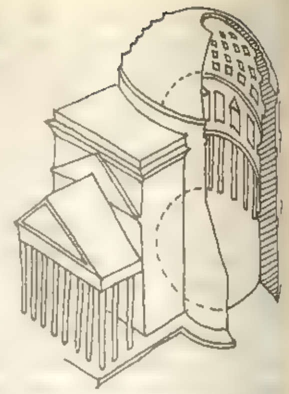

FIG. 10.—THE DOME
Construction on a circular plan; the Pantheon, Rome, 1st–2nd century

Byzantine architects perfected a way of raising domes on piers instead of walls (like groin vaults), which permitted lighting and communication from four directions. The transition from a cubic plan to the hemisphere was achieved by four inverted spherical triangles called pendentives—masses of masonry curved both horizontally and vertically (fig. 11). Their apexes rested on the four piers, to which they conducted the forces of the dome; their sides joined to form arches over openings in the four faces of the cube; and their bases met in a complete circle to form the dome foundation. The pendentive dome could rest directly on this circular foundation or upon a cylindrical wall, called a drum, inserted between the two to increase height.

The dome was unsuited to the lightness and verticality of late medieval styles but was widely used in the Renaissance and baroque periods. Renaissance builders adapted the Gothic rib system to dome construction and found new means to reduce loads and thrust (concentric chains, etc.) that permitted high drums and variations in the curvature of the dome. The awkward, tunnel-like effect produced on the interior by high domes was often hidden by an internal shell built on the same foundations.

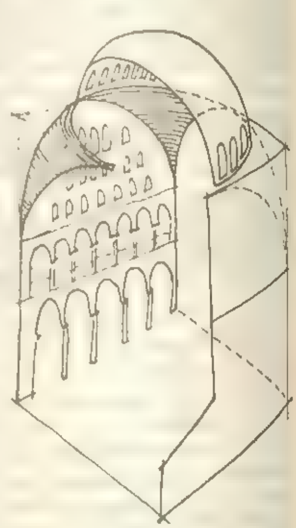

FIG. 11.—THE DOME
Pendentive construction; Hagia Sophia, Constantinople, 6th century

The effort and ingenuity devoted to doming rectangular buildings can be explained principally by the symbolic character of the form, since vaulting is a simpler alternative. So it was chiefly the desire to observe tradition that preserved the dome in the early era of iron and steel construction, and with rare exceptions (Halle aux Blés, Paris; the Coal Exchange, London) 19th-century examples retained masonry forms without exploiting the advantages of metal.

Newer techniques, however, have added practicality to the expressive advantages of domes. The reinforced concrete slab used in vaulting can be curved in length as well as width (like an inflated handkerchief or a parachute). And in this development the distinction between vaults and domes loses significance, being based on nothing but the type of curvature in the slab. Geodesic domes, developed by Buckminster Fuller, are spherical forms in which triangular or polygonal facets composed of light skeletal struts or flat planes replace the arch principle and distribute stresses within the structure itself, as in a truss (fig. 12). Geodesic domes can be supported by light walls and are the only

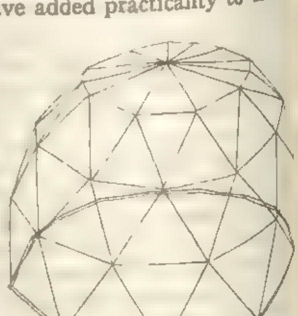

FIG. 12.—THE DOME
Geodesic construction by B. Fuller, 20th century

large domes that can be set directly on the ground as complete structures. (*See* also DOME.)

6. **Truss.**—By far the commonest covering throughout history is the trussed roof, constructed upon a frame composed of triangular sections spaced crosswise at intervals and made rigid in length by beams. Trusses formerly were principally of wood (fig. 13) and were used to cover masonry as well as framed structures, even when these were vaulted. The variety of trusses is so great that only the general principle of the form can be given here.

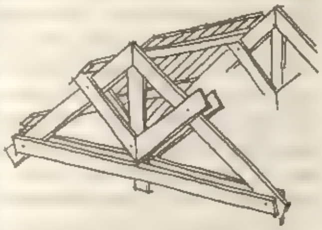

FIG. 13.—THE TRUSS
Traditional wood construction

The truss is based on the geometric law that a triangle is the only figure that cannot be changed in shape without a change in the length of its sides. So a triangular frame of strong pieces firmly fastened at the angles cannot be deformed by its own load or by external forces such as wind pressure. These forces, which in a vault thrust outward against the walls, are contained within the truss itself because the piece (chord) at the base of the triangle resists by tension the tendency of the two sides to behave like a vault. With its forces in equilibrium, the truss exerts only a direct downward pressure on the walls, so that they need not be thickened or buttressed. This explains why most roofs are triangular in cross section.

In trusses that are too large to be constructed of three members of moderate size, the simple triangle must be replaced by a complex system of smaller triangles within the frame.

Not all peaked roofs are trusses, for in primitive building, in ancient Greece and in much oriental wood architecture the chord is omitted and the sides exert thrust. Nor are all trusses triangular, since the principle may be modified (as in modern steel and heavy timber construction) to apply to arches and vaults if strong enough chords can be found.

7. **Framed Structures.**—A framed structure in any material is one that is made stable by a skeleton that is able to stand by itself as a rigid structure without depending on floors or walls to resist deformation. Materials such as wood, steel and reinforced concrete, which are strong in both tension and compression, make the best members for framing. Masonry skeletons, which cannot be made rigid without walls, are not frames. The heavy timber frame, in which large posts, spaced relatively far apart, support thick floor and roof beams, was the commonest type of construction in the far east and northern Europe from prehistoric times to the mid-19th century. It was supplanted by the American light wood frame, composed of many small and closely spaced members that could be handled easily and assembled quickly by nailing instead of by the slow joinery and dowelling of the past (fig. 14). Construction is similar in the two systems, since they are both based on the post and lintel principle. Posts must rest on a level, waterproof foundation, usually of masonry or concrete, on which the sill (base member) is attached. Each upper story is laid on crossbeams supported on the exterior wall by horizontal members. Interior walls give additional beam support.

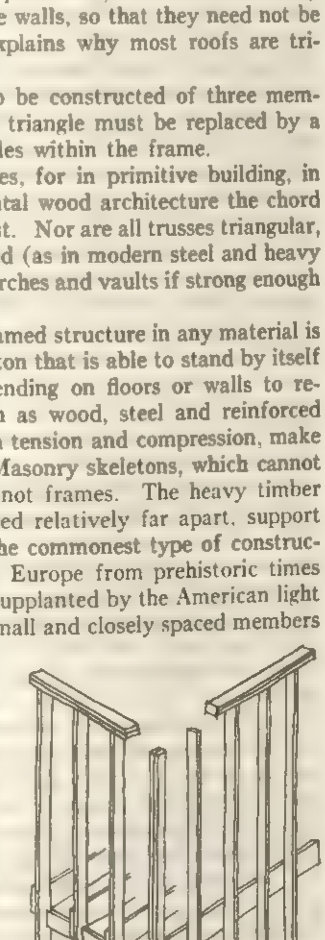

FIG. 14.—FRAMED STRUCTURES
Light wood construction

In the heavy timber system, the beams are strong enough to allow the upper story and roof to project beyond the plane of the ground-floor posts, increasing the space and weather protection. The members are usually exposed on the exterior. In the orient the spaces between are enclosed by light screen walls, and in northern Europe partly by thinner bracing members and partly by boards, panels or (in half-timbered construction) bricks or earth.

The light frame, however, is sheathed with vertical or horizontal boarding or shingling, which is jointed or overlapped for weather protection. Sheathing helps to brace as well as to protect the frame, so the frame is not structurally independent as in steel frame construction. The light frame system has not been significantly improved since its introduction, and it lags behind other modern techniques. Prefabricated panels designed to reduce the growing cost of construction have not been widely adopted. Modern heavy timber and laminated wood techniques, however, provide means of building up compound members for trusses and arches which challenge steel construction for certain large-scale projects in areas where wood is plentiful.

Steel framing is based on the same principles but is much simplified by the far greater strength of the material, which provides more rigidity with fewer members (fig. 15). The load-bearing capacity of steel is adequate for buildings many times higher than those made of other materials. Because the column and beam are fused by riveting or welding, stresses are distributed between them, and both can be longer and lighter than in structures where they work independently as post and lintel. Thus, large cubic spaces can be spanned by four columns and four beams, and buildings of almost any size can be produced by joining cubes in height and width. Since structural steel must be protected from corrosion, the skeleton is either covered by curtain walls or surfaced in concrete or, more rarely, paint. The steel frame is used also in single-story buildings where large spans are required. The simple cube then can be abandoned for covering systems employing arches, trusses and other elements in a limitless variety of forms to suit the functions of the building.

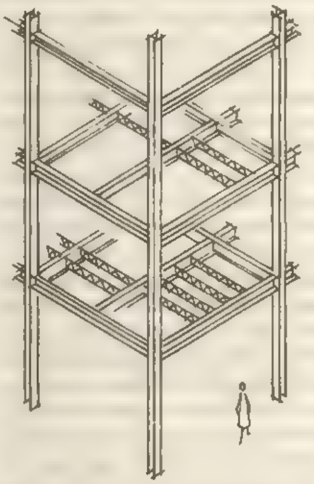

FIG. 15.—FRAMED STRUCTURES
Steel construction

Differences between reinforced-concrete and steel framing are discussed in the section on materials. The greater rigidity and continuity of concrete frames give them more versatility, but steel is favoured for very tall structures for reasons of economy in construction and space. An example is the system called box frame construction, in which each unit is composed of two walls bearing a slab (the other two walls enclosing the unit are nonbearing curtain walls); this type of construction extends the post and lintel principle into three dimensions. Here again, concrete crosses the barriers that separated traditional methods of construction.

III. EXPRESSION

Expression in architecture is the communication of quality and meaning. The social functions and the techniques of building are interpreted and transformed by expression into art, as sounds are made into music and words into literature.

The nature of expression varies with the character of culture in different places and in different times, forming distinct modes or languages of expression which are called styles. Style communicates the outlook of a culture and the concepts of its architects. The boundaries of a style may be national and geographical (Greek, Roman, Mayan) or religious and intellectual, embracing distinct linguistic, racial and national units (Gothic, Buddhist, Renaissance, modern), and different expressions within each of these boundaries are produced by the particular style of regions, towns, groups, architects or craftsmen. The life span of styles may be long (Egyptian, over 3,000 years) or short (baroque, less than 200 years) according to the changeability of cultural patterns. The

principal forces in the creation of a style are tradition, the experience of earlier architecture; influence, the contribution of contemporary expressions outside the immediate cultural environment; and innovation, the creative contribution of the culture and the architect. These forces operate to produce an evolution within every style and ultimately to generate new styles which tend to supplant their predecessors.

The components of expression, which communicate the particular values of style, are content and form. Since content can be communicated only through form, the two are organically united, but here they will be discussed separately in order to distinguish the specific and concrete meaning (content) from the abstract expression of qualities (form).

A. Content

Content is the subject matter of architecture, the element in architectural expression that communicates specific meanings which interpret to society the uses and techniques of buildings.

1. Symbols of Use.—Society requires that architecture not only communicate the aspirations of its institutions but also fulfill their practical needs. Differences in expression, apart from differences in planning, distinguish the forms of architectural types (the house from the church, etc.), the kinds of use (the Catholic from the Protestant church) and the traditions and customs of users (the English from the Swiss Protestant church). When architectural forms become the vehicles of content—in plan, elevation and decoration—they are symbolic. We understand their symbolism, consciously or unconsciously, by association (*e.g.*, spire = church), having seen something like it before, and by the fact that it suggests certain universal experiences (vertical forms "rise"; low roofs "envelop"; we speak of "perfect" circles and squares). We comprehend the meaning of symbols that are new to us, as well as those we know, by association, because the laws of statics restrain builders from putting them into forms so completely unfamiliar that they do not suggest some tradition, just as the structure of language permits endless new meanings but retains a fairly constant vocabulary. The meaning of architectural symbols—or of words—may even change, but the process must be both logical and gradual, for if the change is irrational, the purpose—communication—is lost.

The architectural plan, when used symbolically, communicates through its shape. From prehistoric times and in many cultures, the circle, with its suggestion of the planets and other manifestations of nature, gained a symbolic, mystical significance and was used in the plans of houses, tombs and religious structures. By slow processes it came to be employed for memoria and shrines and for hero cults (such as the pagan Pantheon and Christian martyrs) in both the east and the west. When building techniques permitted, its symbolism often merged with that of the dome. In Hindu temples, the square (and the cross plans developed from it) expressed celestial harmony. The central plan church (circle, polygon, Greek cross, ellipse) fascinated the architects of the Renaissance by its symbolic and traditional values, and it is found in their drawings and treatises to the virtual exclusion of the more practical longitudinal basilicas that they were often commissioned to build.

Plan symbolism remained almost exclusively in the sphere of religion after antiquity, and its traditions gradually disappeared in the course of the 19th century. The modern plan is determined by problems of form (space-mass relationships, etc.) and by the practical demands of use rather than by symbolic communication.

In elevation the most consistent symbolic forms have been the dome, the tower, the stairway, the portal and the colonnade. Domes imply the meanings of the circle and more, since a dome is a covering. Long before masonry domes could be built, the hemisphere was associated with the heavens as a "cosmic canopy," and throughout history domes have been decorated with stars and astrological symbols.

In Rome, Indian Buddhism and Christianity the dome came to mean universal power. In the Renaissance it spread from religious structures to palaces and government buildings, retaining some of its implications of power. In the United States there are few state capitols without domes; the symbol has survived the loss of its original meanings.

The tower, with origins in primitive nature rites, has consistently symbolized power. The Chinese pagoda extends central plan symbolism into towers; many towers and spires rose from the northern Gothic cathedral; and the medieval Italian city was a forest of towers erected by nobles in constant competition to express their supremacy. This meaning survives in our skyscrapers; we boast of their height more than of their efficiency or beauty.

Architectural elements conceived to facilitate the use of buildings may also take on symbolic significance. The stairway, employed in the past to give "monumentality" to important buildings, frequently became more expressive than convenient. Portals, from the time of Egyptian temple pylons and Babylonian city gates, became monuments in themselves, used to communicate a heightened significance to what lay behind them. In the Gothic cathedral they became the richest element of the façade—a translation of biblical doctrine into stone. Since the classic development of the Greek temple, the colonnade on the exterior of buildings has borne similar implications.

Such symbols have become archaic in modern culture and appear as a sign of resistance to new forms. This resistance is especially evident in the popular symbolism of domestic architecture, where the atmosphere of the home is often expressed by cottagelike roofs, shutters, trellises, mullioned windows, grilles and other associations to a more peaceful past.

Decoration, the most easily recognized medium of content, communicates meaning either through architectural elements or through the figural arts (sculpture, painting, mosaic, stained glass, etc.). The architectural elements used decoratively, such as the classical orders, usually originate in technique and in time lose their structural significance to become symbols. In Rome, and from the Renaissance to the 20th century, the formal Grecian orders were applied to buildings of many different techniques as expressions of the continuing influence of Greek institutions. Similarly the new vocabulary of Gothic architecture, developed with new building techniques (the pointed arch, the flying buttress, etc.), became in later periods a source for religious and romantic symbolism. The *art nouveau* of the turn of the 20th century, a system of ornament based on floral and other organic forms, survived for only two decades, perhaps because its symbols were neither drawn from a tradition nor derived from a structural system.

The function of the figural arts in conveying content is a subject outside the scope of this article, but its importance for architecture must be mentioned. The figural arts not only offer the means of expressing more specific ideas than any architectural symbols, but in many styles they define the character of mass and space. The sculptures of the Hindu temple, the mosaics of the Byzantine church and the stuccoes of Moorish palaces are not ornamental applications; they determine the form of the building itself.

The virtual absence of traditional symbols in modern architecture is evidence of the failure of these symbols to express the cultural patterns of the 20th century. In these times architecture, like painting, sculpture and other arts, has tended to be abstract, to emphasize qualities of form rather than the communication of familiar ideas through symbols.

2. Expression of Technique.—The second aspect of content is the communication of the structural significance of materials and methods. Its purpose is to interpret the way in which architecture is put together. The characteristics of materials that are important in expressing design techniques are the properties of their composition (structure, weight, durability) and the way they are used in structure. Their properties may be expressed and interpreted by the treatment of the surface, and their use may be expressed by emphasis on the dimensions and joining of the building units into which they are formed.

The hardness, weight and crystalline composition of stone masonry has traditionally been emphasized by devices not necessarily connected with structural methods: rustication (finishing in rough uneven surfaces), drafting (more refined, linear cutting) and polishing. Niches and other indentations, projecting courses of

frames around openings suggest massiveness. In nonbearing walls, a smooth, unbroken surface implies thinness. The use of stone or brick masonry in construction is emphasized by clarifying the limits of each block, and by the amount of mortar used, and by distinguishing lintels, arches and other specific members from the construction of the wall. The properties of wood are suggested by revealing and emphasizing its texture in load-bearing members and by treating the sheathing of light wood frames in patterns (of shingling or boarding) that communicate thinness. The plasticity of concrete is shown by freedom in modeling and its use in construction by emphasizing the impressions of the wooden forms in which it is cast. The sections of light metal curtain walls are frequently stamped into geometric patterns to illustrate their nonbearing character. Materials that must be covered for protection, such as unfired brick and the steel used in framing, are not adaptable to this type of communication.

At times building methods are demonstrated simply by exposing the structure, as in the heavy timber frame, but in many styles the functions of structural systems have been interpreted by designing their members in forms that are often more explanatory than efficient. The Greek column, which is narrower at its summit than at its base, is diminished by a curve beginning slightly below the midpoint, giving it an effect of an almost muscular power to resist loads. The expression is more explicit in the caryatid, a human figure that replaces the column, and in the burdened animals and dwarfs that support the columns of Romanesque portals. Many elements in the Gothic cathedral serve as diagrams of structure: the supporting piers are clusters of shafts, each of which extends upward without interruption to become the rib of the vault, and the ribs themselves are an elucidation of technique; the flying buttress and the window tracery are elegant interpretations of their functions. In the steel frame building, the hidden forms of the skeleton are often repeated on the façade to enable us to "see through" to the technique, but the system also permits the alternative of expressing the lightness and independence of the curtain wall by sheer surfaces of glass and other materials. The work of the concrete slab is made explicit by projecting indications of the placement of reinforcement or of the distribution of stresses.

The expression of technique is characteristic not of all architectural styles but only of those such as the Gothic and modern in which new techniques excite a search for the interpretive design of their materials and methods. More often than not, both materials and methods have been disguised by decorative forms or surfacing such as veneers, stucco or paint, because of emphasis on the expression of content or of form. Most early stone architecture in Egypt, Greece and India retained as decoration the forms developed in wooden forerunners. The precious marble of Greek temples was disguised under painted stucco; Roman brickwork was hidden by slabs of coloured marble; and 19th-century cast-iron columns were molded into classic or Gothic forms. The history of domes is filled with examples of the successful disguising of method, of giving the ponderous mass the effect of rising from the exterior and of floating from within.

Technical content has been one of the foundation stones of 20th-century architectural theory, particularly in its early phases, and has represented a reaction against 19th-century symbolic content. It is essential for the understanding of modern architecture that the expression of technique be seen as an art—a creative interpretation that heightens awareness of the nature of architecture.

B. Form

In the sphere of use and technique, the architect is responsible to the patterns of his culture on one hand and to the patterns of technology on the other; but in the expression of form, he is free to communicate his own personality and concepts. Not every architect has the gift to exercise this prerogative to the fullest. As in other arts and sciences, a few individuals generate new styles, and others follow, interpreting these styles in original and personal ways. But the majority accepts styles as given and perpetuates them without leaving its mark. The architect's principal responsibility in the formation of style is to create meaningful form. When we speak of form in the arts we mean not only the physical shape, size and mass of a work but also all the elements that contribute to the work's aesthetic structure and composition. Many of these may be without a fixed form of their own—a rest in music, a line in painting, a space in architecture—and gain significance only as they are organized into the finished product. The basic formal elements of architecture in this sense are space and mass. The process of organizing these elements into an ordered form we call composition, and the principal means by which they are given expressive quality are scale, light, texture and colour.

1. Space and Mass.—Space, that immaterial essence which the painter suggests and the sculptor fills, the architect envelops, creating a wholly human and finite environment within the infinite environment of nature. The concept that space can have a quality other than emptiness is difficult to grasp. When we enter a building we see a floor, supports, walls, a ceiling, all of which can be studied and perhaps enjoyed, while the space, in the sense that we are accustomed to think of it, is void: the absence of mass, filled by air.

But spatial experiences that express something are common to everyone, though they are not always consciously grasped. We feel insecure in a low cave or a narrow defile, exhilarated and powerful on a hilltop; these are psychological and motor reactions that result from measuring our potential for movement against the spaces that surround us, and the same reactions take root even in our language (we speak of "confining" circumstances, "elevating" experiences). An infinite variety of such reactions may be summoned by the architect, because he controls the limits above, below and on all sides of us. As we enter his space we measure it in terms of the degree and the quality of our potential for movement. The concept of potentiality is important, first, because we can anticipate where we may move by merely looking about us, and, second, because we can conceive movements that we cannot execute. So, in the nave of a Gothic cathedral, the high walls closely confining us on two sides restrict our possible movements, suggesting advance along the free space of the nave toward the altar; or their compression forces us to look upward to the vaults and the light far overhead, and there we feel a physical sense of release, though we are earthbound. We call the experience of Gothic space "uplifting" because it urges us to rise.

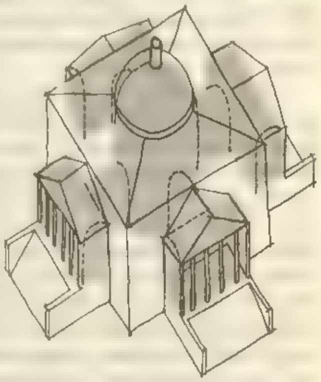

FIG. 16.—SPACE AND MASS

Diagram showing the interior (space) and exterior (mass) of the Villa Rotonda, Vicenza, Italy, by A. Palladio, 16th century

Renaissance space, on the other hand, attempts to balance its suggestion of movement, to draw us to a focal point at which we can sense an equilibrium of movement in all directions, a resolution of the conflict of compression and release (fig. 16). At this point we feel physically at rest, at the opposite extreme from the elevating sensation of the cathedral.

Of course, we do not use our eyes alone to feel spatial quality, because only the simplest spaces—a cubic room, for example—can be wholly experienced from one standpoint. In a complex of spaces, like that of the cathedral, we walk about, gaining new sensations, seeing new potentials for movement at every step. Most modern architecture, in its free organization of space sequences, demands mobility; its techniques have made it possible to remove the heavy walls and supports of the past, reducing the sense of compression. Walls become membranes to be arranged at will for spatial experience, and some are transparent and so extend our potential for movement into the limitless out-of-doors.

Spatial experience is not restricted to the interiors of buildings. The sensations we have in nature's open spaces may be re-created by art. City squares and streets, even gardens, achieve a variety of expression comparable with that of interiors. The

baroque piazza of St. Peter's in Rome, which directs us along its great embracing arcs toward the entrance, is at least as moving as the church interior. Wherever buildings limit or direct our vista we are in an architectural environment, an outdoor room.

The exterior of a single building, particularly one that is isolated from other architecture, does not create a space. It occupies the space of nature. Thus, it may be experienced as sculpture, in terms of the play of masses in a void. The aesthetics of masses, like that of spaces, is rooted in our psychology. When we call a tall tree or a mountain "majestic," a rocky cliff "menacing," we are projecting onto them attributes that are ours, not theirs. We inevitably humanize inert matter and so give the architect the opportunity to arouse predictable patterns of experience which are universal.

The appreciation of mass, like that of space, depends on movement, but this movement must be physical. It cannot be experienced in anticipation because no matter where we stand to observe even the simplest building, part of it is out of sight. The mass of a complex building is differently composed from every point of view. The critic Sigfried Giedion, emphasizing the need for movement in experiencing modern architecture, suggested that architecture may be four-dimensional, since time (for movement) is as meaningful as the spatial dimensions.

Some architecture depends much more on mass expression than on space expression. The Egyptian pyramid and the Indian stupa have no meaningful interior spaces; they are architectural in function and technique, sculptural in expression. The interior of a Greek temple is of little interest compared with the wonderful play of forms on its colonnaded exterior, while early Christian and Byzantine architecture reverse the emphasis, making the simple exterior a shell for a splendid and mystical space. Gothic architecture balances the two, partly in order to express a dual content: earthly power over the world outside, spiritual power inside. Modern techniques permit a reduction of the contrast between space and mass expressions by reducing the mass of walls and the size and number of supports and by allowing the interpenetration of interior and exterior space.

2. Composition.—Space and mass are the raw materials of architectural form; from them the architect creates an ordered expression through the process of composition. Composition is the organization of the whole out of its parts—the conception of single elements, the interrelating of these elements and the relating of them to the total form.

The simplest architectural element is a plane, the flat, two-dimensional surface that limits masses and spaces. The simplest plane is a rectangular one without openings or decoration—the wall of a room, for example. This wall is given quality solely by the proportion of its width to its height. Now a door is put into the wall; the door itself has a certain proportion, and a third element is injected, the relation of two proportions. A window is added, and the composition becomes more complex; then a row of windows, and sequence becomes a factor in addition to proportion and relation. Sequence again involves the concept of motion; we say of the row of windows that it "runs along" the façade or that it is "rhythmically" designed.

Finally, our wall may gain rich subleties of composition within its proportions and rhythms. It can be modeled—into a complex of planes, irregular or curved surfaces—to provide the dimension of depth to its proportions; or symbols of use or of technique can become part of its expressive form.

No architectural planes stand alone, of course; they always intersect other planes. Our room wall meets two other walls, the floor and the ceiling, and a façade wall meets the ground, the roof and two other walls. So the total composition of this wall must be harmonized with the composition of other planes in a three-dimensional whole.

The means of achieving this harmony differ in every style. Greek architects developed a system of proportions based on the lower diameter of the temple column, from which spatial intervals and the measurement of masses were derived by multiplication and division. Medieval architects first used arithmetical modules based on the measurements of areas in the cathedral plan, and in the Gothic period changed to a geometric system that employed chiefly the equilateral triangle and the square, figures which had a symbolic and mystical value. In Renaissance theory, proportions and harmonies were developed from systems of musical composition, since architects believed that relationships in all the arts depended on an all-pervading celestial harmony. Several modular and proportional systems have been evolved by modern architects (*e.g.*, Le Corbusier's "Modulor"), but none has been widely adopted.

Behind these changing theoretical methods, however, there seems to be a constant human reaction to spatial relationships that distinguishes harmony from cacophony, that makes us bored with a perfectly cubic room, or prefer certain rectangular forms to others. This psychological response to form probably is connected to our mechanisms of balance, our movements and stature—in short, to our own composition—but the scientific analysis of the process is still at an early stage of development.

Some buildings have only a single, simple interior space (the Pantheon in Rome) or exterior mass (the pyramids of Egypt) and are not less expressive on this account. But composition carries on into a richer dimension as soon as two or more spaces or masses are organized into the whole. Such a complex composition must give a co-ordinated form to connecting spaces and masses, each of them in itself a unique harmony. We must be made to feel, in moving through the spaces and around the masses, not only that each is related to the one that precedes and follows it but that every one is contributing to a concept of the whole: a form that is greater than the sum of its parts. In the Gothic cathedral the nave, the aisles alongside it, the transept that crosses it toward one end, the choir and apse beyond, may each be experienced separately for its own quality. But the experience gains its full meaning only when the form of the total expression is realized: the low aisles giving grandeur to the high nave, the three together leading to the confluence of the two transept arms at the crossing in a vast climax that prepares for the resolution or finale at the altar. In the same way, the significance of a total mass composition unfolds as we move about its separate parts. At St. Peter's in Rome, the three projecting apses are gathered into a unity by the undulating walls; they prepare for the cylindrical drum, the drum for the dome, the form of which leads to the culminating lantern, which is harmonized with the drum. Toward the façade, two little domes frame and prophesy the great one, as the cathedral aisles do the nave. While these particular examples from the past illustrate symmetrical compositions with a climax, others of equal quality might be chosen to show irregular unity that is no less expressive (the Erechtheum in Athens; Mont St. Michel abbey in France).

In modern architecture, as in modern painting, Renaissance laws of composition, which emphasized the symmetry and balance of semi-independent units, have been supplanted by principles that imply the continuity of the whole and remove distinctions between parts. The biological term "organic" is sometimes used to describe a process of composition that seeks to develop interdependent spaces and masses that function expressively as members of an organism.

If composition were merely a matter of organizing a certain number of relationships, the process would be mechanical, not creative, and all architecture would be equally good, or, more likely, bad. The purpose of composition is to express particular concepts and experiences, and it is successful only when these are fully communicated to the observer.

3. Scale.—When the proportions of architectural composition are applied to a particular building the two-termed relationship of the parts to the whole must be harmonized with a third term—the observer. He sees not only the proportions of a door and the relationship to those of a wall (as he would in a drawing of the building), but he measures them against his own dimensions. This three-termed relationship is called scale.

A well-scaled building such as a Greek temple will serve for illustration. If it were to be magnified to the size of St. Peter's in Rome, with its proportions remaining unchanged in their own relationships, the temple would be out of scale with us, and the

result would appear monstrous. If the columns were to be doubled in width while the temple remained the same size, they would be out of scale with us and out of proportion with the whole. We can understand what makes the proportions of the temple satisfactory as they are, because they are based on certain aesthetic principles established by the Greeks, principles that are partly rooted in our psychological make-up and partly accepted by custom, like musical consonances. But it is more difficult to understand why their scale is successful within a certain range of size, for neither the Greeks nor anyone else established laws to relate scale to size. They found their solution by experiment and subjective judgment.

It may be that the success of scale depends upon our ability to comprehend proportions in relation to some unit or module that is roughly man-sized and close enough to us in a building to permit us to measure it against ourselves. The Greeks, in employing the base of the column as a module for all the proportions of a temple, give us a unit of a size that we can grasp easily, and one that is close to eye level as we approach the temple. This module is a key to relationships among elements too far away to measure. This can be done in much larger buildings, too, where the elements close to us are too massive to be measured easily. Roman and Renaissance architecture retained the Greek orders as decoration partly for this reason, using them to break up huge masses into more comprehensible parts. In entirely different styles of architecture, such as the Gothic, where the expressive function requires immeasurable proportions, we are still given a measurable module in the base of the pier. But piers and columns are not always a source of the module. In masonry construction, the single block can serve the same purpose. In frame construction, the bay (distance between floors or columns) or doors and windows may make a better key. The most successful modern skyscrapers retain a comprehensible scale, in spite of their size, by the repetition of some such module, and this is one reason why the skeleton is so often expressed on the exterior even when it is hidden behind walls.

4. Light.—We think of light as that which makes it possible for us to see: a necessity and, in architecture, a utility. But light is also a powerful, though ephemeral, vehicle of expression. Because it moves, changes character, comes and goes with its source, light has the power to give to the inert mass of architecture the living quality of nature. The architect, though he does not quite control it, can predict its behaviour well enough to catch its movements meaningfully. He channels it through openings into his spaces and molds it on the surfaces of his masses by changes of plane, making it enliven his forms by contrast with shadow.

The sunlight that falls on the exteriors of buildings cannot be directed or changed in quality, but it can be reflected or absorbed in a wide range of modulation by the relief and texture of surfaces. So the planes and decoration of a façade are not just the lines the architect makes on his working drawings but receptacles of light and shadow that change in character, even in form, as the earth moves about the sun.

Because of this link between nature and art, an important part in the formation of local architectural styles is played by the variation in the quality and intensity of light in different climatic regions.

The architect controls interior light better than exterior light since he can select the position, size and shape of its source. With glass and other transparent materials he transforms even its colour and intensity and so gives light a new meaning independent of that which it imparts to the structure. We realize this most powerfully in the Gothic cathedral, where the stained glass windows transform the rays of the sun into a mystical diffusion that descends on us from above like a supernatural vision.

Furthermore, light may be illusory, dissolving rather than clarifying form. When it comes to us out of darkness in great intensity it seems to spread outward from its architectural channel. This illusion may be employed to express meanings, as at Hagia Sophia in Istanbul, where the light from the base of the dome hides the supports, giving the impression that the whole massive canopy floats on air.

5. Texture.—Texture plays a dual role in architecture: it expresses something of the quality of materials and it gives a particular quality to light. Although we absorb both qualities simultaneously by eye, the first has tactile, the second visual associations.

Specific tactile textures are peculiar to every material by virtue of its manufacture or natural composition, but they may be altered to produce a variety of expressive qualities. Any stone may be used in its natural, irregular state, it may be chiseled in a rough or smooth texture or highly polished, to convey a range of meanings from vigour to refinement.

Visual textures are produced by the patterns given to the lighting of the surface both through the way the materials are worked (vertical or horizontal chiseling of stone, a carved frieze) and through the way they are employed in building (vertical or horizontal boarding, projection and recession of courses of brick). Like all patterns, visual textures create associations of movement, giving rhythm to the surface.

A single texture is rarely employed in building. The variety of materials and treatments typically produces a complex of textures that must be composed and harmonized like the forms and spaces of architecture into a consistent expressive whole.

6. Colour.—Since colour is a characteristic of all building materials it is a constant feature of architecture. But building materials are selected primarily for their structural value, and their colours are not always suited to expressive requirements. So other materials chosen for their colour are frequently added to the surface. These include pigments, which usually preserve the texture of the original surface, and veneers of stone, wood and a variety of manufactured products that entirely alter the surface character.

But colour, regardless of how it is produced, is the most impermanent element in architecture. It changes with the weathering and staining of materials (the white Gothic cathedrals are now deep gray) or, if it is superficial, it can easily be altered or removed (as the coloured stucco veneers of Greek temples or the bright marble facing on Roman brickwork).

The values that we associate with colour (we call yellow and red "gay," black and deep blue "sombre") are independent of materials and forms, and they give the architect a range of expression not provided by other means at his disposal. A different expressive device is provided by the great range of light reflection in the colour scale. Colours that reflect light brilliantly appear to advance and those that absorb light to recede. So the degree of projection and recession of architectural forms may be altered, emphasized or subdued by the colours of their surfaces.

Architecture, unlike most of the other arts, is not often conceived independently of particular surroundings. The problems of design extend beyond the organizing of space and mass complexes to include the relating of the total form to its natural and architectural environment.

In site planning, a primary function of architectural design, the architect aims to create harmonies with pre-existing elements in the landscape and "townscape."

But the province of the architect is not limited to the conception of single structures in harmony with a given setting. Throughout history architects have been employed in giving a new form to the environment itself: planning the natural surroundings by the design of parks, roadways, waterways, etc.; designing complexes of related buildings; and organizing the urban environment into areas of residence, recreation, assembly, commerce, etc., both to increase their utility and to give them unique expressive qualities through the interrelationship of groups of buildings to the open areas about them.

For a résumé of articles dealing with specific subjects in this field, *see* ARCHITECTURE (ARTICLES ON).

BIBLIOGRAPHY.—The following list includes works of general importance; bibliographies for special periods and styles may be found under separate articles (*e.g.*, GOTHIC ARCHITECTURE; RENAISSANCE ARCHITECTURE; etc.) and in volumes of *The Pelican History of Art* (1954–).

General: Vitruvius, *De architectura;* Leone Battista Alberti, *De re aedificatoria* (1485); Andrea Palladio, *I Quattro libri dell' architettura*

(1570); E. E. Viollet-le-Duc, *Dictionnaire raisonné de l'architecture française* (1854–68); *Wasmuths Lexikon der Baukunst* (1929–32); Julius Schlosser-Magnino, *La letteratura artistica*, with bibliography of architectural theory (1935).

Use: Julien Guadet, *Éléments et théorie de l'architecture* (1901–04); Lewis Mumford, *The Culture of Cities* (1938); James M. Fitch, Jr., *American Building* (1948); Sigfried Giedion, *Mechanization Takes Command* (1948); Talbot F. Hamlin (ed.), *Forms and Functions of Twentieth-Century Architecture* (1952); Robert W. Kennedy, *The House and the Art of Its Design* (1953).

Technique: Martin S Briggs, *A Short History of the Building Crafts* (1925); P. Brandt, *Schaffende Arbeit und bildende Kunst* (1927); Lewis Mumford, *Technics and Civilization* (1934); F. E. Kidder and Harry Parker, *Architect's and Builder's Handbook* (1936); Charles M. Gay and Harry Parker, *Materials and Methods of Architectural Construction*, 2nd ed. (1943); Eric de Maré (ed.), *New Ways of Building*, rev. ed. (1951); Leonard Michaels, *Contemporary Structure in Architecture* (1950); Louis Francis Salzman, *Building in England Down to 1540* (1952).

Expression: John Ruskin, *The Seven Lamps of Architecture* (1849); E. E. Viollet-le-Duc, *Entretiens sur l'architecture* (1863–72); Geoffrey Scott, *The Architecture of Humanism* (1914); Lewis Mumford, *Sticks and Stones* (1924); Le Corbusier, *Towards a New Architecture* (1927); Frank Lloyd Wright, *Modern Architecture* (1931); John Summerson, *Heavenly Mansions* (1949); E. Baldwin Smith, *The Dome: a Study in the History of Ideas* (1950); M. Borissavliévitch, *Les théories de l'architecture* (1951); Rudolf Wittkower, *Architectural Principles in the Age of Humanism* (1950); Meyer Schapiro, "Style," in *Anthropology Today* (1953); Bruno Zevi, *Saper vedere l'architettura* (1953); Sigfried Giedion, *Space, Time and Architecture*, 3rd ed. (1954); Earl Baldwin Smith, *Architectural Symbolism of Imperial Rome and the Middle Ages* (1956). (J. S. A.)

ARCHIVES. The term archives designates the organized body of records produced or received by a public, semipublic, institutional, business or private entity in the transaction of its affairs and preserved by it, its successors or authorized repository through extension of its original meaning as the repository for such materials. The terms records and record office are used in the United Kingdom and in some parts of the British commonwealth.

Although the institution of archives and something of archival administration may be traced from antiquity, as they are understood today they date from the French Revolution. With the establishment of the Archives Nationales in 1789 and of the Archives Départementales in 1796, there was for the first time a unified administration of archives which embraced all extant repositories and record-producing public agencies. The second result was the implicit acknowledgment that the state was responsible for the care of its documentary heritage. The third result was the principle of accessibility of archives to the public. It was not until 1840, however, that the basic canon of modern practice, *respect pour les fonds*, was developed in France and Belgium and subsequently refined by the Dutch and Prussians to include stability within the *fonds*.

HISTORY

Antiquity.—It is generally agreed that archives have been in existence among oriental peoples and among the Greeks and Romans since the written word came into common use. Archives are known among the Hittites, Assyrians, Medes, Persians, Babylonians and Egyptians. It is important to remember, however, that the survival of records clearly archival in nature does not by itself establish the existence of archives as an institution.

There is no evidence of archives among the early Greeks. The first regular archives, at least for the originals of laws, is usually considered to have been founded by the Athenian general and statesman Ephialtes about 460 B.C., but it was not for another 100 years that Athenian public records were centralized in a single place, the temple of the Mother of the Gods (the Metroon). This choice of a religious edifice, as a place providing both physical security and sanctity, recurs in the middle ages, when the records of secular authorities were often safeguarded in monasteries. In the Metroon were deposited laws, decrees, reports of meetings of the senate and of the people, decisions of the criminal courts, financial records and copies of decisions taken by the highest magistrates of the state. Exceptional private documents occasionally found a place there also. It is highly probable, although the evidence is not conclusive, that other cities had their archives too. The oracle at Delphi possessed an archive of earlier pronouncements.

In the strict sense it was only the original or the draft of a document that went into the archive. The public, or published, version inscribed on some durable substance was a copy, and it is therefore erroneous to assume that the temples or other public places in which these were displayed were archives. Government agencies held their own records but eventually transferred them to the archives. These originals they could borrow again for official use; private citizens could get copies. The formal responsibility for the safekeeping of the archives was given to various officials at various times, but the actual work was performed by a staff of archivists and clerks.

Much more is known of Roman archival practices than of Greek. In the earliest times records were kept in the house of the king, subsequently in the houses of the consuls, but by the 5th century B.C. they had been transferred for reasons of security to a public building. The main archive, established by the statesman Valerius Publicola (fl. 509 B.C.), was in the aerarium, or treasury, of the temple of Saturn. There were housed national laws and decrees, the acts of the senate, the censors' lists, reports of officials from senatorial provinces and financial records. International documents were housed in the Capitol.

Even during the republic there were a number of other archives in Rome, under various officials, and in the empire there was created the *tabularium Caesaris*, or archive of the emperor, wherein were housed not only the personal papers of the imperial household but also official records. In this latter period archives existed throughout the empire. There were municipal archives in which were deposited annually the acts of the municipal councils, the financial records, records of births, adoptions, property and similar matters of concern to individuals. Provincial archives contained in addition to the usual administrative records, records of land, censuses, contracts and births. There were military archives in each camp, and each priestly college had its records.

Toward the end of the republic archives were but poorly safeguarded and the early emperors gave much attention to restoring faith to public records. The code of Justinian I (A.D. 529) has a section on archives and archivists. The archives, administered by career officials and their clerks, were usually arranged by series in a chronological order and numbered. Certified copies could be obtained and records were used by researchers.

Middle Ages and Early Modern Period.—In the west the archives of the bishops and popes of the Christian church formed a bridge from antiquity to the middle ages in archival practice. In Byzantium, because of the static situation, there was some secular continuation of Roman archival organization, whereas in the west the mobile court of the rulers made this impossible. The *archiva viatoria*, or mobile archives, found from the 12th century, necessarily were limited to the minimum essentials and undoubtedly contributed to the destruction rather than the preservation of masses of documents. At least from the 10th or 11th century onward the powerful secular figures put their papers in ecclesiastical archives and what has survived is largely the result of this practice.

There were papal archives before there was a papal archival repository. There is some doubt about the references to an archive established in the late 4th century, but none about that of the mid-6th century. Pope Paul V is the founder of the privy Vatican archives in the first years of the 17th century. Numerous church archives date from the 8th and 9th centuries. The *gesta municipalia* of the Roman empire were continued in France and Italy under the name of *archivum curiae*, until the 9th and 10th centuries respectively. In Germany the cities followed upon the organization of the church and are, therefore, not directly related to the ancient practices. Venice and some other Italian cities had archives dating from the 11th century and by the end of the 13th century Florence, for example, had a statute on the regulation of the public archives.

There is reference to a royal archive in England from the 9th century, but this (if it existed) probably formed part of the treasury and had no fixed location. In any case, the oldest series in the archives of the exchequer dates from 1130. In 1323 the

first inventory in England was completed. This was regarded as a model of its kind by contemporary archivists, and it served as the pattern for the inventory prepared 25 years later for the Trésor des chartes in France which had been founded by Philip the Fair. The emperor Maximilian I attempted to set up a central archive for the Holy Roman empire, but without success. In 1543 the archives of the crown of Castille were founded at Simancas by Charles V. The growing concern for archives in the 17th century is manifested by the appearance of numerous handbooks on archival administration. The archives of the Austrian dynasty and empire, the Haus-, Hof- und Staatsarchiv, were not founded until 1749. The Archivo de Indias was created in Seville in 1785. The scheme of Napoleon I to establish a central archive of Europe at Paris did not succeed.

EUROPE

The British Isles.—The English Public Record act of 1838 brought all separate collections together and placed them under the master of the rolls. England, therefore, is the outstanding example of centralization, whereas the more usual practice is decentralization of archives to the domestic area in which they originated. By an order of 1854 the basic authority was extended, with the result that the public record office now houses two main divisions of archives, judicial and state papers, with the second including the records of ministries and similar agencies which have ceased to serve administrative needs. In these collections are intermingled many documents not strictly of a public nature, and outside them are many collections of vast importance which, though strictly public, were by the laxities of earlier days retained in private hands. The problem of securing the papers of retiring public officials is one which, in spite of enabling legislation, still plagues archivists of all lands. The second quarter of the 20th century brought a greatly increased awareness of local records, with the result that county record offices are widespread, records have been given intelligent shelter by libraries and private papers have been the object of organized public concern. On the national level, following World War II, elimination of records claimed much attention, as did storage in intermediate repositories, the revision of the *Guide* to the public record office and the continued preparation of lists; and, more particularly, the National Register of Archives (1945), the primary purpose of which is the discovery of location and extent of all archival collections in England except those of the central government; and the work of the Historical Manuscripts commission which started its studies in the 19th century. Publication was extensive on all levels. In Scotland the principal collection of public records has been assembled in the General Register house (1784), which, like many another repository, is full to overflowing. Many essential records, of course, are to be found in England, as is true also with respect to Ireland, whose public record office (1867) was seriously damaged in 1922.

The Continent.—Practice and principle have varied somewhat in the several countries, but the pattern has been a central repository and, if conditions warrant them, provincial repositories. France has kept in the departmental archives not only the modern archives relating to the area but also those from the prerevolutionary period. The Netherlands has a central state archives and the provincial archives. The former state of Prussia maintained not only its privy state archives in Berlin but also repositories for records of the central administration which were kept in the areas to which they pertained. The other sovereign states, such as Bavaria, Württemberg and Baden, each maintained their own central (and sometimes area) archives. The Reichsarchiv at Potsdam dated only from 1919. The schism following World War II gave the Federal Republic of Germany a Bundesarchiv at Coblenz and the German Democratic Republic a central archive at Potsdam. In Switzerland the treasures for research are found in the archives of each of the cantons rather than in the Bundesarchiv (1798) at Berne. Italy has no single, central institution for state archives, but has a series of important repositories, united under the ministry of the interior, which reflect the earlier divisions of the country. The modern Vatican city has within its confines some of the oldest extant archives, dating from the 4th century. Legislation in most European countries with highly organized central governments has given the central archives the right to inspect other archives. In Germany there has been, in addition, the system of honorary curatorships of local archives as means of safeguarding such materials. Wars have wreaked havoc with archives and have presented problems to archivists. Many modern states have their origins tied with other states in whose archives have reposed vital records in many cases inextricable, in others subject to transfer in accord with treaty agreements, in others procurable through microcopy. Much has been written on the fate of archives as the result of World War II, but in no single source is it possible to get the composite story. Archives have been destroyed (Naples), passed from original sovereignty (free city of Danzig), sequestered for a period by occupying powers (German foreign office) or confiscated (Nazi party records). Later, the state archives of Florence were gravely damaged by flood in 1966.

NORTH AND SOUTH AMERICA

United States.—The national archives was established in 1934 to house the retired records of the national government. In 1952, when the Declaration of Independence, the constitution and the records of the continental congress were transferred from the Library of Congress, the building contained roughly 800,000 cu.ft. of records. The responsibilities and authority of the national archives were considerably extended by law in 1949, especially by the Federal Records act of 1950 which authorized the archivist to survey government records, records management and disposal practices; to promote improved records practices and controls including the creation, organization, maintenance, use and ultimate disposal of current records; and to establish and operate centralized intermediate records repositories. By the end of 1952 federal records centres had been established in eight of the ten regions into which the country had been divided by the General Services administration, and in two years time had received 1,400,000 cu.ft. of records and had released expensive space and filing equipment worth $5,400,000. A convenient yardstick by which to measure the growth of modern record making is the considered estimate that in the department of the army the period from the establishment of the national government to the start of World War I (1789–1917) had produced 20% and the period 1917–19 had produced 80% of the records. Under the federal system of government each of the states independently has its own archival agency established in various forms and operating in various ways. Recommendations toward uniform archival legislation and practices had not met with success by the middle of the century. The tremendous mass of county and municipal archives first came under adequate control as the result of the operations of the Historical Records survey (1936–43), which likewise had inventoried large numbers of church archives and had prepared guides to collections of historical manuscripts. Work on the National Union Catalog of Manuscript collections started in April 1959. In common with other countries in the Americas the United States has its archival roots in Europe, and early in the 20th century the Carnegie institution of Washington sponsored a series of *Guides to the Materials for American History* in many countries.

Canada and Latin America.—The public archives of Canada (1872) have extensive holdings of original materials which in the middle of the 20th century were being supplemented through long-term copying programs of pertinent Canadiana found in the public record office in London and elsewhere. The provinces maintain their own archives. Throughout the country the usual archival problems had arisen, and considerable attention was given to control and administration. The archives of almost all the 20 Latin-American republics have as their bases the records of the colonial government prior to independence. This relates them intimately with the archives of European (especially of the former parent) countries. Like many of their counterparts in Europe, the archival institutions (a number of which are at the century mark) often have been housed in former palaces or other structures not originally intended for the storage and exploitation of archives. Climate has been a variable factor. In Brazil, for example, the hot humid air of Rio de Janeiro is one of the reasons why many of

the colonial records no longer exist. In Chile, on the other hand, the climate has been favourable, and for this and other reasons the colonial period is well represented in the archives. Panamá, the newest of the republics (1903), was the first (1924) to erect a building intended expressly as a national archive; it was established in 1912. Colombia was among the countries which early provided for the elimination of useless archives. El Salvador was the only one of the Latin-American countries which had not, by the early 1960s, established a national archive. Many of the records of the colonial period still remained in Guatemala, although some had been turned over to El Salvador. Cuba, which did not win its independence from the European parent country till 1899, owed the foundation of its national archive to the Spanish period of its history. Because of the climate and removals of entire collections at the close of the Spanish regime, few archives in Cuba antedate 1800. Probably the largest collection of colonial archives in Latin America survived in Mexico.

AFRICA, ASIA AND AUSTRALASIA

These areas were distinguished by new developments in the mid-20th century. The Union of South Africa, which maintains a central archives and a repository in each state, was engaged in extensive microfilming projects for assembling south Africana in Europe and North America. The central African archives at Salisbury, Southern Rhodesia, created in 1935, necessarily confined its activities largely to planning and organization until after World War II, but then also embarked upon microcopying projects. The archival service of the Republic of the Congo was established in 1947 with photocopying equipment and a documentation centre. Israel had established a national archives and from 1933 was the locale of the Zionist central archives which was founded in Berlin in 1919. India and Pakistan each had established a national archives; each shared the problems of a new sovereign state in tracking down records; each had its administrative roots in a century or more of British records. Pakistan had the added problem of copying in the Indian national archives those records which bore directly upon its history but which could not be separated from those relating also to India. India had the problem posed by the imperial record department. The archives of the Republic of the Philippines suffered severely as the result of World War II, but subsequently efforts were made to rehabilitate these records and to preserve a considerable quantity on microfilm. Archival administration in Australia, which really came into being only at the start of World War II, was complicated by the fact that not only had many of the states prior to the establishment of the commonwealth in 1901 performed functions normally reserved to a national government, but subsequently had continued those functions for several decades; that libraries (in the absence of archives) had taken over public records; and that the principle of provenance had been but imperfectly followed in earlier activities. Japan had no national archives or archival administration. Those records, still in the custody of the ministries, which had survived the earthquake and fire of 1923 suffered severely as the result of the bombings of Tokyo during World War II. A considerable number of the archives of the foreign office were microfilmed (about 2,200 reels of 100 ft. each), and the films were available at the Library of Congress in the United States.

INTERNATIONAL ARCHIVES

The records of international governmental organizations which have continued in being or which have been succeeded directly have presented no problem. Records of defunct agencies such as the International Refugee organization (IRO) and the United Nations Relief and Rehabilitation administration (UNRRA) have been provided for through the fortuitous existence of the United Nations and its archival administration. The records of the many hundreds of international governmental conferences and of professional congresses which have not been sponsored by continuing organizations usually have been given shelter by the host country.

MANAGEMENT

Records Control.—Three elements are essential to archival control of modern records: (1) the determination of types of records to be removed from agency of origin; (2) the time of disposition; and (3) the manner of disposition. Practice has varied, but elimination usually has occurred before records have been transferred from the agency of origin. Some countries, especially those whose history reaches back many centuries, have prohibited the elimination of records made before a specified date. Regular schedules which provide (in accord with the laws of the country, the needs of administration and historical values) for regular movement by type of record with a view to elimination, temporary storage in an intermediate records centre or permanent preservation in an archival repository have come into rather general use.

Technology and Special Types of Records.—The inventiveness of man has brought newer problems as it has solved older ones. Archivists had to add specialization in photographic records, motion pictures, sound recordings and kinescopes. They turned, albeit only slowly, to conversion of their papers to film. Microfilm, the legal status of which as record copy usually has had to be determined by special legislation, is a practical medium for making additional copies of records as security against risk through acts of warfare; as preservation against normal deterioration or damage; for use in international exchange; in lieu of loan or as a convenience to scholars; for reducing costs of repair, binding (or its equivalent) and storage; as a means of supplementing by collateral materials the main bodies of records; and as a form of publication. Practice as well as belief varied from country to country. As the concepts of social, economic and cultural history developed, as industrialization played an increasingly prominent role in national and international affairs, as democratization spread over the surface of the globe, so there was an increasing awareness of the significance of business archives, institutional archives and the papers of persons not necessarily distinguished. Germany was the first to recognize the value of business archives; Belgium, Switzerland and the Netherlands followed shortly; France, England, Denmark and the United States are examples, in varying degree and nature, of later recognition.

Protection.—National and international measures, especially in time of war, have been devoted to the protection of archives. Notable in modern times are the annexes to The Hague convention of 1907, the Roerich pact signed in 1935 by countries of the Americas, and the convention drafted by the United Nations Educational, Scientific and Cultural organization (UNESCO) in 1950–53. UNESCO likewise prepared a manual for the protection of cultural properties in peace or war which superseded the one motivated by the civil war in Spain in 1936. During World War II neutrals and belligerents alike took passive measures of defense with greatly varying degrees of success. Although some entire collections of archives were wiped out, some *fonds* in larger institutions destroyed or otherwise lost and countless archival structures damaged or destroyed, the losses (so far as the political events subsequent to the termination of hostilities permitted assessment) were less than might have been expected in total war and postwar reconstruction. The Allied armies, notably the British and the United States, organized the Monuments, Fine Arts and Archives service, published numerous lists and directories of cultural buildings and materials which were to be respected, issued cultural maps to the air forces in an attempt to safeguard these from attack and did what they could to preserve that which they found in dire need. During the occupation of Germany each of the western Allies continued the Monuments, Fine Arts and Archives service not only as the medium for restitution of looted art and archives but as that for rehabilitation. At an earlier date the Monuments, Fine Arts and Archives personnel in the Allied commission for Italy had performed the same services.

PROFESSIONAL DEVELOPMENT

Schools.—Although there had been a chair of archival science at the University of Mainz as early as 1790, modern specialized training of archivists may be said to begin with the establishment in 1821 of the École Nationale des Chartes in Paris, the first of the three internationally famous schools. The Institut für österreichische Geschichtsforschung was founded in Vienna in 1854, and

the Institut für Archivwissenschaft und Geschichtswissenschaftliche Fortbildung was organized in its final form at Berlin-Dahlem in 1930. This last was revived in 1949 at the state archives in Marburg. Czechoslovakia opened its school in Prague in 1923, the U.S.S.R. started its school in 1938, and formal training in the United States dates from the same year. After World War II the trend was toward school training. The Dutch and Bavarian schools were revived and the English, long the distinguished proponents of direct appointments, developed university courses for archivists. Curriculums were varied but, except in the United States where problems arose almost entirely from modern records, they regularly included not only history, administration and methodology but also paleography, diplomatics, sphragistics, chronology and languages. Modern records problems led to the creation of new techniques and to the need to propagate those techniques through instruction such as that given not only in the United States in courses on records management and archival administration but also in the stages techniques, lectures and laboratory exercises established in Paris by the Direction des Archives de France, the purpose of which was to provide the traditionally trained archivist with the understanding which would enable him to cope with the avalanche always about to slide upon his institution.

Literature.—In common with many subject fields, archival administration is less documented by basic texts than by periodical literature. The Dutch produced the first modern treatise, entitled *Handleiding voor het Ordenen en Beschrijven van Archieven,* in 1898, and this filled so obvious a lacuna that it was translated into German (1905), Italian (1908), French (1910) and subsequently, from the second edition, into English (1940). *Archivistica,* by Eugenio Casanova, had never been translated although, in many ways, its second edition (1928) was the most complete general text on the subject. Sir Hilary Jenkinson treated the subject in his *Manual of Archive Administration* (1937) in a manner generally different from that of his continental colleagues. Adolf Brenneke in his *Archivkunde: ein Beitrag zur Theorie und Geschichte des europäischen Archivwesens* (1953) devotes four-fifths of the book to the historical development of archives and archival practices in many countries outside as well as in Europe. The Spanish-speaking world produced a number of manuals, many of which were of local application. *Modern Archives: Principles and Techniques* (1956) by Theodore R. Schellenberg already has been translated into several foreign languages. Of historical interest is the treatise *De archivis* (1632) by Baldassarre Bonifacio (who was a bishop, lawyer, college president and *littérateur* extraordinary, but not an archivist by profession), as are the works of the Württemberger Jakob von Rammingen, who set forth his practical ideas on the importance of archives, the duties of the archivist and the arrangement of archives in 1571. Periodical literature began early and has flourished, if not continuously at least richly. In the first half of the 19th century all archival periodicals were given over to publication of research; by the mid-20th century, in spite of the demises and suspensions resultant from two world wars and a cold war, more than 75% of the archival periodical literature was devoted to technical matters. Especially significant titles among the older periodicals are the *Bibliothèque de l'école des Chartes,* the *Archivalische Zeitschrift, Archivi, Nederlandsch Archievenblad* all of which survived World War II. Postwar developments of outstanding importance were *Indian Archives* (India), *Archives* (England), *ABCD—Archives, Bibliothèques, Collections, Documentation* (France), *Der Archivar* (Germany), *Mitteilungen des österreichischen Staatsarchivs* (Austria) and *Archivum* (international). Almost all significant periodicals contain not only articles on national history, technical matters, development in theory, book reviews and news notes but also articles on archival matters in other countries. Some likewise report on professional literature over the world. Outstanding in this respect is the annotated and classified list which appeared annually in the *American Archivist* (established 1938) after 1943 and in *Archivum* after 1952. At mid-20th century, after 150 years of modern theory and practice, the universal and definitive bibliography of archival administration, records management and manuscript curatorship had yet to be compiled.

Organizations.—Professional associations have been formed in many but by no means all countries in which archival administration and the status of archivists has been fully developed. There is no handbook which lists these, and there are no criteria for divining their existence—wealth of archival resources, independent age of country, size of country and nature of administration all are invalid guides. The Vereniging van Archivarissen in the Netherlands, which was founded in 1891, drew its members only from professional archivists. The British Records association, on the other hand, numbered among its members after it was established in 1932 not only practising archivists but curators of manuscript collections, institutions, librarians and "friends of archives." In some countries, such as Spain, Belgium and Poland, for example, the archivists united with their neighbours, the librarians and museum curators, in a combined association. Whatever the precise nature of the organization, the trend in the middle and latter part of the 20th century clearly was toward association for mutual development. Mexican archivists held their first national congress in 1944. In the United States, though the first conference of archivists was held in Dec. 1909, the Society of American Archivists was not organized until 1936. The Associazione Nazionale Archivistica Italiana, founded in 1950, held its first national meeting that same year. The programs and the viewpoints vary considerably as evidenced by the published papers and minutes of meetings. The Society of American Archivists, which had a vigorous committee on international relations from its inception, was the primary sponsor of the movement to found the International Council on Archives. This was created under the auspices of UNESCO in June 1948 as a professional organization to strengthen relations among archivists of all lands and among all agencies concerned with the custody of archives; to promote the preservation and to facilitate the use of archives; and to promote and co-ordinate international activities in archival administration. The first International Congress on Archives was held in Paris in 1950 and was followed by others at three- or four-year intervals. Archivists participated also in the International Congress of Librarians and Archivists held in Brussels in 1910 and in the permanent International Commission of Historical Sciences (1923–) that created in 1929 a commission on archives which, understandably, dealt with the subject from the point of view of the research scholar. The first meeting of the committee on archives of the Commission on History of the Pan American Institute of Geography and History was held in 1950 in Havana, where it considered such fundamentals as an inter-American training school; the collection of information on archival laws, buildings and microfilm facilities; the development of a co-operative microfilming project for acquisition of correlative materials; and the establishment of an inter-American periodical for dissemination of professional information. The Ibero-American-Philippine Congress on Archives, Libraries and Copyright held in Madrid during the fall of 1952 had much in common with the regional meeting just mentioned and with the International Congress of Archivists, Librarians and Museum Curators of the Caribbean area which was held about a decade earlier.

ARCHON, "leader" or "ruler," a term used widely among the ancient Greek city-states for the chief magistrate or magistrates. It had its origin in the period (somewhere between *c.* 1000 B.C. and 682 B.C.) when the kings (basileis) were being superseded by aristocrats.

At Athens executive power was in the hands of nine archons by the middle of the 7th century B.C. They were not a college, but the religious, military and judicial functions once discharged by the kings were divided among them. Probably the first to be instituted was the archon (later known as eponymous archon since he gave his name to his year of office; the list of annual archons began in 682/681 B.C.). He was the principal civil and judicial officer and may have presided over both council (boule) and assembly (ecclesia) (*see* BOULE; ECCLESIA). Next came the polemarch, commander in war and judge where foreigners were involved. Third, the kingship survived in the person of an annual basileus, who was the chief religious officer, and in that capacity presided over the Areopagus (*q.v.*) when it sat as a homicide court. Lastly there were six thesmothetae (determiners of customs), probably set up to relieve the other archons of certain not readily definable judicial functions. It is uncertain whether at this stage the archons were elected by the Areopagus or by the ecclesia. Only nobles by birth (eupatridae) were eligible. Probably no one was allowed to hold any of the various archonships twice. Archons became life members of the Areopagus, and this body exercised a general supervision over their administration, especially in the judicial sphere.

Solon (*q.v.*) in 594/593 B.C. removed the eupatrid monopoly of the archonships by making eligible members of the top or of the top two property classes. Rivalry for the office continued, and in 580/579 B.C., after a 14 months usurpation by Damasias, archon during 582/581, the contending parties reached a temporary compromise, under which the powers either of the eponymous or of all nine archons were exercised by a board of ten archons whose membership was shared between the factions. The Pisistratid tyrants (561–510 B.C.) managed to fill the archonships with their own adherents, their one violation of constitutional forms.

Under the Cleisthenic constitution (508–487/486) archons were elected directly by the ecclesia and leading politicans held the office. But from 500 B.C. the election of ten tribal commanders (strategoi), free from the ban on iteration, began to sap the authority of the polemarch, and at the battle of Marathon in 490 B.C. he was overshadowed by the prestige of the strategos, Miltiades.

In 487/486 mixed sortition was introduced (or restored) for elections. The archons were chosen by lot from 500 previously elected candidates. Since eligibility was still restricted to the two top classes, the change was not prima facie democratic. At about the same time the archons lost their more important functions; from this time onward no archon made any mark in politics and the polemarch played no part in army command. In the administrative sphere the archons were replaced by the strategoi, who could be re-elected. The archons were now primarily judicial officers, the eponymous archon dealing with family and property matters, the polemarch with litigation involving foreigners, the basileus with homicide and certain religious cases and the thesmothetae with a miscellany, particularly constitutional trials. Here too, however, their powers were lessened by the gradual conversion of the popular courts (*dikasteria*) from courts of appeal to courts of first instance. By the middle of the 5th century the magistrate no longer gave his own judgment. He merely conducted a preliminary inquiry (*anakrisis*) into such matters as the status of the litigants, the nature of the plea and of the defense and then brought the case before a jury, presiding over the hearing, but with none of the modern judge's responsibility for directing the jury on matters of law.

In 458/457 B.C. eligibility was extended to the third property class. Between that date and the time of Aristotle (384–322 B.C.) two further changes were made: (1) members of the fourth property class were admitted in fact, though they remained theoretically ineligible; (2) selection by lot was substituted for the preliminary selection of candidates, so that election was by double sortition. Before entering office archons had to undergo an examination (*dokimasia*) by boule and law courts into birth qualifications, physical fitness, etc., and on laying down office another examination (*euthuna*) into their conduct, especially financial, while in office. Misconduct might involve penalties inflicted by a court.

The importance of the archons in the fully developed democracy at Athens has perhaps been unduly depreciated. Their judicial function was never pure routine, and the Areopagus, composed entirely of former archons, retained a certain esteem, especially in times of political trouble.

At Delphi eponymous archons can be traced back to the beginning of the 6th century B.C., and archons are found elsewhere in Greece, in Phocis and in eastern and western Locris at an early date; for example, there were three at Halae (on the Euboean channel) in the early 5th century. At Plataea there was probably already an archon with religious functions at about this time. During the 5th century the institution spread widely in the Aegean islands, no doubt mainly because of the influence of Athens, and thence in the Hellenistic period to the cities of Asia Minor. A parallel to the Athenian ban on iteration is found in Drerus and Gortyna, in Crete, where the chief magistracy could not be held a second time within ten and three years respectively. From the 4th century B.C. archons functioned as the highest titular magistrates in the Boeotian and Thessalian confederacies side by side with archons of their constituent cities, and communities of the Aetolian confederacy had boards of three archons. An archon was head of the Roman emperor Hadrian's organization for furthering Panhellenic unity, the Panhellenium, which had its headquarters at Athens.

ARCHPRIEST, a title, known since the 4th century, of a Christian priest holding office over other priests. At first his duty was to assist the bishop of a city, but as Christianity ceased to be confined to the towns the priest who, like a rural dean, presided over a group of parishes in the countryside was also called archpriest (6th century). Later the title became an honorary one, as it still is, being the highest rank a married priest can reach in the Orthodox Eastern Churches. The head clerics of the three chief Roman basilicas became cardinal archpriests, but since the 18th century only the cardinal archpriest of St. Peter's has retained any special powers.

See A. Armanien in R. Naz (ed.), *Dictionnaire de droit canonique*, vol. i, col. 1004–26 (1935). (H. M. W.)

ARCHYTAS (fl. 400–350 B.C.), of Tarentum in southern Italy, Greek scientist and philosopher, was a close friend of Plato. An influential figure in the public affairs of Magna Graecia, he was several times commander in chief of his city.

Archytas was a Pythagorean and among the first and the most gifted leaders of that school (*see* PYTHAGORAS AND PYTHAGOREANISM). He solved the geometrical problem of doubling a cube, the so-called Delian problem, by an essentially kinematic construction in three dimensions.

In acoustic theory, whereas the notes emitted by a stringed instrument had been correlated with the length or tension of the strings, Archytas maintained that they were due to a movement or perhaps displacement of air and correlated with the speed of impact on the strings and on the ear. For such reasons he has been called the originator of mathematical mechanics. It is quite possible that we owe to him the main contents of Book viii of Euclid's *Elements*. For he advanced the study of continued proportion ($a:b = b:c = c:d \ldots$), providing definitions of arithmetical, of geometric and of harmonic means and a proof that there is no geometric mean between n and $n + 1$. These were contribu-

tions to musical theory, since they enabled him to obtain enharmonic intervals in addition to those of the chromatic and diatonic scales (*see* GREEK MUSIC [ANCIENT]).

Of the nonmathematical fragments handed down under his name few are likely to be genuine. But in some the philosophical anachronisms may be due only to rewriting in later times (*e.g.*, the fragment of *On Law and Justice* from Stobaeus, *Florilegium*, iv, 1, 135–138; 5, 61). Although Plato made use of his mathematical work, we should neither expect nor infer from the evidence that Archytas was influenced by Plato's philosophy.

BIBLIOGRAPHY.—Fragments and references to Archytas are collected in H. Diels and W. Kranz, *Fragmente der Vorsokratiker*, vol. i, 7th ed. (1954). Fragments usually thought spurious can be found, with Latin translation, in F. G. A. Mullach, *Fragmenta philosophorum Graecorum*, vol. i and ii (1865–67). *See* further A. Delatte, *Essai sur la politique pythagoricienne* (1922); E. Frank, *Plato und die sogenannten Pythagoräer* (1923); T. L. Heath, *History of Greek Mathematics*, vol. i (1921); and B. L. Van der Waerden, *Science Awakening*, Eng. trans. by A. Dresden (1954), and "Die Harmonienlehre der Pythagoreer," *Hermes*, vol. lxxviii (1943). (A. C. LD.)

ARCOT, a town in Madras state, India, is on the Palar river 70 mi. W.S.W. of Madras city and 4 mi. S. of the nearest station, Walajah Road, on the Madras-Bangalore line of the Southern railway. Pop. (1961) 25,029. Arcot was the capital of the Muslim nawabs of the Carnatic (*q.v.*). In the 18th century it changed hands between Delhi, Maratha, Mysore, French and British regimes. It was the scene of the 50-day defense by Robert Clive (*q.v.*) in 1751. It was finally annexed in 1801 by the British, who in 1867 imposed the title "prince of Arcot" on the head of the nawab family, who by then had no jurisdiction. Arcot gives its name to two districts, North Arcot and South Arcot, and is in the former.

NORTH ARCOT DISTRICT is mountainous in the north and in the west, where the Javadi hills rise to 3,800 ft. The population, which includes many Christians, was 2,859,157 in 1951 and 3,146,326 in 1961. Area 4,942 sq.mi. It is drained by the nonperennial Palar (which rises in the Javadis and flows eastward to the Bay of Bengal) and its tributaries. The district headquarters are at Vellore (*q.v.*), 8 mi. W. of Arcot town. Essentially agricultural, with rice and millet crops, North Arcot also has several traditional and modern industrial centres. Vellore, Ranipet (22,974), 4 mi. E. of Arcot, and Ambur (39,455), 27 mi. S.W. of Vellore, have tanneries, and the name "Ranipet variety" is given on the London market to leather exported from the region. Arni (31,351), 21 mi. S.E. of Vellore, and Walajahpet (13,179), 9 mi. E. of Arcot, are ancient silk-weaving centres. Ranipet also manufactures ceramic ware, sulfuric acid and superphosphates; and metal poles, guttering and shafting are produced at Arkonam (30,658), 37 mi. E.N.E. of Vellore.

The most notable monument is the Hindu "Holy Beacon" temple at Tiruvannamalai, 48 mi. S. of Vellore, so-called from the large lamp lit there during one of the festivals. It is an ancient foundation, extended *c.* 1300 A.D. and greatly enlarged under the 17th-century Naik dynasty. The shrine is approached through three concentric walled enclosures, pierced by massive sculptured *gopuras* or gate towers, and a thousand-pillared *mandapam* or hall. At Mahedravadi, 30 mi. E.N.E. of Vellore, are the ruined town and rock-cut temples built in the early 7th century A.D. by Mahendra-varman I of the Pallava dynasty.

SOUTH ARCOT DISTRICT is mainly a low lying sandy tract, with loamy areas on the coast and in the south. Pop. (1961) 3,047,973. Area 4,204 sq.mi. It is irrigated extensively by wells, both artesian and ordinary, and drained by the Ponnaiyar and Vellar rivers and in the south by the Coleroon, the main deltaic distributary of the Cauvery (*q.v.*). Rice and millets are grown but the district's specialized crop is peanuts. The district headquarters are at Cuddalore (*q.v.*). Cotton and silk weaving, especially of coloured cloths for export to Malaya, is carried on in many places, and at Nellikuppam (22,168), 6 mi. N.W. of Cuddalore, are a large distillery and a sugar refinery.

Neyveli, on the Southern railway 20 mi. W.S.W. of Cuddalore, is the centre of a lignite field with estimated reserves of 2,000,000,000 tons. The more easily workable deposits, about 200,000,000 tons, with an average seam thickness of 55 ft. at a mean depth of 180 ft. are, however, confined to an area of 5½ sq.mi. An integrated mining and power project was begun in 1961, involving the mining of 3,500,000 tons of lignite and its utilization to generate 200,000 kw. of electricity.

Chidambaram (*q.v.*) is the seat of Annamalai university. At Gingee (Jinji), 45 mi. N.W. of Cuddalore, is the great rock fortress which, captured by Sivaji in 1676, was the centre of Maratha revival against the Moguls in the late 17th and early 18th centuries. Built by the Hindu dynasty of Vijayanagar (*q.v.*) in the 15th century, it was improved by the British in the early 19th. (G. KN.)

ARCTIC, THE, the area of the far north characterized by distinctively polar conditions of climate, plant life, etc. The term is derived from the Greek *arktos*, "bear," referring to the northern constellation of the Bear. It has sometimes been used to designate the area within the Arctic circle—a mathematical line, drawn at 66° 30′ N., marking the southern limit of the zone in which there is at least one annual period of 24 hours during which the sun does not set and one during which it does not rise. However, this line is without value as a geographical boundary, since it is not keyed to the nature of the terrain.

While no dividing line is completely definitive, a generally useful guide is the irregular line marking the northernmost limit of the stands of trees. The regions north of the tree line include Greenland, Spitsbergen and other polar islands; the northern parts of the mainlands of Siberia, Alaska and Canada; the coasts of Labrador; the north of Iceland; also, a strip of the arctic coast of Europe. However, the last-named area is classified as subarctic because of other factors. The criterion of temperature range for designating regions as arctic is discussed below in *Climate,* and methods used for classifying oceanic areas in the *Arctic Ocean* section.

Conditions typical of arctic lands are extreme fluctuations between summer and winter temperatures; permanent snow and ice in the high country, and grasses, sedges and low shrubs in the lowlands; and permanently frozen ground (permafrost, *q.v.*), the surface layer of which is subject to summer thawing. Three-fifths of the arctic terrain is outside the zones of permanent ice. The brevity of the arctic summer is partly compensated by the long daily duration of summer sunshine.

International interest in the arctic and subarctic regions has steadily increased during the 20th century, and particularly since World War II. Three major factors are involved: the advantages of the north pole route as a short cut between important centres of population; the growing realization of economic potentialities such as mineral and forest resources and grazing areas; and the importance of the regions in the study of global meteorology.

Arctic research was one of the major activities of the International Geophysical year (IGY) (*q.v.*) of 1957–58, when data were gathered and exchanged by more than 300 experimental stations. In the Aug. 1958 transpolar voyage of the U.S. submarine "Nautilus," over 1,800 mi. of the journey were made under the ice pack. In the same month the U.S. submarine "Skate" crossed the north pole and surfaced at an IGY drifting station. Many of the polar research projects were continued, with exchange of information through International Geophysical Co-operation—1959, after the close of the IGY. The most intensive program of arctic research and development, before and after IGY, was that of Soviet Russia.

The article below is divided into the following sections:

I. EXPLORATION

1. The Beginnings.—The earliest references to arctic exploration are shrouded in superstitious beliefs concerning the uninhabitable "frigid zone," and also in an obscurity resulting from inaccurate ideas of the shape of the earth and from primitive navigation techniques, which make it very difficult to interpret early maps and accounts of voyages. Probably the first to approach the arctic regions was a Greek, Pytheas, who in the 4th century B.C. made an astonishing voyage from the Mediterranean around Britain, and reached a place he called Thule, variously identified as the Shetlands, Iceland and Norway. The accounts of this remarkable explorer were for centuries discredited but the idea of his Thule, shrouded in fog and believed to be the end of the earth, caught the imagination of many.

Iceland is known to have been visited by Irish monks in the 8th and 9th centuries, but it was the Vikings from Norway who settled the island, late in the 9th century. In the course of the next four centuries these hardy seamen established trade routes to the White sea; discovered Greenland (*c.* 982) and founded two settlements on the southwest coast (which disappeared, for unknown reasons, before the 16th century); reached the coast of North America; and probably also reached Spitsbergen and Novaya Zemlya. Unfortunately, however, they left scant records of their voyages, and many of the places they visited had later to be rediscovered by others.

2. The Northeast Passage.—After a long period of inactivity following the decline of the Norsemen, leadership in arctic exploration was assumed in the early 16th century by the Dutch and the English. The motive was trade with the far east. The known sea routes around the southern tips of Africa and South America were claimed as a monopoly by Portugal and Spain respectively, and besides were long and arduous; the overland routes were even worse. There remained, however, the northern latitudes, and the attempts of English and Dutch merchants to find a northeast and northwest passage gave a strong stimulus to exploration of the arctic.

In 1553 the English sent three ships to the northeast under the command of Sir Hugh Willoughby, with Richard Chancellor as chief pilot. Willoughby, with two ships, wintered in a harbour on the Kola peninsula, where he and his men all perished. Chancellor, who in the "Edward Bonaventure" had become separated from the others in a gale, reached what is now Archangel, and made an overland journey to Moscow (1,500 mi. in all) before returning home. It is interesting to note that these waters were already well known to Russian seamen, who used the route around North cape to western Europe as early as 1496, but this was not generally known at the time.

After Chancellor's voyage the Muscovy company was formed and there grew up a very lucrative trade with Russia, the success of which rather distracted the minds of the English from the northeast passage. Nevertheless, in 1556 Stephen Borough sailed in the "Searchthrift" to try to find the Ob river. He was stopped by ice and fog at the entrance to the Kara sea, which he described in such discouraging terms that it was not until 1580 that another English expedition, under Arthur Pet and Charles Jackman, attempted its passage. They, too, failed to penetrate it and England lost interest in the northeast passage.

In the meantime, however, the Dutch had taken up the search, largely because of the efforts of Olivier Brunel, who in 1565 established a trading post at Archangel, to the consternation of the English traders. In the course of an eventful career Brunel made an overland journey to the Ob, and in 1584 tried to reach it by sea, but like Pet and Jackman he got no farther than Yugorski strait. He was followed by Willem Barents, an outstanding seaman and navigator, who in 1594 discovered Novaya Zemlya and sailed to its northern tip; his two companions, Cornelis Nai and Brant Tetgales, penetrated a little way through Yugorski strait into the Kara sea. In 1596, with Jan Cornelisz Rijp and Jacob van Heemskerck, he was more successful. Heading due north from Norway instead of following the coast around, Barents discovered Bear Island (Bjørnøya) and Spitsbergen, which, however, he mistook for Greenland. Rijp then went home with one ship, but Barents and Heemskerck in the other headed east and rounded the north of Novaya Zemlya. They were forced to winter in Ice Haven on the northeast coast and thus became the first Europeans to winter successfully in the arctic. They built a house of driftwood and passed the season with remarkable fortitude and success, although they were in almost every way unprepared for it. In the spring, the ship being hopelessly damaged, they escaped across the open Barents sea in two small boats. Barents died on the journey. In 1609 Henry Hudson, the Englishman, sailed in the "Half Moon" to the Barents sea in the service of the Dutch East India company, but his crew, afraid of having to winter like Barents, mutinied and forced him to sail west, where he explored the coast of North America north of Virginia and discovered the Hudson river.

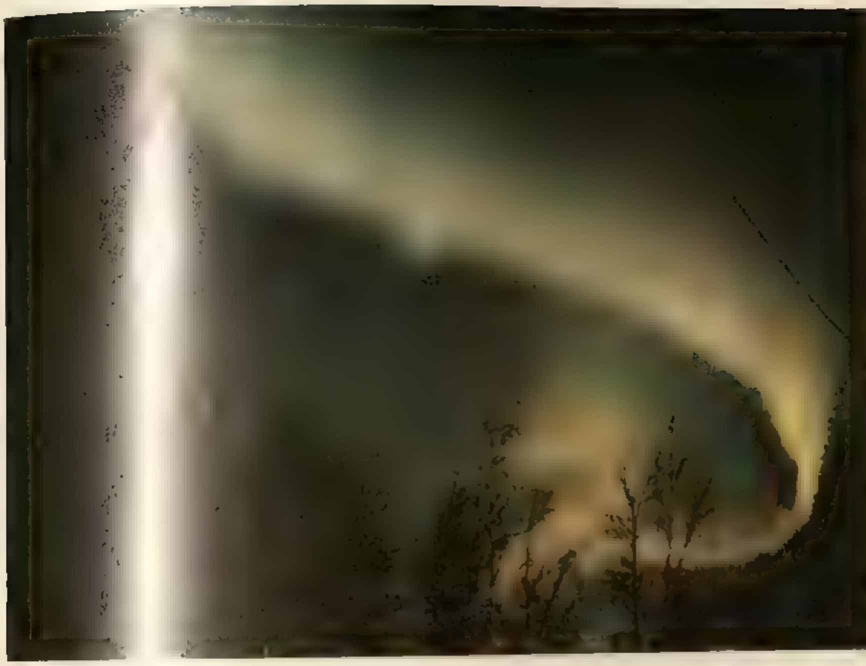
While the English and the Dutch were thus engaged, Siberia was gradually being annexed to Russia by bands of Cossacks spreading slowly eastward from the Urals. Conquering and trading, they reached the Pacific by the middle of the 17th century and traversed the northern coast line in small, flat-bottomed boats. One of these hardy wanderers, Semen Dezhnev, is believed to have sailed through Bering strait in 1648. Like the Norsemen, however the Cossack settlers made few records, and only rumours of the existence of a strait separating Asia from America reached the ears of Peter the Great. In order to find and above all to map the sea route to the east, this remarkable ruler conceived a series of expeditions which culminated in the Great Northern expedition (1725–42), and which under Peter's successors mapped the arctic coast line of Siberia as far east as the Kolyma river. The work of the expeditions was planned by Vitus Bering, a Dane with long service in the Russian navy, and directed by the admiralty college. In 1728 Bering, who himself took charge of activities in the Pacific sailed through Bering strait from the south, but because of bad weather failed to recognize its significance. In 1741 he crossed the North Pacific and landed on the coast of Alaska. Other important figures among the many who made up the Great Northern expedition are Lieut. S. Chelyuskin, who in 1741 reached the cape named after him, the most northern point of the Siberian mainland; and the brothers Laptev, who charted the coast from the Taimyr peninsula to the Kolyma river.

The question of the existence of a strait separating the continents remained uncertain until 1778 when Capt. James Cook, the great British explorer, sailed through Bering strait and reached North cape (now Cape Schmidt) on the Siberian coast. Unlike Bering, he was able to see both sides of the strait and so establish fairly conclusively that the continents were separate.

Attempts to complete the mapping of the north coast were made by a Russian merchant named Shalaurov in 1760–62 and by Joseph Billings, an Englishman in the Russian service, in 1787; it was eventually done by Baron Ferdinand von Wrangel, a Russian of Swedish parentage, in a series of sledge journeys (1820–24).

Wrangel's companion, P. F. Anjou, worked in the New Siberian Islands. These strange islands of silt and ice were discovered in 1770 by a merchant named Lyakhov, who saw caribou coming south to the mainland and followed their tracks north. The islands produced a fortune in mammoth ivory and were further explored and mapped in the years that followed, notably by an official survey party under an exile called Hedenström.

The main features of the northeast passage were now discovered and mapped; it remained to navigate it successfully. One attempt to do so, by an Austrian expedition under Julius Payer and Karl Weyprecht in 1872–74, led to the accidental discovery of



The aurora borealis over Fairbanks, Alaska, in April 1960

Franz Josef Land. While trying to sail around the north end of Novaya Zemlya their ship, the "Tegetthoff," became caught in the ice and drifted helplessly north and west for over a year, to be deposited by the ice on the shore of a new land. In the spring of 1874 Payer made a long sledge journey, reaching the northernmost point of the archipelago. The ship had to be abandoned, and the party sailed in small boats to Novaya Zemlya, where they were picked up by a Russian fishing vessel.

The first successful navigation of the passage was accomplished in 1878–79 by one of the greatest of arctic explorers, the Swedish Baron A. E. Nordenskiöld, who saw in it not so much a route to the far east as an avenue of trade between Siberia and the rest of the world. After two reconnaissance trips to the Yenisei in 1875 and 1876, Nordenskiöld set out in 1878 in the "Vega" accompanied by three cargo ships, two bound for the Yenisei and one for the Lena. Aided by a good ship and a year of rather light ice conditions, he managed to reach the Chukchi peninsula before being forced to winter only 120 mi. from the Bering sea. The passage was next navigated from east to west by Comdr. B. A. Vilkitski of the Russian navy, who was engaged in hydrographic work. In 1913, while trying to pass Cape Chelyuskin, he was forced north and discovered Severnaya Zemlya, first called Nicholas II Land. He had to turn back and winter on the Pacific coast but succeeded in completing the passage in 1914–15. Two west-east attempts in 1912 by G. L. Brusilov and V. A. Rusanov ended disastrously with the almost complete loss of both expeditions. In 1932 the icebreaker "Sibiryakov" was the first to make the passage in one season, sailing from west to east.

3. The Northwest Passage.—The search for the northwest passage may be said to have begun with the discovery of America, for the voyages of Cartier and his successors to the St. Lawrence, and the Cabots and Corte Reals to Newfoundland and Labrador, were all undertaken with the aim of finding the passage. The first such voyage to enter the arctic, however, was that of Sir Martin Frobisher in 1576. At this time the map was a blank between southern Labrador and Greenland. To complicate matters further, there existed a spurious map published in 1558 of the voyage of Niccolò Zeno in 1380, which showed an entirely imaginary country called Friesland lying between Iceland and Greenland. Because of the supposed existence of this land confusion in mapping and identifying newly discovered lands persisted for 200 years.

Frobisher set out with the "Gabriel" and "Michael" and a tiny pinnace of ten tons. He made his North American landfall on the southeast coast of Baffin Island, after weathering terrible storms in which the pinnace was lost with all four of its crew and the "Michael" deserted and went home. In the "Gabriel" Frobisher sailed about 60 mi. up the long inlet named after him, which he took to be a strait, and brought home among his trophies a rock sample which was identified wrongly as containing gold. The northwest passage was forgotten, and in the next two years Frobisher made two further voyages for the sole purpose of establishing a gold mine. The last voyage was an astonishing enterprise

FIG. 1.—SIGNIFICANT GEOGRAPHICAL LOCATIONS OF THE ARCTIC

involving 15 ships, and had the aim of founding a settlement of 100 men. Included in the cargo was a prefabricated house. The ships, however, were scattered by storms, at least one was sunk, and Frobisher, unable to set up his colony, loaded the remaining ships with ore and returned home, only to find that his cargo was worthless.

Next to seek the passage was John Davis, one of the finest of the early seamen and something of a scientist as well. In three voyages, 1585–87, Davis rediscovered Greenland (lost since the decline of the Norse settlements); he visited the southeast coast and sailed up the west coast to beyond Disko Island (72° N.). He also traced the coasts of Baffin Island and Labrador from Cape Dyer south. Davis showed great imagination in his dealing with the Greenland Eskimos. He took musicians with him and had his sailors dance to the music, thus immediately establishing cordial relations with these sociable people.

In 1602 George Weymouth sailed a short way into Hudson strait, and in 1610 Henry Hudson made his last voyage, sailing the "Discovery" into Hudson bay and down to James bay, where he was forced to winter. In the spring there was a mutiny aboard; Hudson and about eight of his crew, including his young son, were set adrift in a small boat to die, while the mutineers sailed the ship home. Retribution, however, overtook the ringleaders in Hudson strait, where they were killed by Eskimos in one of the rather rare instances when these peaceful and good-natured people have attacked explorers. The remnant that reached England in September was imprisoned; nothing was ever heard from the deserted men.

The discovery of Hudson bay led to a long series of voyages seeking a western outlet to this large inland sea, and at the end of 20 years its shores were fairly well known. Sir Thomas Button in 1612–13 (with Robert Bylot, a Hudson survivor, as pilot) was the first to reach the west coast of the bay, wintering near the site of York Factory and discovering Roes Welcome sound; William Baffin, again with Bylot, sailed halfway up the northeast coast of Southampton Island in 1615; Jens Munk, a Dane, wintered at the mouth of the Churchill river in 1619–20, where nearly all his men died of scurvy, only Munk and two others surviving to sail one of the two ships home; and in 1631 Luke Foxe sailed into Foxe channel.

In the meantime Baffin, the outstanding navigator of his day, had explored Baffin bay (1616), but the significance of this exploration was not recognized for 200 years. With Bylot as master of his ship (Hudson's old "Discovery") Baffin sailed up the west coast of Greenland to the head of Baffin bay (78° N.) and down the west side of the bay, discovering the three sounds that lead out of it, Smith, Jones, and Lancaster. Unfortunately, he reported that all three were merely bays and that there was no passage out of Baffin bay. Even more unfortunately, his map was never published, and in time the very existence of "Baffin's bay" came to be doubted. Search was continued in the Hudson bay area up to the end of the 18th century, but at a greatly reduced pace. By that time traders were opening up the interior and hope of a passage by this route was fading.

The 19th century brought an entirely new era. Up till that time the search had been undertaken mainly by merchants; now it was the turn of governments. The end of the Napoleonic Wars had left the British navy relatively unemployed and the British government, spurred by the enthusiasm of Sir John Barrow, secretary to the admiralty, was persuaded to equip a whole series of large naval expeditions for the discovery of the northwest passage. The first of them, under Capt. John Ross in 1818, retraced almost exactly Baffin's journey of two centuries earlier, and repeated his error of mistaking the sounds for bays. Second in command to Ross was Lieut. W. E. (later Sir William Edward) Parry. He was not convinced that no sound existed, and in 1819–20, in H.M.S. "Hecla" and "Griper," he made a voyage through Lancaster sound to Melville Island in the western part of the archipelago, where he wintered. Blocked by ice in McClure strait, which he could not penetrate, he next (1821–23) tried the route through Foxe channel, spending two winters in Foxe basin. Again he was stopped by ice in the narrow Fury and Hecla strait (named after the two ships he used on this expedition). A number of rather unsuccessful ventures followed. Parry on a third voyage (1824–25) explored Prince Regent inlet; Capt. G. F. Lyon and Capt. George Back made unsuccessful attempts to reach Repulse bay; and Capt. John Ross, on a privately financed venture in 1829–33, sailed down Prince Regent inlet into the Gulf of Boothia, passing by one of the keys to the northwest passage, the narrow Bellot strait, which washes the northernmost tip of the North American continent. The latter expedition added greatly to the extent of mapped territory, mostly through the work of Ross's nephew, J. C. Ross, who established the position of the north magnetic pole in southwest Boothia peninsula. After three winters trapped in the ice, Ross had to abandon his ship, the "Victory," and retreat by sledge and boat, spending a fourth winter on the way before being picked up by a whaler in Lancaster sound.

In the meantime the British were also attacking the problem from the west by both sea and land. In 1819–22 and 1825–27 two expeditions under Capt. John Franklin, working over land and by boat from wintering bases in the Mackenzie basin, surveyed the coast line from Turnagain point, about 200 mi. E. of the Coppermine river, to Cape Beechey, Alaska. There Franklin almost made contact with the survey of Lieut. F. W. Beechey, who in 1825–26 reached Point Barrow from the west. In 1833–35 Capt. George Back discovered the Back river and mapped it to its mouth in Chantrey inlet, and in 1837–39 P. W. Dease and Thomas Simpson, Hudson's Bay company employees, made three coastal journeys by boat, filling in the gap in the Alaska coast line left by Franklin and joining Franklin's survey to Back's at Chantrey inlet. In 1847 another Hudson's Bay company employee, John Rae, joined Parry's Fury and Hecla strait to Ross's survey in the Gulf of Boothia. Rae was a most remarkable traveler, far ahead of his time in adopting Eskimo methods and living off the land.

Most of the continental coast line and a considerable amount of the Canadian arctic archipelago had now been charted, and still the northwest passage remained elusive. The British government was getting tired of the project but prepared to send out one last expedition. This was the famous and tragic last voyage of Sir John Franklin, who sailed into Lancaster sound in 1845 in H.M.S. "Erebus" and "Terror" and was never seen again. The loss of this expedition produced a reaction of profound shock and resulted in a 12-year search which contributed tremendously to geographical knowledge. At its peak in 1850 as many as 14 ships were in the area at the same time and a further expedition was at work from the mainland. The story eventually pieced together was that Franklin had wintered at Beechey Island at the west end of Lancaster sound, after sailing up Wellington channel to 77° N and in the spring of 1846 turned south down Peel sound, hitherto unnavigated, to Victoria strait, off the north tip of King William Island, where his ships eventually had to be abandoned. There were no survivors.

The first to become anxious was Sir John Richardson, a veteran of Franklin's earlier expeditions, who in 1847–49 conducted a search along the northwest mainland coast, accompanied by Rae. The first official search parties were sent out in 1848; Sir James C. Ross, with "Enterprise" and "Investigator," was to enter from the east, and Capt. Henry Kellett, with the "Herald" and "Plover" had orders to stand by in Bering strait to meet Franklin on his way out. Ross wintered in Somerset Island and traced most of its coast line before returning in 1849 without news. In an atmosphere of mounting alarm a more thorough search was made in 1850. Capt. Horatio Austin wintered with four ships, the "Resolute," "Assistance," "Intrepid," and "Pioneer," off the south coast of Cornwallis Island, from which base extensive sledge trips traced many miles of coast line. Two more ships, under Capt. William Penny, a whaler, were in the same area, as was also Sir John Ross, now 73 but still active. The first U.S. expedition to the arctic, financed by Henry Grinnell and led by Lieut. E. J. de Haven, sailed in the "Advance" and "Rescue" to Wellington channel. Franklin's winter quarters at Beechey Island were found by Austin's and Penny's expeditions, but no record had been left to point the way from there.

At the same time, in 1850, Capt. Richard Collinson was to enter from the west and meet Austin in a pincer movement. His two

ships became separated in the Pacific, however, and operated independently. Comdr. Robert McClure in the "Investigator" discovered Prince of Wales strait, rounded Banks Island by the west and entered Mercy bay on the north coast, where the ship remained frozen in for two years and was finally abandoned. McClure and his men were rescued by another expedition and returned home in 1854 by the eastern route. He was thus the first to make the northwest passage, though in more than one ship and partly on foot. Collinson in the "Enterprise" spent three years in Victoria Island, reaching Victoria strait. There he was within a short distance of the place where Franklin's ships had been abandoned, as was also Rae, traveling by boat two years earlier. Neither found any clues. In 1852 a private expedition financed by Lady Franklin and led by a whaling captain, William Kennedy, discovered Bellot strait, named after a French volunteer in the search.

After this the search moved north, which was generally thought to be the most likely direction; only Lady Franklin held firmly, and correctly, to the view that her husband had gone south as directed by his orders. In 1852 Capt. E. Inglefield in the "Isabel" sailed north up Smith sound to 78° 35′ N., and another large expedition, under Sir Edward Belcher and Henry Kellett, sailed into Lancaster sound with Austin's four ships, plus a supply vessel, the "North Star." Splitting into an eastern and a western party and spending two winters in the arctic, this expedition mapped many miles of new coast line north of Lancaster sound, rescued the survivors of McClure's expedition, and then without apparent justification abandoned all four ships in the ice and sailed home in the "North Star." One ship, the "Resolute," was later found drifting in good condition in Davis strait by a whaler, sailed to New England, refitted and returned to the British government by the United States.

In 1853 an American, E. K. Kane, sailed in the "Advance" to Kane basin, wintering twice and searching northward to Kennedy channel. In the same year Rae was sent by the Hudson's Bay company to complete the charting of the mainland coast between Chantrey inlet and Boothia. The company had given up the search as hopeless, but ironically it was this expedition that brought back the first real news, obtained by Rae from Eskimos in Pelly bay and backed by identifiable relics. The British government considered the search closed, but Lady Franklin was not satisfied; she financed a final expedition in the "Fox" under Capt. F. L. McClintock, who had been on three previous expeditions and was largely responsible for developing the sledging techniques used during the search. He traveled around the coasts of King William Island, finding many bodies and relics of the expedition, and also the only record left by it, at Victory point.

So the northwest passage was at last found to be a reality, and official recognition went to McClure as its discoverer, though Franklin too had proved its existence and should share the honour. An unsuccessful attempt to navigate it was made by Allen Young in the "Pandora" in 1875. In 1903 Roald Amundsen, the great Norwegian explorer, sailed down Peel sound in his tiny yacht "Gjöa" and passed around the east side of King William Island, where he spent two winters taking magnetic and other scientific observations. After a third winter spent west of the Mackenzie he passed through Bering strait in 1906, the first to navigate the northwest passage. It was navigated again in 1940–42 and in 1944 by Henry A. Larsen of the Royal Canadian Mounted Police in the "St. Roch," west-east by way of Bellot strait and east-west in one season by Prince of Wales strait. In 1954 the first passage by a deep-draught vessel was made by H.M.C.S. "Labrador," a Canadian naval icebreaker.

4. Whale Fisheries and the Fur Trade.—Many advances in geographical knowledge were due, directly or indirectly, to the whale fisheries that flourished in the arctic for three centuries. On his first voyage in 1607, in the service of the Muscovy company, Henry Hudson sailed up the east coast of Greenland in search of a direct polar route to Cathay. Reaching 73° 30′ N., he turned east along the edge of the pack ice to Spitsbergen, and on his way home discovered Jan Mayen Island. He was impressed by the number of whales he saw and as a result of his recommendation a thriving whaling industry grew up, being carried on by English, Dutch, Danish, French and other companies, and continuing until the whales were gone. In the 18th century the whaling spread to East Greenland waters and in the 19th to Baffin bay, Hudson bay, and, after 1850, the Beaufort sea, where U.S. whalers played a prominent part. By 1920 the industry was dead.

Much of the geographical knowledge accumulated by the whalers was never recorded and died with them; some, especially in the early days, was deliberately suppressed so as to keep it from competitors, but a great deal also found its way onto the maps. The coasts of Spitsbergen were first mapped by Dutch and English whalers, and the Dutchman Cornelis Giles discovered an island east of Spitsbergen which was long known as Giles (Gillis) Land, now White Island. Later details were added by Norwegian sealers. The considerable part played by whaling captains in the Franklin search has already been noted; in addition, the names of many whalers are perpetuated on the maps of Baffin Island and Hudson bay. A whaler, William Adams, established the insularity of Bylot Island, and another, George Comer, made the first complete map of Southampton Island. Going farther west, Wrangel Island was discovered by Thomas Long, a U.S. whaler.

By far the most famous of the whalers were the William Scoresbys, father and son. Scoresby Sr., a farmer's son, was a first-rate navigator, inventor of the crow's-nest and other aids to ice navigation, and the first to suggest the use of sledges to reach the pole. His son, who inherited his father's talents and added to them a scientific education, wrote two important books on the arctic. In 1806 the Scoresbys reached 81° 12′ N., north of Spitsbergen, a record northing at the time, and in 1822 made a detailed map of the east coast of Greenland from 75° to 69° N.

Just as whaling led to improved knowledge of the coast lines, the fur trade helped to open the interiors of arctic lands. The Cossacks who settled Siberia were mainly engaged in this profitable trade, and the interior of Spitsbergen was first frequented by Russian hunters, who in the 18th century hunted the fur bearers almost to extinction. But it was in North America that the influence of the fur traders was greatest.

The formation of the Hudson's Bay company (*q.v.*) was a direct result of the 17th century voyages into Hudson bay in search of the northwest passage. Following an exploratory voyage by Capt. Z. Gillam in 1668, the company was incorporated in 1670 and a trading post established at the foot of James bay. Soon posts were set up on the west side of the bay at York Factory and Churchill, and these served as bases for further exploration. It was a hundred years, however, before the Hudson's Bay company made any real attempt to explore the hinterland, when Samuel Hearne was sent to look for a source of copper reported by Indians who traded at the coast. Hearne set out from Churchill with a band of Indians in 1770–71, and with them made a remarkable journey to the mouth of the Coppermine river, returning by way of Great Slave lake. In 1789 Alexander Mackenzie of the rival North-West company of Montreal traveled by canoe from Lake Athabasca down the Mackenzie river to the sea, establishing a second known point on the arctic coast. By the time the two companies merged in 1821 there were trading posts on Great Slave lake and down the Mackenzie to Ft. Good Hope; it was the existence of these posts that made possible the overland expeditions of Franklin and his successors, among whom were many Hudson's Bay company men.

Pushing westward from the Mackenzie through the mountains and into Alaska, the Hudson's Bay company met Russian traders working from the west coast. The Russians had established a colony in Alaska toward the end of the 18th century and carried on a vigorous trade at Kodiak, Sitka and other settlements. In 1831 Baron von Wrangel, governor of the colony from 1829 to 1834, established a post on St. Michael's Island and had the lower Yukon explored. Competition and strife between the Russian and British traders was ended by the purchase of Alaska by the United States in 1867 and the joint survey of the Alaska-Yukon boundary.

5. The North Pole.—The north pole did not become in itself a goal of exploration until fairly late; the few early expeditions that tried to reach the pole were looking for a polar route to the east rather than for the pole itself. After Hudson's first attempt in 1607, nearly 200 years elapsed before the British government

sent another expedition, under Capt. C. J. Phipps in 1773, to try to sail across the north pole. He got only as far as the north of Spitsbergen, and Capt. David Buchan in 1818 did no better. In 1827 Parry was the first to try the sledging technique suggested by Scoresby, breaking the latter's record by reaching 82° 45′ N.

All these attempts had been in the area between Greenland and Spitsbergen, which actually is not the accessible route to the Arctic ocean that it appears to be, owing to the strong southerly drift of the ice. The Franklin search opened a new route, up the west coast of Greenland. In 1860 I. I. Hayes attempted to reach the pole by this route in the schooner "United States." Hayes was a firm believer in a theory, then prevalent, that the polar sea was ice-free and that it could be reached by breaking through the fringing belt of pack ice. Ironically, he met with unusually heavy ice conditions and got only as far as Etah on the coast of Smith sound. In 1871 Charles Francis Hall, another American, with more luck and a better ship, reached 82° 11′ N. and charted both sides of the channel to its northern end at the entrance to the Lincoln sea. Hall himself died during the winter and his ship, the "Polaris," was caught in the ice on the voyage south and drifted to Smith sound, where it was almost wrecked. A party of 19, including an Eskimo mother with a two-month-old baby, became separated from the ship and drifted all winter on an ice floe, being picked up by a whaler in April 1873 off the coast of Labrador. In 1875–76 a British expedition under Capt. G. S. Nares in the "Alert" and "Discovery" reached the Lincoln sea by ship, the "Alert" wintering near Cape Sheridan on the north coast of Ellesmere Island, the "Discovery" farther south at Lady Franklin bay. Sledge parties in the spring traced the coasts of Ellesmere Island and Greenland to Yelverton bay and Sherard Osborn fjord respectively, and one, under Comdr. A. H. Markham, reached 83° 20′ N. over the pack ice, a new record northing.

In the meantime the Spitsbergen route was not neglected. In 1869–70 a German expedition under Karl Koldewey in the "Germania" sailed up the east coast of Greenland to 72° 30′ N. and traced it by sledge to Cape Bismarck. A second ship, the "Hansa," became separated and was crushed in the ice, and the crew drifted south on a floe and around Cape Farewell, reaching the settlement of Frederiksdal in safety. A. E. Nordenskiöld, the great Swedish explorer, made two journeys toward the pole from Spitsbergen, in 1868 by ship and in 1873 by reindeer sledge.

An entirely new approach was tried in 1879 by a U.S. expedition in the "Jeannette," led by Lieut. Comdr. G. W. de Long. At that time it was believed by many that Wrangel Island was a large land mass stretching far to the north, and de Long hoped to sail north as far as possible along its coast and then sledge to the pole. Accordingly, he sailed through Bering strait, but his ship was caught in the ice near Herald Island and drifted west for 22 months, passing north of Wrangel Island and revealing its limited extent. The "Jeannette" sank near the New Siberian Islands and the crew reached the Lena delta on foot, where many of them died, including De Long himself. A search expedition under Lieut. R. M. Berry surveyed Wrangel Island.

Wreckage from the "Jeannette" was found a year or two later on the southwest coast of Greenland, having apparently drifted right across the Arctic ocean, and Fridtjof Nansen, one of the greatest explorers of all time, conceived the daring idea that a ship might be made to do the same, thus providing a base for scientific investigation of the Arctic ocean and incidentally a means of reaching the pole. In a new vessel, the "Fram," specially designed to rise under lateral pressure and so avoid being crushed, Nansen left Norway in 1893 with Otto Sverdrup and sailed into the Kara sea. Near the place where the "Jeannette" sank they drove the "Fram" into the pack and began a drift that lasted almost three years and ended with the safe release of the vessel north of Spitsbergen in 1896; a formidable amount of scientific data was collected. Nansen himself left the "Fram" in 1895 with one companion, Hjalmar Johansen, in an attempt to reach the pole by sledge, starting from 84° N. in the longitude of Franz Josef Land and setting a new record of 86° 13′ N. before having to turn back and winter in Franz Josef Land. In the spring, by a strange and lucky coincidence, he met Frederick Jackson, a British explorer, and returned home in his ship. Jackson was investigating Franz Josef Land as a possible steppingstone to the pole, but on hearing Nansen's account gave up the polar attempt. In his three-year stay, however (1894–97), he revolutionized the map of this complicated collection of islands and did a great deal of valuable work.

Up to that time the desire to reach the pole had been coupled with that of mapping unexplored territory and collecting scientific data; after the "Fram" expedition there was no longer any doubt that the central part of the polar basin was an ice-covered sea, and that any land still to be discovered would be peripheral. The race for the pole then degenerated into an international sporting event. Several expeditions, following in Jackson's footsteps, tried to reach the pole from Franz Josef Land. Three were American: Walter Wellman in 1898–99, the Baldwin-Ziegler expedition in 1901–02, and the Fiala-Ziegler expedition in 1903–06. An Italian expedition led by the duke of the Abruzzi set a new record in 1900, when Capt. U. Cagni reached 86° 34′ N.

Robert E. Peary started working toward his polar journeys in 1891–92 and 1893–95 when he made two long journeys across northwest Greenland, discovering the largely ice-free Peary Land. He intended to use north Greenland as his jumping-off place, but later changed this to north Ellesmere Island, farther from the pole but more accessible. In 1898–1902 he laid a large supply cache in Lady Franklin bay from bases in Smith sound, sledged around the north coast of Greenland, and reached 84° 17′ N. from Cape Hecla, Ellesmere Island. In 1905, aided by the expert ice navigation of Capt. Bob Bartlett, he sailed in the "Roosevelt" to Cape Sheridan, near the "Alert's" old winter quarters, and from Cape Hecla set a new record of 87° 6′ N. He also sledged around the north coast of Ellesmere Island, mapping the coast from where Nares left off. In 1908–09 he returned and from Cape Columbia in 1909 made a sledge journey to the pole. His technique was to start with a large party and set up depots at regular intervals, the support sledges turning back one by one as the depots were laid. With Peary on the final dash were his Negro dog driver Matthew Henson and three Eskimos.

Just before Peary's return to the United States in Sept. 1909, Frederick A. Cook, an American who had been with Peary in Greenland in 1891–92 and who had spent 1907–09 in the arctic, announced that he had reached the pole the year before with two Eskimos, from the north point of Axel Heiberg Island. The matter aroused considerable controversy and to substantiate his claim Cook submitted his journal to the University of Copenhagen, which considered it inadequate proof; he did not appear to challenge the decision. The question of whether Peary or Cook, neither, or both, actually reached this theoretical point on the moving ice pack is hard to prove or disprove; but until there is fresh documentary evidence, or improved knowledge of the nature and movement of the ice in the Arctic ocean that supports a different interpretation of the existing documents, Peary's claim seems the more valid one. In any event, it was accepted by the U.S. congress and geographical institutions in many countries.

The first attempt to fly to the pole was made as early as 1897 when a Swedish scientist, S. A. Andrée, left Spitsbergen in a balloon. It was not until 1930 that the fate of Andrée and his two companions was known, when their bodies and diaries were found on White Island. In 1909 Walter Wellman made an unsuccessful attempt by dirigible, and in 1925 Amundsen, with two Dornier-Wal flying boats, reached 87° 44′ N. The first to reach the pole was Richard E. Byrd, who with Floyd Bennett as pilot flew from Spitsbergen to the pole and back on May 9, 1926. Two days later Amundsen and Umberto Nobile set off from the same base in a semirigid airship and flew across the pole to Alaska.

6. Scientific Exploration.—An important secondary motive in much of the exploration so far discussed was pure scientific curiosity, the desire to add to the general store of knowledge of the world. With the passage of time and the disappearance of the old dreams of gain and glory, this became more and more the primary motive of exploration, though it was sometimes combined with a hope of developing such mineral or other resources as may be found.

In 1875 an important proposal for international co-operation

in collecting scientific data was made by Karl Weyprecht, and the suggestion led to the setting up of the first International Polar year, 1882–83, during which stations throughout the arctic took observations and pooled the results. The countries participating were Norway, Sweden, Denmark, Finland, Russia, Holland, Germany, Austria, the United States and Great Britain. The 11 stations, reading eastward from Spitsbergen, were Ice fjord, Spitsbergen; Bossekop, north Norway; Sodankylä, Finland; west coast of Novaya Zemlya; Sagastyr Island, Lena delta; Point Barrow, Alaska; Great Slave lake; Lady Franklin bay, Ellesmere Island; Cumberland sound, Baffin Island; Godthaab, Greenland; and Jan Mayen Island. In 1932–33 a similar pattern was followed by the second International Polar year, but with more stations, and the technique was extended to cover the whole world in the International Geophysical year of 1957–58.

7. **Regional Exploration:** *Spitsbergen.*—Starting in 1827 a series of expeditions, most of them Swedish, surveyed Spitsbergen and studied its geology and natural history. Among those who carried out this work were B. M. Keilhau, Otto Torell and A. E. Nordenskiöld; the last-named made several visits between 1858 and 1873, when he sledged across North East Land. Sir Martin Conway crossed the interior of Vestspitsbergen in 1896–97, and in 1898 A. G. Nathorst explored the east coast and adjacent islands. Oceanographic and other work was done by the Dutch in the "Willem Barents" after 1878, by the prince of Monaco and W. S. Bruce (1898–1914), and by the Russian admiral S. O. Makarov in the icebreaker "Yermak" (1899). At the turn of the century coal mining was begun in Ice fjord and this led to further survey activity by Norwegian government expeditions and others. A British expedition from Oxford university under George Binney in 1924 was the first scientific expedition to make extensive use of an aircraft. (*See* also SVALBARD.)

The Russian Arctic.—Between 1821 and 1824 F. P. Litke of the Russian navy made four voyages to Novaya Zemlya, surveying the west coast and improving the mapping of Matochkin strait and the White sea coast, and in 1832–35 P. K. Pakhtusov surveyed much of the east coast of Novaya Zemlya. In 1880 Leigh Smith made the first of two voyages to Franz Josef Land, the first to sail a ship there under its own power. On his second voyage his ship, the "Eira," was nipped by ice and sank. Smith built a hut on the shore and wintered, surveying the south coast and collecting scientific data. In the spring the party sailed to Novaya Zemlya in small boats. In 1886 and again in 1893 and 1900–02 Baron E. von Toll, a Russian explorer, worked in the New Siberian Islands. He perished in an attempt to find Sannikov Land, an island reported north of the New Siberian Islands, which, like many similar "lands" in the arctic, probably does not exist. Some coordinated hydrographic work was done by the Russians in the Barents sea from 1898 to 1908, in the Kara sea from 1894 to 1904, and east of Cape Chelyuskin from 1910 to 1915.

In 1918 Amundsen set out in the "Maud" to emulate Nansen's drift in the "Fram" but with the hope of getting into a more northerly latitude by starting the drift nearer to Bering strait. He took three seasons to sail east through the northeast passage and it was not until 1922 that the "Maud" began its drift, under the scientific leadership of H. U. Sverdrup. In two years it was carried back to the New Siberian Islands, duplicating the path of the "Jeannette" rather than the "Fram," but useful scientific work was done throughout both phases of the expedition.

After the Russian Revolution in 1917 the scale and scope of exploration increased greatly, as part of the work of developing the northern sea route. Polar stations, of which five already existed in 1917, increased in number, providing meteorological, ice reconnaissance and radio facilities. By 1932 there were 24 stations, by 1948 about 80, and by the 1960s more than 100. The use of icebreakers, and, later, aircraft, as platforms for scientific work was developed. In 1929 and 1930 the icebreaker "Sedov" carried groups of scientists to Franz Josef Land and also to Severnaya Zemlya, the last major piece of unsurveyed territory in the Soviet arctic; it was completely mapped under G. A. Ushakov between 1930 and 1932.

The one-season voyage of the "Sibiryakov" through the passage in 1932 accomplished much scientific work and was the first to use the route north of Severnaya Zemlya. It gave a further stimulus to development of the sea route, and icebreaker operations to study sea and ice became annual. Particularly worth noting are three cruises of the "Sadko," which went farther north than most; in 1935 and 1936 the last unexplored areas in the northern Kara sea were examined and the little Ushakova Island discovered, and in 1937 the ship was caught in the ice with two others and forced to winter in the Laptev sea, adding valuable winter observations to the usual summer ones.

Greenland.—The history of modern Greenland may be said to begin with the voyage in 1721 of Hans Egede, a Danish-Norwegian missionary whose aim was to find and re-establish the Norse colonies. Traveling up and down the west coast, he found no survivors of the old colonists, but he stayed to found his own settlement at Godthaab and to begin the enlightened development of the country and its Eskimo people that has made Danish Greenland a model of colonial administration.

Greenland has received a great deal of study. The west and north coasts became fairly well known during the 19th century. The east coast was less easily conquered because of severe ice conditions, which make it hard to approach by ship. In 1806–13 Karl Ludwig Giesecke, a German mineralogist, used the native umiak, or women's boat, to study the southeast coast, and so did Lieut. W. A. Graah in 1829–30. In 1823 Capts. D. Clavering and E. Sabine, following in the steps of Scoresby the year before, carried the survey north to 76° N. and took pendulum observations. In 1876 the Danish Committee for the Geographical and Geological Investigation of Greenland was formed, and since then a consistent program of research has been carried out. The gaps in the southeast coast were filled in by naval expeditions under L. A. Mourier (1879), G. Holm (1883 and 1885) and C. H. Ryder (1891–92), and the rest by Lieut. G. C. Amdrup in the "Antarctica" (1898–1900), the duke of Orléans in the "Belgica" (1905), and Ludvig Mylius-Erichsen in the "Danmark" (1906–08). On the latter expedition long sledge journeys by J. P. Koch and Mylius-Erichsen traced the whole northeast corner of the island, but Mylius-Erichsen and two companions were lost. The last details were filled in in 1909–12 by Ejnar Mikkelsen, who traced the route followed by the dead men and found their records. A series of expeditions, known as the Thule expeditions because they were based on the little trading settlement of Thule in northwest Greenland, did considerable work in north Greenland between 1912 and 1921 under Knud Rasmussen and Lauge Koch.

The Greenland icecap presented a formidable barrier to travelers and at the same time a challenge to both adventurer and scientist. Early attempts to penetrate it from the west coast settlements were made by Edward Whymper in 1867, by Nordenskiöld in 1870 and 1883, by J. A. D. Jensen in 1878, and by Peary in 1886. Peary, the most successful, penetrated 100 mi. from the coast. In 1888 the young Fridtjof Nansen adopted the bold plan of starting from the uninhabited east coast, thus leaving himself no retreat but at the same time avoiding the necessity of retracing his steps. With five companions, using snowshoes and skis, he crossed the icecap from 64° 23′ N. on the east coast to Godthaab on the west. Since then the icecap has been crossed many times, even in its widest parts. Peary was the first to cross the northern part, from Inglefield gulf to Independence fjord in 1892. Other crossings have been made by Knud Rasmussen and by A. de Quervain in 1912, by J. P. Koch in 1913, by Lauge Koch in 1921, and by others.

In 1930–31 three expeditions, simultaneous but independent, maintained stations on the icecap throughout the winter, securing meteorological data vital to the study of world air circulation. They were the British Arctic Air Route expedition led by H. G. Watkins, the German Greenland expedition under Alfred Wegener, and the University of Michigan expedition under W. H. Hobbs. After World War II this work was continued on a larger scale by the French explorer Paul Emile Victor (1947–53) and the British North Greenland expedition under Comdr. C. J. W. Simpson (1952–54). (*See* also GREENLAND.)

The North American Arctic.—By the beginning of the first Polar year in 1882 most of the coast lines of the North American arctic

Far beyond the margins of the shields extensive plains have developed on soft sedimentary rocks. In North America these form the Mackenzie lowlands, Banks and Prince Patrick Islands, and the arctic plains section of northern Alaska; in northern Europe they form the Severnaya Dvina and Pechora plains. In Siberia the Ob delta, its northeastern extension to the Laptev sea, the north Siberian plains, the west Siberian lowlands and farther east the Lena-Kolyma plains (including the New Siberian Islands) have developed on sedimentary rocks. Although there are differences in degree these terrains are essentially flat, occasionally broken by low rock scarps and covered with numerous shallow lakes. The plains are crossed by large rivers which have laid down deep alluvial deposits.

The strongly folded rocks associated with the two periods of mountain building in the arctic form separate physiographic regions. The original mountains of the older, Paleozoic folding were long ago destroyed by erosion but the rocks have been recently elevated and renewed erosion, often by ice, has produced a landscape of plateaus, hills and mountains very similar to the higher parts of the shields. In Ellesmere Island the mountains are nearly 10,000 ft. high. In Peary Land and Vestspitsbergen maximum heights are about 6,000 ft., while in east Spitsbergen and on Novaya Zemlya and Severnaya Zemlya the plateaus rarely exceed 2,000 ft.

The younger group of fold mountains of northeast Siberia and Alaska are generally higher. Peaks of 10,000 ft. are found in the Cherski range, 15,000 ft. in Kamchatka and even higher in southern Alaska. Characteristic of this physiographic division are the wide intermontane basins often drained by large rivers such as the Yukon and Kolyma.

Throughout the arctic, excluding a few maritime areas, the winter cold is so intense that the ground remains permanently frozen except for a shallow upper zone, called the active layer, that thaws during the summer. This permanently frozen ground (permafrost) covers nearly one-quarter of the earth's surface. In northern Alaska and Canada scattered observations suggest that permafrost is 800–1,500 ft. deep; it is generally deeper in northern Siberia. The deepest known permafrost is at Nordvik, northern Siberia, where it is 2,000 ft. The depth of the permafrost depends on the site, climate, vegetation, and the recent history of the area, particularly whether it was covered by sea or glacier ice. The very deep permafrost was probably formed in unglaciated areas during the Ice Ages. To the south in the subarctic the permafrost thins and eventually becomes discontinuous, although it may locally still be 200–400 ft. thick; along its southern boundary permafrost survives under peat and bogs. In areas of continuous permafrost the active layer may be many feet thick in sandy well-drained soils with little vegetation; it is usually less than six inches thick beneath peat.

Permafrost occurs in both bedrock and surface deposits. It has little effect on rock but in fine-grained, unconsolidated sediments, particularly silts, lenses of ice, called ground ice, grow by migration of water and in extreme cases half the volume of arctic silts may be ice. Ground ice is often exposed in river banks and sea cliffs, when it may be 20 to 30 ft. thick. In northern Siberia fossil ice has been reported up to 200 ft. thick, although in these cases it may be glacier or lake ice that has subsequently been buried under river deposits. If ground ice melts, due to a change in climate, pits are formed in the ground and quickly fill with water to form lakes and ponds. In their frozen state the silts have considerable strength, but if they thaw they change in volume, lose their strength and may turn to mud. Variations in volume and bearing capacity of the ground due to changes in the permafrost constitute one of the major problems in arctic construction.

Permafrost totally inhibits underground drainage. Consequently shallow lakes are numerous over large areas of the arctic, and everywhere in early summer there is a wet period before the saturated upper layers of the ground dry out. During the summer waterlogged active layers on slopes may slide downhill over the frozen ground, a phenomenon known as solifluction. It is ubiquitous in the arctic but is particularly intense where the soils are fine-grained, as in the coastal plain of north Alaska, or where the precipitation is heavy, as on Bear Island (Bjørnøya) in the Norwegian sea. The effect of solifluction is to grade slopes so that long, smooth profiles are common; slopes are normally covered with vegetation, but if the soil movement is too fast plants may not be able to survive. Under these conditions the surface material is often graded, with narrow strips of pebbles and boulders separated by broader strips of finer particles.

Many soils in northern areas show distinctive patterns produced by complex processes of freezing and thawing, which cause frost heaving and sorting of debris; although permafrost is not essential to these formations, it is usually present. There are many different types of patterned ground. In some, coarser material, pebbles and boulders form polygonal nets with the finer materials concentrated in the centre. When sorting is widely spaced stone circles develop. Another kind of pattern, formed in sands and muds, is outlined by frost-crack fissures or strips of vegetation. Individual polygons vary from about 1 ft. to over 300 ft. in diameter. Mounds due to frost heaving in the soil are also widespread. They grow rapidly, disrupting leveled fields in a few years.

Many exposed rock surfaces in the arctic have been quickly broken up by frost action so that much rock is buried under a cover of angular shattered boulders. These mantles are known as *felsenmeer* (sea of rock) and are found principally on arctic uplands. Their continuity and depth varies with climate, vegetation and rock type but they may be as much as 12 ft. deep. *Felsenmeer* are especially well developed on basalts and are consequently numerous on the Icelandic plateaus. They also develop quickly on sedimentary rocks and are widespread in the Canadian arctic, all the way down to sea level.

2. Glaciation.—Although the arctic is commonly thought to be largely ice-covered, less than two-fifths of its land surface in fact supports permanent ice. The remainder is ice-free either because of relatively warm temperatures or scant snowfall. Glaciers are formed when the annual accumulation of snow, rime, and other forms of solid precipitation exceeds that removed by summer melting. The excess snow is converted slowly into glacier ice, the rate depending on the temperature and annual accumulation. In the arctic, where most glaciers have temperatures far below freezing point, the snow changes into ice slowly. In northwest Greenland a hole 1,400 ft. deep was made into the ice sheet

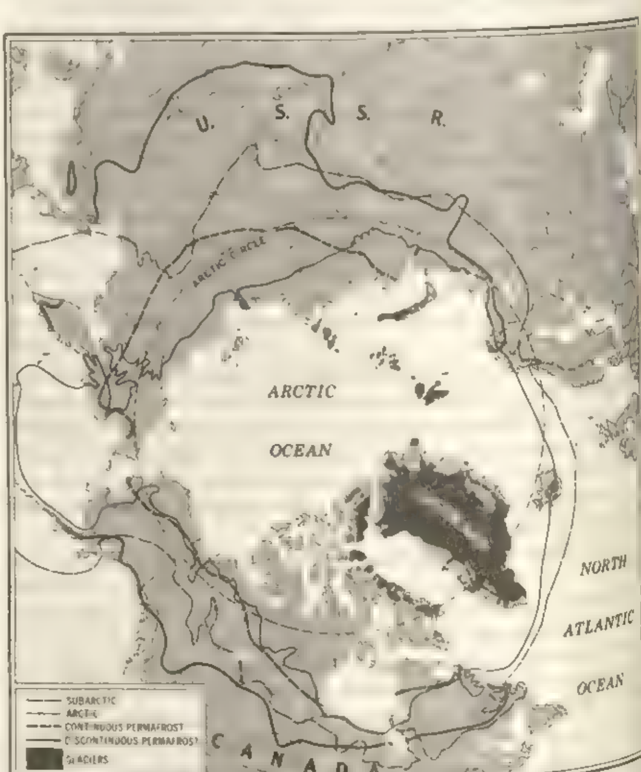

FIG. 3.—DIVISION OF SUBARCTIC AND ARCTIC REGIONS SHOWING DISTRIBUTION OF PERMAFROST AND GLACIERS

without reaching glacier ice. The hole showed over 800 annual snow layers, from which it was possible to determine precipitation changes for the last eight centuries.

The altitude at which ice accumulates over a period of years is known as the glaciation limit and is roughly equivalent to the snow line. It is often very variable within short distances. On Baffin Island the glaciation limit is a little over 2,000 ft. above sea level in the extreme southeast, rising to over 4,500 ft. in the Penny icecap 300 mi. to the north and descending to about 2,000 ft. in the north of the island. In Greenland the limit is at about 6,000 ft. in the south and decreases irregularly to about 3,000 ft. in the north. Nowhere in the arctic regions is the glaciation limit at sea level; glaciers found close to the sea have all flowed down from higher levels. The domes of some arctic icecaps are below the glaciation limit but they continue to survive because of their low internal temperatures; the winter snowfall melts completely but refreezes in contact with the cold ice. This phenomenon, first observed on the Barnes icecap of Baffin Island, is now known to be widespread in the high arctic.

The glaciers of the north polar regions can be divided into two groups depending on the source of their snow; the larger group is around the Atlantic and the smaller around the Pacific ocean. The largest ice mass, the Greenland inland ice, is part of the first group and is the largest glacier in the northern hemisphere. It extends 1,570 mi. from north to south, has a maximum width of 600 mi., an average thickness of about 5,000 ft., and covers an area of approximately 700,000 sq.mi., nearly 85% of Greenland. It is contained within an elongated saucer-shaped depression, the sides of which are mountains (called nunataks) that rise through the margins of the ice. In the centre the base of the ice is more than 1,000 ft. and may be as much as one mile below sea level. This discovery has led to the suggestion that Greenland is an archipelago rather than one large island. Although this might be so for a short time if the ice melted, the land would soon rise when the ice mass disappeared, forming a plateau at about 3,000 ft. The crest of the inland ice, which exceeds 10,000 ft. above sea level midway between the east and west coasts in the northern part of the island, is displaced to the east in the south. In the centre the surface of the ice is undulating and is frequently covered with wind-drifted formations of snow called *sastrugi*. The icecap slopes off to the sides, reaching the sea in a 240-mi. front along Melville bay in the west and along two smaller stretches in the northeast. Elsewhere huge outlet glaciers flow down to the sea. All combine to produce the vast numbers of icebergs that bar the coast of Greenland and are carried south in the Labrador current to the Atlantic shipping lanes. In summer the margins of the inland ice are covered with soft, sticky, granular snow. Three main ice-free areas are found in Greenland, in the southwest, where the inland ice is separated by 100 mi. from Davis strait; north of Scoresby sound in the east; and in Peary Land in the north.

In arctic Canada the permanent ice is restricted, with few exceptions, to the northeast, a result of the greater relief and precipitation around Baffin bay and Davis strait. The most southerly ice is found in the Torngat mountains of northern Labrador, where there are small cirque glaciers. Immediately north of Hudson strait on the plateau south of Frobisher bay there are two small icecaps. Larger icecaps and highland ice (through which mountains project) are present farther north along the east of Baffin Island and on Bylot Island; only the Barnes icecap lies west of the coastal group. North of Lancaster sound the ice is more extensive and large parts of Devon, Ellesmere and Axel Heiberg islands are glacierized. In many ways these icecaps are small versions of the Greenland inland ice, with a central dome-shaped section and outlet glaciers pouring down through the mountains toward the sea. The icecap on Meighen Island, the most westerly of the group, is an exception, as it is circular in shape and lies on low ground. Except for three small, unexplored glaciers on Melville Island there are no glaciers in the Canadian western arctic. Only a few of the Canadian glaciers reach the sea and form icebergs. In the Arctic ocean off northern Ellesmere Island there is an area of floating shelf ice that may at one time have been joined by glaciers, but the glaciers no longer reach the sea. This shelf ice has been the principal source of the ice islands of the Arctic ocean.

Other glaciers are found north and east of the Atlantic ocean and its continuation in the Norwegian and Barents seas. Iceland has five major icecaps, the largest of which, Vatnajökull, covers 3,400 sq.mi. All have small outlet glaciers although none reaches the sea. The icecaps owe their survival to extremely heavy precipitation. The western part of Vatnajökull buries a volcano, Grímsvötn, which erupts every six to ten years; the heat of the eruption forms a vast subglacial lake which bursts in great floods over the margins of the glacier.

North of Iceland, Jan Mayen Island supports a glacier on the volcano Mt. Beerenberg. The glaciers of Svalbard cover about 90% of the land. On the largest island, Vestspitsbergen, the plateaus are covered with highland ice from which outlet glaciers reach the sea; there are also numerous independent valley and cirque glaciers. North East Land, the second largest island, supports two icecaps on its plateaus. On the east side of the Atlantic ocean precipitation is heavy over the Scandinavian highlands, but temperatures are also high and the total area of ice is only about 2,000 sq.mi., a small part of which is in north Sweden and the remainder in Norway. To the northeast, beyond the Barents sea, precipitation is far less but the summer is shorter and permanent ice is widespread.

Farthest north in this group are the islands of the Franz Josef archipelago. Although at no point are they higher than 2,500 ft., probably more than 90% of their area is covered with ice; some of the smaller islands are completely buried by glaciers. The southern island of Novaya Zemlya supports a few small glaciers; on the northern island they become more numerous and the northern four-fifths of the island is ice-covered, with large outlet glaciers reaching the sea.

Weather disturbances penetrate into the Kara sea beyond Novaya Zemlya and produce sufficient snow for ice to form on Severnaya Zemlya (North Land). There are four major and many minor islands in the group. Although they are low lying, consisting primarily of plateaus less than 2,000 ft. high, all the larger islands have icecaps that cover rather less than half the total area. Outlet glaciers reach the sea and are an occasional source of icebergs. Elsewhere the Russian northern areas are remarkably free of ice. Small cirque glaciers are found in the Ural mountains and the mountains of northeast Siberia. Not until the Pacific is approached do the mountains again have alpine glaciers, another indication of the importance of moisture for the development of glaciers.

The glaciers around the North Pacific are concentrated in Alaska. Although the glaciers of southern Alaska are alpine rather than arctic, they are among the finest mountain glaciers in the world. All types of ice are present, from small valley glaciers to highland ice almost burying mountain ranges, with piedmont glaciers spreading out in the lowlands. The largest ice centres are around the Fairweather range, the St. Elias mountains and the Chugach mountains. Glaciers in these areas include the Hubbard, 90 mi. long, intermontane glaciers such as the Seward and piedmont glaciers such as the Malaspina. Smaller glaciers also occur inland on the Alaska range and in the Brooks range of northern Alaska; there is more ice farther east in the Romanzof mountains, where one glacier, the Okailak, is ten miles long. There are a few small glaciers in the Aleutian range and ice is found infrequently on the Aleutian Islands.

The overwhelming majority of arctic glaciers, except for the Greenland inland ice, are in retreat and many areas are more ice-free than ever before in the historical period. In Iceland, where glacier movements are well-recorded, the ice appears to have been restricted from the 10th until about the 14th century. The ice then advanced, reaching a maximum about 1750. A second advance followed a minor retreat, culminating about 1850, and a major retreat set in about 1890. The recession was slow at first but by the 1930s it was generally rapid and has continued since.

(J. B. Bd.)

3. Arctic Ocean.—The Arctic ocean consists of the North Polar sea (sometimes called the Arctic sea) (to approximately 80°

N.) and associated waters such as the Greenland, Norwegian, Barents, Kara and Laptev seas, Baffin bay and the waters of the Canadian arctic archipelago. The total area of this system is estimated at 5,427,000 sq.mi. Hudson bay and Hudson strait add about 480,000 more and the Bering sea a further 885,000.

The North Polar sea contains two basins, each over 13,000 ft. in depth, separated by a ridge or system of ridges, one of which, the Lomonosov ridge, extends from the north of Greenland to the New Siberian Islands. The Marvin ridge lies a little to the west of the Lomonosov and parallel to it, in the region between the pole and Ellesmere Island. These enormous submarine features rise from the floor depth to between 3,300 and 4,500 ft. below the surface. The Greenland and Norwegian seas, each somewhat over 9,800 ft. in depth, are separated by a ridge about 6,500 ft. deep, and the northern of the two (Greenland sea) is separated from the North Polar sea by the Nansen ridge about 5,000 ft. deep. The southern boundary of the Norwegian sea is the Wyville-Thompson ridge, extending from Scotland to Iceland and with an extension between Iceland and east Greenland. A similar ridge reaches across Davis strait, west of Greenland, forming the southern boundary of Baffin bay. This extensive southern ridge system, only about 2,000 ft. below the surface, effectively divides the Arctic ocean system from the North Atlantic proper.

Baffin bay has a maximum depth of just over 6,500 ft. and the waters between the Canadian arctic islands are much shallower, of the order of 1,600 ft. or less. Hudson bay has a general floor depth of only about 650 ft. and Hudson strait has a depth at its eastern end of a little over 1,300 ft. The continental shelf off the north Siberian coast is up to 435 mi. (700 km.) wide; elsewhere it is quite narrow, with the exception of Hudson bay and Foxe basin, which are of shelf depths entirely.

The water masses in this system are (1) the Arctic water; (2) the Atlantic water; (3) the Pacific water; and (4) the deep water of the several basins. The coastal water and upper layer of the North Polar sea are strongly influenced by drainage from the land.

The Arctic water is formed in the North Polar sea from three sources—Atlantic water, drainage from the land, and water from the melting of ice. The result is a layer of water of generally negative temperatures (centigrade) and salinities below 34 grams of salt per kilogram of sea water ($34^0/_{00}$). This layer is generally between 300 and 900 ft. thick. Below it is a thicker layer of Atlantic water, entering the North Polar sea between Spitsbergen and Greenland, with positive temperatures up to 3° C. (37.4° F.) but generally much lower, 0.5° C. (33° F.) to 1.5° C. (35.7° F.). This layer reaches down to a depth of 2,300–2,600 ft., below which is the mass of Arctic bottom water extending to floor depths, again with negative temperatures and salinities close to, but just below, $35^0/_{00}$. Recent research seemed to show that these three layers are not so distinct as formerly thought.

The currents in the Arctic ocean system form a pattern of inflow to, and outflow from, the North Polar sea, which is fairly stable and which allows the whole area to be divided into "arctic" and "subarctic" marine zones (which have little in common with the arctic and subarctic zones on land). By far the greatest inflow is the Atlantic drift water described above, which comes to lie beneath the Arctic layer. A much smaller inflow, about one-tenth in volume, passes north through Bering strait from the Pacific ocean. Allowing for evaporation from the surface, and for the land drainage, the corresponding outflow is shared between the East Greenland current and the Canadian current. There is also a small outflow through Fury and Hecla strait into Foxe basin. The Canadian current flows down the east coast of Baffin Island, drawing its water from the channels between the arctic islands. At the level of Hudson strait it is joined by contributions from West Greenland and from Hudson strait and forms the great Labrador current, which meets Atlantic drift water east and south of Newfoundland. The West Greenland current, flowing north and northwest, is formed by East Greenland current water rounding Cape Farewell and by Atlantic water from the Irminger current which strikes west from southwest Iceland toward southeast Greenland.

In both physical and biological terms, the northern marine environments can conveniently and realistically be divided into arctic, subarctic and boreal, on the criterion of the presence or absence of Arctic water from the upper layer of the North Polar sea. The arctic zone is that marine area lying north of the influence of Atlantic or Pacific water, in the upper layers; the subarctic zone is the area in which Arctic and non-Arctic (Atlantic or Pacific) water are mixed or are found in close relation; the boreal zone is the Atlantic and Pacific area south of the southern extension of the influence of Arctic water, whether mixed or not. The boreal zone extends southward to whatever limit may be conveniently set upon it. In general, the most productive parts of the waters, in terms of living substance, are the subarctic zone and the northern part of the boreal.

Surface temperatures in the Arctic ocean system are always low, seldom rising above 4° or 5° C. (39° to 41° F.) even at the height of summer. Wherever there is ice the temperatures are close to 0° C. (32° F.) or lower (sea water of salinity $34^0/_{00}$ freezes at about −1.8° C.). There is an area known as the "north water," in northern Baffin bay or southern Smith sound, which remains unfrozen all winter, and in this region the summer temperatures are often above 5° C. Hudson bay, which in summer is subject to considerable surface dilution from land drainage, can be as warm as 10° C. (50° F.) in its southern part for a brief period.

The North Polar sea itself is partly covered with sea ice at all times, the extent ranging from about $\frac{1}{10}$ cover to $\frac{9}{10}$ or $\frac{10}{10}$ cover, depending on season and locality. One-year-old ice is seldom more than 7 to 8 ft. thick but rafted ice can extend down to 40 ft. or even more. After one winter sea ice has lost its salt by a leaching process, and therefore when it melts it dilutes the surface layer. The East Greenland and Canadian currents carry both sea ice and icebergs, the latter from the Greenland icecap, southward to various latitudes but normally not farther than Newfoundland. (M. J. D.)

4. Climate.—The climates of northern lands are highly varied. It has been customary to divide them into two large groups corresponding to the climate of icecaps, in which no mean monthly temperature exceeds 32° F., and the tundra climates, with at least one month above 32° F. but no month above 50° F. A more satisfactory division is to classify them as polar maritime climates, located principally around the Atlantic and Pacific oceans, in which winter temperatures are rarely extremely low and snowfall is high; and the polar continental climates, as in north Alaska, Canada and Siberia, where winters are very cold and snowfall is generally light. Included in the polar continental climate type is the Canadian arctic archipelago, which is influenced only slightly by the sea in winter because of thick ice. In addition to these two climates there are smaller transitional zones, limited areas of "ice" climates and, adjacent to the arctic, the subarctic climates.

Although the polar continental climates have low winter temperatures they are not as cold as the subarctic. The lowest temperatures ever recorded in the northern hemisphere were measured in the subarctic of northeast Siberia, the coldest area being around Oymyakon. In North America a temperature of −81° F. was observed at Snag, Yukon territory. Temperatures below −80° F. have been recorded on the Greenland icecap. Colder temperatures have not been found in the tundra regions because generally windier conditions prevail.

Winter sets in toward the end of August in the far north and about a month later near the tree line. The temperature continues to drop rapidly until about December. January, February and early March have uniform conditions with mean temperatures about −35° F. in the central Siberian arctic and −20° to −30° F in North America. The lowest extreme temperatures in the winter are between −50° and −65° F. A better indication of low temperatures as they affect man is given by the windchill, a measurement of the cooling power of the atmosphere on human skin. It reaches a maximum north of Hudson bay, where strong and persistent northwest winds, typical of the Canadian eastern arctic, are combined with low air temperatures. This area is stormy in winter with moderately high snowfall (50–100 in.), rapidly changing temperatures, and even occasional rain. Elsewhere the winter continental climate is quiet, with long periods of clear sky and

low snowfall. Visibility may be poor locally if there are open channels of water in the sea ice and is universally reduced when the wind blows drifting snow. The lowest snowfall is in the northern Canadian islands and in north Greenland, where the total annual precipitation is frequently less than four inches of water.

Winter in the maritime arctic (the Aleutians, coastal southwest Greenland, Iceland and the European arctic) is a period of storminess, high winds, heavy precipitation either in the form of snow or rain (the latter at sea level) and moderate temperatures. The coldest month is rarely below 20° F. and extremely low temperatures are unknown.

Summer temperatures are more uniform across the whole of the arctic. On the southern margin the monthly mean temperature reaches 50° F. and in continental positions short spells of hot weather with temperatures in the 80s, continuous sunshine and calm weather are not uncommon; such weather often ends with thunderstorms. In the maritime climates, along the coasts, and on the northern islands when there is open water in the sea ice, the summer is relatively cool. In the south the temperatures are about 45° F. decreasing north to 40° F. or less; a maximum of 60° F. is hardly ever reached. Fog and low clouds are widespread and at this time of the year these areas are the cloudiest in the world. In areas that experience continental winters precipitation is heaviest during the summer months; light rain and snow showers are frequent but the average fall is rarely high. The summer is everywhere a time of sudden changes. Calm, clear weather with sunshine and temperatures of about 50° F. will be followed by sudden winds, often causing a temperature drop of 20° to 30° and accompanied by cloud and fog. These changes are often local and in the next valley or at the head of a fjord fine weather may continue.

The frost-free and growing periods are short throughout the arctic. For the most part there is no true frost-free period, frost and some snow having been recorded in every month. At a few places near the tree line, notably in the Canadian western arctic, the frost-free period may be the same as the less favourable parts of the prairies.

The polar basin has a winter similar to that of northern Alaska and Siberia with long, clear, cold periods and occasional storms, accompanied by a brief rise in temperature. The summers are cloudy and foggy, winter snow melts off the pack ice and the mean temperature rises to about 35° F. The climate of Svalbard and Novaya Zemlya is transitional between maritime and continental conditions with a cool rather than cold winter (mean temperature 0°).

The only extensive ice climate in the northern hemisphere is that of Greenland. In the south the icecap has maritime characteristics with heavy precipitation, mainly as snow from passing cyclone disturbances. In the north conditions are quieter and the snowfall consequently less. Although the air temperature may sometimes rise to 32° F. the mean temperature remains well below.

The polar climates have changed noticeably during the 20th century, the climatic amelioration that produced the retreat of the glaciers having been widely felt. Sea ice around Iceland, Svalbard and southwest Greenland has decreased in extent. The pack ice in the Arctic ocean is thinner. Birds, animals and especially fish have appeared farther north than before; in Greenland this led to a complete change in the economy, as its traditional dependence on seals gave place to dependence on fishing. Atlantic cod, in particular, have appeared in increasing numbers and are caught north of the 70th parallel. The cod, unlike the seal, does not provide fuel and clothing as well as food; consequently the economy has changed from an extraordinarily self-sufficient one to one based on cash and international trade. With the warming of the climate sheep farming also has been introduced successfully in the southern part of Greenland.

The main changes in the climate result from increases in air and sea temperatures. The increases in air temperatures have been greatest in winter around the North Atlantic ocean centred on Svalbard but are found at all seasons and in all areas. The warming began at the beginning of the 20th century, reached a maximum in the 1930s and declined briefly in many localities in the early 1940s, only to increase again subsequently. The basic cause is not known, although it results directly from increased penetration of southerly winds into the polar regions.

5. Vegetation.—Two main vegetation zones are found in the polar lands. In the south is the subarctic, formed by the northern subzones of the circumpolar boreal forest. To the north is the arctic proper, where the vegetation is generally referred to as tundra (*q.v.*), from the Finnish word for an open rolling plain; in North America the descriptive term Barren Grounds is frequently applied. The two zones are separated by the tree line. This is by definition the absolute northern limit of treelike species, although even beyond it the same species may be found in low shrubs and dwarfed forms. The tree line is composed of different species. In Alaska and northwestern Canada white spruce is dominant while in Labrador-Quebec it is black spruce and occasionally larch. By contrast, in northern Europe and Siberia the tree line is formed by larch, pine and fir. The tree line is related to summer warmth, which may be correlated closely with tree growth. Alexander Supan found good coincidence between the 50° F. July isotherm and the tree line, a figure later modified by Otto Nordenskjöld to allow for spring temperatures.

In North America the tree line extends from the shores of Bering strait along the Brooks range of Alaska to the Mackenzie delta and then curves southeastward across the Northwest Territories to Churchill and James bay. East of Hudson bay it crosses northern Quebec to Ungava bay and then continues into Labrador. In western Scandinavia, the tree line is within a few miles of the sea; it curves east and crosses northern Siberia 50–150 mi. S. of the Arctic ocean.

Arctic plants have to contend with a harsh environment including low temperatures, continuous daylight in summer, poor soil and permanently frozen ground, and in many areas strong, dry winds and blowing snow. The species that survive are few and are frequently dwarfed. Many plants grow in compact cushions for maximum protection from the climate. The growing season is so short that annuals are rare and perennials reproduce asexually by shoots or runners. Even so, arctic plants have a rapid seasonal life cycle. Spring growth often begins when snow is on the ground and there are still heavy frosts; the flower and seed stages follow in a period as short as six weeks. The sudden blooming of flowers is spectacular, particularly along the southern edges of the tundra, and for a short time in July the Barren Grounds are covered with a mass of flowers. The species vary but typical are those in the western American arctic, which include the blue-spiked lupine, wild crocus, mountain avens, arctic poppy and saxifrage. By late August the cycle is complete and the plants are awaiting winter.

At first sight many parts of the arctic are rocky wastes without soil or vegetation. Closer inspection shows that some plant life is always present and even on permanent ice there are often algae. The bare rock surfaces support thin brown, black, or gray crustaceous lichens which swell and become soft when wet; some of the larger black lichens are edible and are generally known as "rock tripe." In the past these lichens have been used by starving explorers for food. Higher plants grow in rock crevices and succeed in forming tussocks on patches of soil. Close to the southern edge of the arctic dwarf shrubs are found in protected sites on these rock deserts.

Tundra areas have a continuous cover of vegetation and many different tundra associations (plant communities) may be recognized. In the drier and better-drained parts, heath tundra is dominant, made up of a carpet of lichens and mosses with isolated flowering plants. In some areas, notably west of Hudson bay, a similar environment results in tundra grassland. When there is more moisture, sedges and grasses become important and form tussock or hillock tundra; willow and dwarf birch may be found between the individual mounds. This type of tundra reaches its greatest development on the north Alaskan coastal plain.

In the warmer parts of the arctic woody dwarf shrubs, willow, birch, juniper and, locally, alder are profuse. In the southern arctic, several of these shrubs modify the heath tundra, and low scrub woods may be quite extensive. On sheltered south-facing slopes, tall thickets of willow, birch and alder develop and, under

optimum conditions, these bushlike "trees" may be more than ten feet high. This type of vegetation is common in all circumpolar lands close to the tree line and is conspicuous in the inner fjords of southwest Greenland and in northern Iceland. The bushes may be used locally for fuel or for mats in the western Canadian arctic, and in former times were used by Eskimos for arrow shafts. The wood is unsuitable for bows, spears, or boat building; for these purposes the Eskimos either had to travel to the tree line or search for driftwood that was widely distributed along the arctic coasts.

The tundra vegetation is the source of food for the northern grazing mammals but contains few foods of direct value to man. Berries are found throughout the southern arctic. Most widely used by the native population has been the black crowberry (*Empetrum nigrum*), eaten either raw or mixed with animal oil. Europeans have found the cloudberry (*Rubus chamaemorus*), bilberry (*Vaccinium uliginosum*), and mountain cranberry (*V. vitis-idaea minus*) more palatable. Mushrooms are widely distributed and can be used for a welcome change of diet.

South of the tree line is the subarctic forest-tundra. Its bare wind-swept ridges are covered with tundra associations while in the sheltered valleys there are woodlands which may become continuous near large rivers and, if the rivers flow north, may project many miles into the Barren Grounds. These areas, known as *galeria* forests, are found along the Coppermine river of Canada and are frequent along the north Siberian rivers. The woods contain the same coniferous species as form the tree line, together with several broad-leaved species, notably birch.

Arctic soils are closely related to vegetation. Unlike soils farther south they rarely develop strong zonal characteristics. By far the commonest are the tundra soils, which are circumpolar in distribution. They are badly drained and strongly acid and have a variable, undecomposed organic layer over mineral horizons. Some of the drier heath and grassland tundras overlie arctic brown soils which have a dark-brown upper horizon with gray and yellowish-brown lower horizons. The active layer in the permafrost is normally deep in them. (J. B. Bd.)

6. Animal Life.—Compared with that of warmer parts, animal life in the arctic is poor in species but often rich in individual numbers. This is generally considered to be the result of at least two factors—the comparative novelty of polar glacial climates, allowing only a limited time for adaptation since their onset; and the much lesser variety of habitats available for colonization in the north as compared with the lower latitudes.

The fauna considered in this section is that of the true arctic zone only. On the land, this is the zone north of the tree line; in the sea, the area in which the upper water is of North Polar sea origin (see *Arctic Ocean*, above), without admixture of Atlantic or Pacific water. This excludes most of the west Greenland waters and the waters of west and southern Iceland, the Faeroe Islands and Norway; it also excludes the Labrador sea and the waters of the Labrador coast south of Hudson strait.

Animals of the Land and Fresh Water.—The typical and best known arctic land mammals and birds are those highly successful forms, most of them circumpolar in distribution, which survived the Pleistocene glaciations probably both south and north of the ice sheets, south along the ice perimeter and north in ice-free refuges such as northern Alaska, the Bering strait (then dry land), and northeast Siberia, certain of the Canadian arctic islands and probably northernmost Greenland. These include the polar bear (as much a marine as a terrestrial animal), caribou, arctic wolf, arctic fox, arctic weasel, arctic hare, and the brown and collared lemmings, ptarmigan, gyrfalcon and snowy owl. These, together with the vegetation that feeds the lemming, ptarmigan and caribou, form a tight ecological system which is virtually self-sufficient. During the winter, and during periods of low lemming population which occur every three to five years, the carnivores make some use of seashore life and (through the agency of the polar bear) of seal and fish. In extreme starvation conditions there is a tendency for the snowy owls and gyrfalcons to go south in winter and for the foxes and wolves to become scavengers.

The caribou is a migrant, but only between the arctic tundra and the conifer (subarctic) zone to the south, and there are far northern groups of caribou whose migrations are more restricted. The musk ox is a special case. Now restricted to the North American arctic (including north Greenland), it was formerly more widespread, and is probably to be regarded as a "refugee" species, chased into the far north and on the defensive in the evolutionary sense.

Hibernation is not a phenomenon of the arctic because frost-free refuges are not available; all the nonmigrant, warm-blooded animals therefore remain active all winter. Any incipient hibernation, shown for instance by the arctic ground squirrel, proves abortive, the animals shivering themselves awake after only a few days.

Most of the birds of the arctic zone are migrants, coming from wintering grounds as far away as the southern U.S., Central America, Brazil, or even the subantarctic zone. By migration the birds obtain the advantage of the long northern summer days and of the high productive capacity of plant foods in the short but intense growing season. There is increasing evidence that food is not a limiting factor on summer bird populations in the arctic, except in the case of strictly predaceous species during years of scarcity of prey. Typical land and fresh-water birds of the arctic zone are the redpoll, Lapland longspur, snowbird, wheatear, pipit, certain plovers and sandpipers, loons, rock ptarmigans, ducks and geese.

There are no reptiles in the arctic zone, owing to the absence of frost-free winter refuges, but one amphibian, the wood frog, does penetrate just north of the tree line in arctic Canada. It breeds in July and early August in ponds and small lakes, and spends the rest of the year buried in the mud at the bottom. The mud does not freeze and the frogs are able to breathe through the skin, which the reptiles cannot do.

Fresh-water fishes in the arctic are represented by a few species only: whitefish, lake trout and speckled trout, arctic grayling, two species of stickleback, the Alaskan blackfish and the arctic char. In some regions the burbot, northern pike and Atlantic salmon penetrate north of the tree line.

The invertebrate fauna of the land and fresh water consists largely of insects, including the chief scourges of the north, mosquitoes and black flies. Among the most northern navigators are certain spiders, which winter even in northern Ellesmere Island. Crustacea are represented by the branchiopods, which form an important part of arctic pond life, and by the copepods. There is in addition a very considerable number of smaller species belonging to many phyla.

Animals of the Sea.—In terms of the mass of living matter produced, the seas are by far the richer part of the arctic, and it is no accident that the Eskimo economy has traditionally been marine. The bowhead or Greenland whale was once hunted keenly by both white men and Eskimos; almost extinct at the beginning of the 20th century, it is now coming back in some strength. The sperm whale is also frequently seen. The commonest whales are of the porpoise group, the beluga or white whale, the narwhal and the killer whale, the last-named being possibly the fiercest and least friendly mammal alive. The pinnipeds are represented by the walrus, now recognized as two species, Pacific and Atlantic, which between them form an almost complete circumpolar ring; and by the hair seals, including the bearded seal or squareflipper, the little ringed seal, the northernmost of the harbour seal populations, the ribbon seal (a North Pacific rather than arctic form) and the migrant harp and hooded seals, both of which are North Atlantic species with summer feeding areas in eastern arctic Canada, Greenland and eastward.

The sea birds are represented by the auk family (murres, guillemots, auklets and little auk), the sea ducks (eider, scoter, old squaw), the gulls and terns (especially the glaucous and glaucous-winged gulls, many of the herring gull group of species, Sabine's gull, and the common and arctic terns), the jaegers (parasitic, pomarine and long-tailed), and the waders (sandpipers, etc.). One of the petrel group, the fulmar, breeds on certain arctic cliffs. These are all migrant species which fly south in the fall. The arctic tern makes a remarkable migration to subantarctic waters.

It is characteristic of arctic waters (as opposed to subarctic mixed waters) that they are poor in fish species. In the subarctic

the fishes are the dominant larger forms but the mammals dominate in the arctic. A few species of sculpins, eelpouts, snake blennies, sand launces and lumpsuckers are found in the arctic zone, but they are comparatively insignificant ecologically. Only three species can be said to be significant—the arctic cod, a small cod often found abundantly at the surface in the North Polar sea and also further south; the arctic char, an anadromous species related to the speckled trout, which moves upstream to spawn and spends perhaps two months or less in the sea per year; and the Greenland shark, which grows to a length of about 15 to 20 ft. and is common in the far north, especially off bold rocky shores in deep water.

The invertebrate life is well developed and sometimes astonishingly abundant, but it forms too specialized a topic to be discussed here. The polar basin itself, although much poorer in planktonic life than the waters immediately to the south largely owing to ice cover, nevertheless carries a comparatively large production associated with the ice itself, in the form of Crustacea which appear to feed upon organic material occluded or otherwise attached to the ice surfaces. (M. J. D.)

III. PEOPLES OF THE ARCTIC

1. Northern America.—All of the American arctic and much of the subarctic is occupied by a single people, the Eskimo (*q.v.*). With their territory extending over more than 6,000 mi. of coast line from south Alaska to east Greenland and Labrador, the Eskimos have the greatest linear distribution of any people in the world, though they number only about 50,000 individuals. Throughout this enormous territory there is a remarkable uniformity of language, culture and to some extent physical type. To the south of the Eskimos are two Indian groups, the Algonkian Cree and Naskapi of central and eastern Canada and the Athapaskans of interior Alaska and Canada, the northernmost of whom are the Koyukon, Tanana, Kutchin, Hare, Bear Lake, Dogrib, Yellowknife, and Chipewyan.

2. Northern Asia.—The peoples of arctic Asia, like the Eskimos and American Indians, are physically Mongoloid. On the other hand, northern Eurasia is an area of marked linguistic diversity. The lands bordering the Arctic ocean from Bering strait westward to Scandinavia are inhabited by peoples speaking many languages falling into no less than six separate linguistic stocks—Eskimo, Paleo-Siberian, Altaic, Ket, Uralic and Indo-European. The presence of numerous languages in arctic Eurasia shows that the region has been penetrated repeatedly by different groups of people in the past; the contrasting situation of a single language—Eskimo—on the arctic coasts of America shows that no such penetration occurred there. The primitive tribes of northern Eurasia have been subjected to strong Russian influence and their mode of life has changed considerably, especially in the Soviet period.

Eskimos.—The Siberian Eskimos or Yuit live in permanent villages on the east coast of the Chukchi peninsula facing Bering strait. They are related to the Yuit of St. Lawrence Island and are primarily sea mammal hunters. Archaeological evidence indicates that the Siberian Eskimos are not relatively recent migrants from Alaska, as was once thought, but the remnant of an ancient Eskimo population ancestral to that of Alaska.

Paleo-Siberians.—A number of primitive peoples in northeastern Siberia are referred to collectively as Paleo-Siberians on the assumption that they are the original inhabitants of the area, pushed there by pressure of Neo-Siberian (Altaic) peoples moving up from the south. There are four groups of Paleo-Siberians, each speaking its own language:

(1) The Gilyaks or Nivkhi who occupy the lower Amur river and Sakhalin Island and who live by hunting, fishing, sealing, trapping, and more recently cattle breeding and farming.

(2) The Chukchi group, with a total population of about 20,000 and by far the largest of the four groups. It comprises the Chukchi or Luorawetlan of extreme northeast Siberia; the Koryak or Koriaki, occupying the northern part of the Kamchatka peninsula and adjacent areas to the north; and the Kamchadals or Itelmen of the Kamchatka peninsula. The Chukchi and Koryak are divided into nomadic and sedentary groups, the former roaming the interior with their reindeer herds, the latter living in permanent settlements along the coast where they hunt sea mammals. The Kamchadals live mostly by fishing.

(3) The Yukaghir group, living between the Yana and Indigirka rivers and along the tributaries of the upper Kolyma, and including the Yukaghir or Odul and the closely related Chuvantsy or Etel and Omok or Omoki. Their language is probably related to Uralic.

(4) The Yeniseian group—hunters, fishers, reindeer breeders—living mostly along the Turukhan and middle Yenisei rivers, comprising the Kets, formerly known as the Yenisei Ostyak, and three small extinct groups, the Kots, Asans, and Arins.

Tungus.—More widely distributed than any other Siberian people, the Tungus (Evenki) extend south from the Arctic ocean to Manchuria and west from the Okhotsk sea to the Yenisei river. Numbering about 62,000, they live as reindeer herders and hunters in the north and as cattle breeders or farmers in the south. The Tungus language is one of the major divisions (Tungus-Manchu)

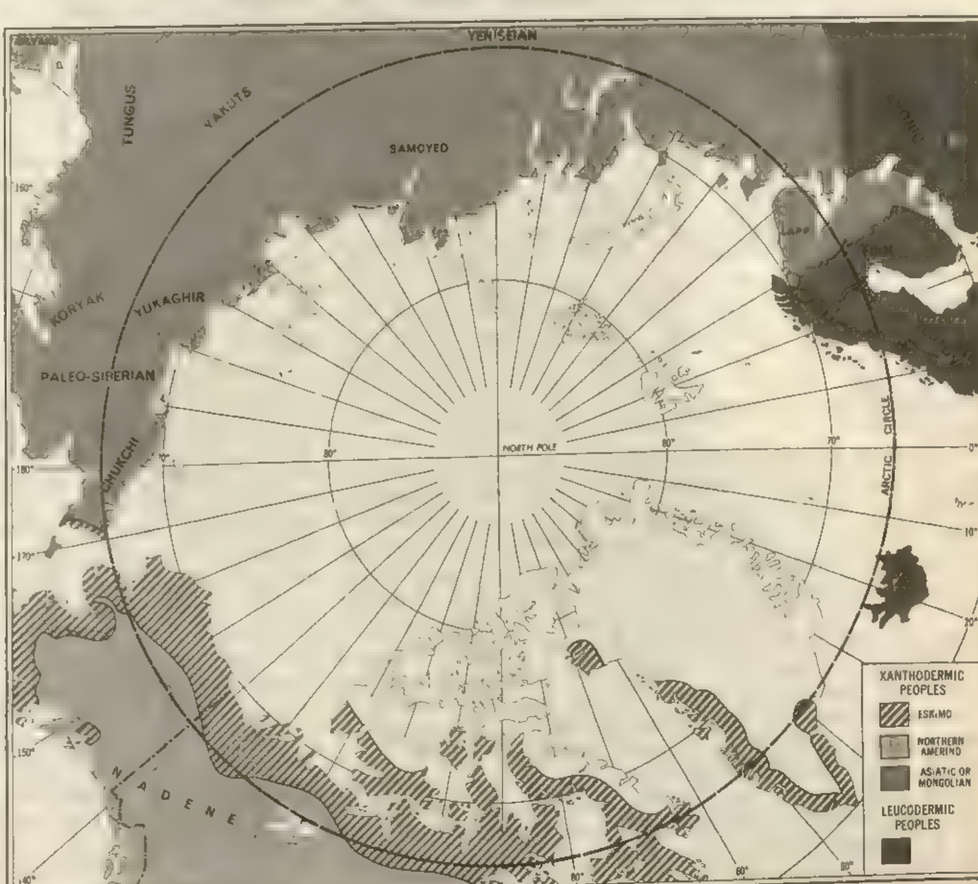

FIG. 4.—DISTRIBUTION OF NATIVE ARCTIC POPULATION

of the Altaic stock and is related to that of a number of tribes living in the Amur region: Gold (Nanai), Negidal, Orochon (Orochi), Oroki, Olchi (Ulchi).

Yakuts.—The most culturally advanced of the native Siberian peoples are the Yakuts (pop. about 236,000), who occupy the basins of the Lena river and its tributaries the Aldan and Vilyuy and farther to the north the Anabar, Olenek, Yana, Indigirka and Kolyma rivers, all within the Yakut Autonomous Soviet Socialist Republic (*q.v.*). In the south the Yakuts breed horses and cattle and practice agriculture; in the north they are mostly hunters, fishers and reindeer breeders. Their language is Turkic, one of the three divisions of the Altaic stock.

Samoyed.—The Samoyed or Nentsy (pop. about 16,000) occupy an extensive territory in northern Siberia and Europe from the Taimyr peninsula westward to the White sea. Subdivisions include the Tavgi-Samoyed (Nganasany), the Selkups and the Entsy. The Samoyed are a nomadic people who live by hunting, fishing, and reindeer herding. Their language is related to Finno-Ugrian, the two together forming the Uralic linguistic stock.

3. Arctic Europe.—Northernmost Europe and adjacent northwestern Siberia is occupied by peoples speaking either Indo-European (Russians and Scandinavians) or Finno-Ugrian. The latter substock is divided into two branches: the eastern or Ugrian, represented by the Ostyaks or Khanty and the Voguls or Mansi who live along the Ob river, and the Magyars in far distant Hungary; and the western or Finno-Permian branch, which includes the Finns, Lapps, and Zyrians. (H. B. Cs.)

IV. ECONOMIC AND SOCIAL DEVELOPMENT

The story of man in the arctic can be generalized as quests for shorter trade routes between East and West, exploitable natural resources, scientific knowledge and national security. These quests were given greater urgency by patterns of modern population concentration, population growth and human aspirations. Nine-tenths of mankind resides in the northern hemisphere, and, with the exceptions of China and India, the capitals of the major northern nations are closer to the Arctic circle than to the equator. The sea and air transportation revolutions of the 20th century have at least partly verified Vilhjalmur Stefansson's prophecy of the Arctic ocean as the new "mediterranean." Natural resources in the arctic gained greater significance by the increasing world population and the drive for better living standards.

The arctic lands are shared between Canada (approximately 37%), the Soviet Union (28%), Denmark (Greenland, 28%), the United States (Alaska, 6%), Iceland, Norway, Sweden, and Finland. Although the arctic is relatively definable physically, it cannot be delineated so easily in economic, political and social terms. Generally, the administrative and political units and the development programs merge the physical geographer's zones into more viable economic units that include southern extensions of the physically defined arctic. This review, therefore, will deal with the "far north" defined as the sum of present political and administrative units embracing the arctic proper within their boundaries.

1. Role of Location.—The spherical shape of the earth and the location and form of its main land masses provide the most dynamic factors in the development of the arctic and strongly influence that of the subarctic. Prehistoric man moved between the northern continents around the rim of the Arctic ocean, and modern man found the Pacific and Atlantic great circle routes and polar routes over the arctic the most feasible and shortest ways to travel between North America and Eurasia.

The military importance of the far north was long recognized and in part explains naval interest in polar exploration during the 19th century and the United States purchase of Alaska in 1867. During and after World War II the placement and manning of defensive and offensive facilities created new military settlements around the arctic and subarctic and required the stepping up of all manner of scientific investigations and research. The changes in the technology of warfare created continuing construction booms as widely scattered small landing fields were replaced by centralized launching facilities and detection progressed from direct human observation to ballistic missile early warning stations.

Commercial transportation and military developments created the need for a progressively expanding and elaborated system of navigational aids and scientific undertakings. Outposts for the study and forecasting of weather and sea ice conditions were essential for transpolar flights and for the safe use of the shipping lanes. As a by-product, the far north was discovered to be an ideal laboratory for research in a wide range of geophysical and biological fields.

2. Natural Resources Utilization.—Natural resources utilization took two broad forms—subsistence hunting, fishing and agriculture, and highly specialized commercial exploitation for export. Some isolated groups of people still depend upon hunting and fishing for varying degrees of their subsistence. Commercial exploitation and development for export has in general been sporadic, narrowly specialized, absentee in management and all too often ruthless and destructive. Economic factors of distance from markets and high costs determined that only resources of high contemporary scarcity value would be utilized and that the operations would be carried out with little regard for sustained yield of renewable resources and with wasteful production of only the richest deposits of nonrenewable resources. Public policy and government operation have played important roles in all northern development, ranging from the totally state-planned and -managed operations in the Soviet Union, through the state-operated trading monopoly in Greenland, to the heavy public subsidy of private development in western Europe, Canada and Alaska.

Renewable Resources.—Hard on the heels of the first explorers came whalers, and for generations the northern seas were a major source of whale oil and by-products until the resources were exhausted. Local coastal populations and larger numbers of seasonal workers of the distant-water fishing fleets of the U.S.S.R., the United States, Canada, Japan and most of the European nations engaged in the commercial harvesting and processing of marine resources organized on highly industrialized lines. These activities progressively broadened in scope from the selective exploitation of a few species and limited variety of processing to comprehensive harvesting and a greater diversity of product.

In international waters a number of treaties and arrangements attempted to minimize conflict and provide a degree of management. The Fur Seal Treaty of 1911 between Russia, Japan, the United States and Great Britain (later Canada) was unique in that it appointed Russia and the U.S. as agents to manage and harvest seal herds for the benefit of all four nations.

The great trading companies of the 16th and 17th centuries launched a stream of hunters, trappers and traders across the northern lands, opening the way for other developments and continually altering the indigenous economies. But depletion in supply and decline in quality of the fur resources, coupled with the fickleness of markets and prices, reduced the fur trade to a minor and unstable element in northern economies.

Agriculture has been dependent upon the creation of isolated local markets by military, mining and other economic developments. Soil, climate and cost factors have strictly limited crop raising and dairying. Commercial grazing of sheep has been successful on a small scale in Alaska, Greenland and Iceland, but the principal domestic animal of the far north is the reindeer, originally raised by the Lapps in the north of Scandinavia. Attempts to transplant the herding activities of the Lapps to Alaska in the last century for the benefit of the Eskimo population and more recently to northern Canada have had many reverses and are only moderately successful at a few localities, chiefly Nunivak Island in Alaska. In the Soviet Union and the Scandinavian far north reindeer husbandry is a major industry.

The boreal forests bordering the tundra zones are so extensive that the U.S.S.R. and Canada rank among the world leaders in forest resources. Except for the more accessible southern areas of these nations and the coastal forests of Alaska, however, lumbering has been limited to the meeting of local needs. Hydroelectric power potentials are impressively large, and some major developments have taken place on the southern fringes of the subarctic. Farther north, ambitious plans have been considered,

such as the Rampart Canyon project on the Yukon river and the reversing of the headwaters of the Pechora and Vichegda rivers into the Volga system.

The far north has long attracted big game hunters, sportsmen and travelers. Its still abundant wildlife, spectacular scenery and unusual wilderness constitute important assets that might lead to a significant growth in tourism.

Nonrenewable resources.—Gold has been mined in the Russian north since the 1840s and this region today is second only to South Africa in world production. The Soviet mining industry expanded into the far north following World War I and is strongly developed on the Kola peninsula, the Pechora valley and the lower Yenisei river. The U.S.S.R. also mines large amounts of copper, nickel, industrial diamonds, mica, tungsten and tin in its arctic and subarctic areas. More than half the world's nickel and large percentages of its lead, zinc, gold, silver, platinum and uranium come from the Canadian mining districts of northern Ontario, Yukon territory, Great Slave lake, Athabasca lake, northern Manitoba and the Labrador-Quebec border. Of the promising future large developments in northern Canada, the most immediate are iron ore on Ungava bay and base metals on Baffin Island and the northern mainland. Alaska's production of gold and copper slumped or disappeared before and during World War II, but there is immediate prospect of an important copper revival and long-range prospects for iron ore and other metals. Greenland produced cryolite and small quantities of lead and zinc, and northern Sweden has extensive high-grade iron ore deposits.

Conditions favourable to the formation of petroleum reserves exist in the sedimentary rock of most of the arctic and subarctic, and coal is known to exist in great quantities. The chief coal-producing areas are in the Soviet Union and the south-central and interior of Alaska, with minor production in Spitsbergen and in Greenland. Oil-producing areas include the northern Alberta fields, the Kenai peninsula-Cook inlet fields in Alaska and large areas west of the Ural mountains in the U.S.S.R. Exploration and development under U.S. government auspices have been conducted in the large naval petroleum reserves created in Alaska's arctic in 1923, and private activities are being conducted in the arctic of Alaska and Canada. Natural gas from producing fields in the far north is being piped into the industrial complex of the Urals and is also used locally in Alaska and Canada.

3. Transportation.—In economic and social terms the arctic and most of the subarctic are composed of several "islands" linked to their homelands by a few tenuous transportation lines. Within each national compartment, local systems have evolved independently in response to regional commercial and military needs. Only in the 20th century has there been serious consideration of overall transportation systems as keys to increased economic development.

The essential North American arctic sea routes are those linking Alaska to the continental United States and extending eastward to the Canadian arctic, those linking central Canada to the far north by way of Churchill on Hudson bay, and those from the Atlantic coast of Canada to the Canadian eastern arctic. Defense construction and maintenance operations caused a great upsurge in shipping after 1950, made possible by the construction of powerful new icebreakers, extensive hydrographic surveys, air reconnaissance, and large-scale mapping. For more than two centuries Denmark has had fairly regular shipping connections with west Greenland, expanding these as the economy developed and eventually maintaining them on a year-round basis. There is still a lack of good harbours on Greenland and east Greenland suffers from severe ice conditions, requiring the supplementing of far north ship transport by air carriers. On a seasonal schedule Svalbard is linked to northern Norway by ship and the Soviet Union has a similar route to Murmansk. The development of a sea route around northern Asia was a spectacular achievement of the U.S.S.R.

Within the several regional units of the far north, aviation has been the most flexible and useful mode of transportation. Civil aviation is best developed in Alaska, northern Canada and Siberia and least in Greenland and to Svalbard.

When economic development goes beyond the pioneer stage, need for surface transportation arises. In the U.S.S.R. railroads appear to be most important; new lines have been extended into the Pechora valley and to the Ob river and extensions have been made in the Murmansk area. In Alaska and northern Canada the extension of the road network is favoured. The Alaska highway with continuously expanding tributaries in Alaska and Yukon territory is a permanent part of the North American highway system. Topographic factors make it unlikely that surface land transport will ever be important in the eastern Canadian arctic and in Greenland.

4. Social and Political Characteristics.—Aboriginal populations were dispersed in kin groups, thinly spread and often on the move. Settlements were found at favourable fishing locations along the southern coasts, but it was not until the arrival of outside influences that the indigenous people lost their dominantly nomadic character and concentrated at a few places determined by trade, opportunities for employment and public services. Like the first settlers, European and American migrants and transients concentrated along coastal areas and river systems. The recent transportation and communications revolutions, however, rendered the concept of a continuous ground-contact frontier zone obsolete, and isolated islands of mid-20th-century technology and urban living can be found in the northern wilderness. Regardless of the national territory, these recent settlements present a uniform range of types: isolated technical stations (weather, ice island stations), military bases, outposts (missions, fur-trading posts), resource development settlements, regional administrative centres and multipurpose towns and cities. In the 1960s there was only one Canadian town north of latitude 60° N. with more than 1,000 inhabitants; Alaska had two with more than 10,000, while the Soviet Union had five cities with more than 100,000 inhabitants. Isolation and remoteness from population centres remained the commonplace of human life in the north.

Political development underwent frequent experimental reform during the 20th century. Although the Russians had been in the north for several centuries, only during the Soviet period was much attention paid to administration and local rule. The Russian Soviet Federated Socialist Republic stretches across the entire Asian coast of the Arctic ocean and far inland to the south. Instability of territorial patterns appear to be a permanent element in administration of the northern regions of this political unit. Administrative-territorial divisions responsible for cultural and political affairs and law enforcement have been reshuffled, with some indication of trends toward formation of more independent units across the north. Economic administration was decentralized in 1957 by creation of a network of economic administrative regions under local councils, but after 1965 there appeared to be a return to centralization.

The arbitrary boundary of the 60th parallel divides the Yukon and Northwest territories from the Canadian provinces. Within those territories the Canadian government has a dual responsibility to administer its regular federal programs as well as to perform functions of quasi-provincial administration and supervise a rudimentary legislative system. Constitutional and administrative reforms have skirted the problems of self-determination and/or self-sufficiency. However, more drastic steps toward increased self-determination were taken elsewhere. The republic of Iceland was proclaimed in 1944 after almost three centuries of Danish rule and 26 years as an associated "sovereign state." Under the 1953 Danish constitution the former colony of Greenland became an integral part of the commonwealth with representation in Parliament. A similar event occurred in 1959 when Alaska officially advanced from the limited self-rule of territorial status to become the 49th state of the U.S. (G. W. Ro.)

V. POLITICAL AND STRATEGIC ASPECTS

The arctic presents special problems with respect to ownership and control of the arctic islands lying between the mainland coasts of the surrounding continental areas and the north pole. Similarly, there are problems of jurisdiction relating to the waters between islands and the mainland, waters within the island systems themselves, the open arctic seas and that part of

the Arctic basin in a state of congelation, where pack ice and ice islands are to be found in great areas in the polar seas and comprising, of course, the polar icecap itself. Problems of jurisdiction include the question of sovereignty in the air space over the arctic and control, if any, of the waters under the pack ice.

Much of the complexity in arctic territorial claims has resulted from difficulty in applying traditional doctrines governing the acquisition of territory to these land, water, air and ice areas. Classically, international law has provided that the acquisition of territory may take place under several well-established conditions: conquest, accretion, discovery, occupation and prescription. As to the high seas, however, the doctrine of the freedom of the open sea has long been established rendering *res communes* all of the open sea except for a marginal coastal belt (the width of which varies somewhat in different countries), but even through this territorial sea ships of other nations have had rights of "innocent passage." Similarly, nations could make claims with respect to "historic bays" and, possibly, certain types of "historic waters," although in both cases the definition remains difficult. Finally, established doctrines with respect to jurisdiction in air space have provided for complete and exclusive control by a nation of the air space over its territory as well as over its territorial seas, and there are no rights of innocent passage in such territorial air space. These air law concepts, evolving from customary law through the Paris convention of 1919, were confirmed by the Chicago Convention on International Civil Aviation of 1944. Air above the open sea is as free as the open sea itself; the Geneva Convention on the High Seas (1958) reaffirmed the freedom of all states to fly there.

Because of the peculiar historical, geographic and strategic characteristics of the arctic areas, nations have not found it possible to apply these doctrines there with directness or simplicity. While discovery, apart from war, was perhaps the most important original basis for the acquisition of territory, it was replaced in the 18th and 19th centuries by the doctrine of "effective occupation." Discovery was regarded by then as providing only an inchoate or incomplete claim, to be effected by "a peaceful and continuous display of authority"; the quantum of "display" would vary, of course, with the topographical, economic and population realities in each case. Theoretically, the islands of the entire Arctic basin were open for discovery and occupation by all and ought to have been within the sovereignty of those who first discovered or effectively occupied them. However, there emerged very early in the developing boundary treaties of countries bordering the Arctic basin, specifically between Russia and the United Kingdom in their conventions of 1824 and 1825, the notion that the line of demarcation between British North America and Russian-American territory extended beyond their arctic coasts and ran ". . . in its prolongation as far as the Frozen Ocean . . . ." This language was repeated, with some modification, in the treaty between the United States and Russia in 1867 when Alaska was purchased by the United States.

This concept of sovereignty or jurisdiction extending northward beyond the mainland within longitudinal lines has become known as the "sector theory"; upon it both Canada and the U.S.S.R. appear to base their present claims to sovereignty over all lands within their triangular sectors up to the pole, whether discovered, effectively occupied or not. The nations most directly concerned with the sector theory are not only those that benefit from a long arctic coast line, such as Canada and the U.S.S.R., but also others such as Denmark in the case of Greenland and the United States in the case of Alaska. Presumably smaller sectors also are available to Iceland and Norway.

Most countries interested in the arctic seem to have accepted the sector principle with respect to land (that is, the arctic islands and territorial waters surrounding them), although the United States has at times maintained a noncommittal attitude. Consequently, it is unlikely that nations having sector claims would accept claims of any other state based on discovery or occupation; and conversely, nations making such discoveries are not likely to assert claims to lands or islands found in sectors of other states.

What remains very much in doubt, however, are the claims put forward by a number of Soviet scholars—with some apparent support from the government of the U.S.S.R.—over (1) the open waters between islands or between islands and the mainland; (2) that part of the Arctic ocean where no islands are to be found; (3) arctic ice islands and the ice pack; (4) the air space above the entire sector. Most nations and scholars would deny such broad claims by sector states. The problem may have been complicated, however, by the decision of the International Court of Justice in the Norwegian Fisheries case (1951), in which it was held that the great archipelago off the Norwegian coast could be treated as a geological formation integrated with the mainland and that, therefore, the waters of the fjords, extending in some cases 40 mi. from the mainland out to sea, should be regarded as national or internal waters, with territorial waters a further 4 mi. beyond a base line drawn from the outer rocks and shoals of the island system. While the decision may not be applicable to all the arctic islands, the reasoning does suggest, particularly in the case of Canada, the possibility of claims based on a "zone of attraction" or on the geological connection between the great Canadian arctic islands and the Canadian mainland.

With respect to the open seas of the arctic, such as Beaufort sea north of North America and the Barents and Laptev seas north of the U.S.S.R., claims of jurisdiction are not regarded as well founded either as to the waters themselves or the air space above them. Equally, there would seem to be no serious international acceptance of claims to sovereignty over the arctic ice islands or the icecap. The polar cap comprises pack ice at an average depth of 8 to 12 ft. with substantial areas now known to be open. While it does not have the solidity so often assumed for it previously, large areas are nevertheless sufficiently firm to be available for temporary use by meteorologists as well as for air navigation, general scientific work and presumably military purposes as well. The ice is in constant motion, moving in a counterclockwise direction around the pole, thus making it quite possible for Russian, U.S. or Canadian bases to move into each other's sector over a period of time if these were set up on the ice

Finally, the doubtful basis for any claims of jurisdiction over the pack ice within their respective sectors makes it impossible for any of the sector states to claim jurisdiction over the waters under the pack ice. The Russian claims there seem more determined than the Canadian, although some distinction is being drawn in Canadian government statements between the open Arctic ocean and the polar icecap.

Another modern development which may have commercial significance in the future is that of the "continental shelf" doctrine, given international recognition by the Geneva convention of 1958. The convention made it clear that states will be able to assert jurisdiction over a shelf of land covered by not more than 200 m of water for as far northward from the arctic mainland as that shelf may extend at such depth, and for even larger areas if the shelf can be exploited for its natural resources at a greater depth. The convention further provided, however, that exploitation of the shelf for its resources must not interfere with the legal status of the high seas or air space beyond territorial waters.

It may be concluded, therefore, that while the sector theory in the arctic has not been formally adopted by states other than those benefitting substantially from it, such as Canada and the U.S.S.R., it seems quite firmly established with respect to lands and their territorial waters but not to open waters, air space, ice islands and pack ice. It would not seem possible to apply to the Arctic procedures similar to those provided for by the Antarctic treaty. (MA. C.)

VI. FUTURE DEVELOPMENT

Vilhjalmur Stefansson lived to see his thesis "northward the course of empire" being verified. Great aircraft on international flights now range daily far over the Arctic ocean, while nuclear submarines can cruise almost at will beneath its shifting ice cover, Alaska has become a state of the U.S., Soviet icebreakers annually lead ships in substantial numbers along Siberia's northern coast between the western U.S.S.R. and the Pacific, and mining and petroleum exploration and development penetrate farther and

farther north in both the eastern and the western hemispheres.

Trevor Lloyd of McGill University has pointed out, "In spite of the map on the schoolroom wall the Arctic Ocean is not a strip of ice-filled water along the upper edge of the world, but a comparatively small, almost enclosed sea, in reality a gulf of the North Atlantic. From its shores the world's land masses radiate toward the south. It is in a literal sense a 'mediterranean' lying in the middle of the continents."

Of great importance in the opening of the Arctic is the situation also pointed out by the same authority that "Although the land areas surrounding the polar basins have a natural unity, their present-day political and socioeconomic diversity has been brought about by influences from farther south. These have extended northward from the mid-latitude lands, occupied by peoples of varying history and culture, creating striking circumpolar differences where uniformity or at least similarity might have been expected. The Eskimos, once a unified culture from west of Bering Strait to East Greenland, confront the world today as citizens of the United States, Canada, Denmark, or the Soviet Union and with only the most tenuous of links remaining between them."

Only a modest beginning has been made in the detailed geological mapping of the north polar lands, yet they have long been important sources of a number of minerals which have a great potential for further exploitation. In the Soviet Union development and exploitation of mineral resources have gone on apace—the great northward-flowing rivers like the Ob and the Yenisei have provided links between the Trans-Siberian railway to the south and the northern sea route. Settlements like Norilsk and Yakutsk have become cities and are gaining importance nationally. The Canadian north is stirring too; large iron deposits have been found and are being appraised in the east on Baffin Island and in the west in the Yukon Territory. Other minerals also are being exploited. It is reported, for example, that the total leaseholdings for petroleum exploration in the Yukon Territory and Northwest Territories of Canada now approach 160,000,000 ac. The ultimate reserves in those territories are estimated at nearly 50,000,000,000 bbl.

Alaska, too, is sharing in the surge of northern interest, exploration and development. Though it is true that not all of Alaska is properly considered arctic, the progress of the new state is indicative of northern gains in general. By the mid-1960s production in both the fisheries and mining industries had reached record levels.

Perhaps the least touched of all arctic resources are those that can be designated as recreational. Fishing and hunting are expanding as transportation and communication become cheaper and more widely available. In many parts of the Arctic, scenery is a valuable asset and is being exploited at an increasing rate. Cruises in the fjord regions of Norway have long been famous, and in time some of the similar fjords of Greenland may become well known to tourists. (J. C. R.)

Current developments are summarized annually in *Britannica Book of the Year.*

ARCTINUS (fl. 776 B.C.), of Miletus, one of the *Homeridae* ("Descendants of Homer") and traditionally the author of two poems in the lost Greek epic cycle. Proclus says in his *Chrestomathia grammatica* that Arctinus wrote the *Aithiopis* ("Ethiopian"), a sequel to the *Iliad* narrating the deeds and death of the Amazon Penthesilea, of Memnon the Ethiopian king and of Achilles, and the *Iliou Persis* ("Sack of Troy"). Both are assigned to other authors by other ancient sources, one of which attributes the *Titanomachia* ("Battle of the Titans") to Arctinus.

BIBLIOGRAPHY.—Fragments in T. W. Allen's ed. of Homer in the Oxford classical texts, vol. 5 (1912), and in H. G. Evelyn-White's ed. of *Hesiod* with Eng. trans. in the Loeb ed. (1926). *See* also T. W. Allen, *Homer: the Origins and the Transmission*, ch. 3, pp. 51–77 (1924).

ARCTURUS, one of the brightest stars in the northern hemisphere, situated in the constellation Boötes (*q.v.*) in an almost direct line with the tail of the constellation Ursa Major ("Great Bear"); hence its derivation from the Greek words for "bear guard." It is an orange-coloured giant star at a distance of about 40 light years from the sun. For the Greek myth of the origin of the star, *see* CALLISTO.

ARCULF, a Frankish bishop and pilgrim-traveler, who visited the Levant about 680, and was the earliest Western Christian traveler and observer of any importance in the Near East after the rise of Islam. On his return he was driven by contrary winds to Britain, and so arrived at Iona, where he related his experiences to his host Adamnan, abbot of Iona. The narrative of his journey, *De locis sanctis*, as written by Adamnan (*see* ADAMNAN, SAINT), came to the knowledge of Bede, who inserted a brief summary of it in his *Ecclesiastical History of the English Nation*, and also drew up a separate and longer digest that obtained great popularity throughout the Middle Ages as a standard guidebook to the holy places of Syria.

The *De locis sanctis* was edited and translated by D. Meehan (1959).

ARDABIL (ARDEBIL), the chief town of a district in Eastern Azerbaijan, or Third *ostan* (province) of Iran, lies about 105 mi. E. of Tabriz and 38 mi. from the Caspian sea. The population (1964 est.) of 87,196 is Turkish-speaking. It stands on an open plain at the eastern foot of Mt. Sabalan (15,784 ft.), at 4,500 ft. above sea level. The climate is one of extremes, cold spells occurring until late in the spring. Delicate fruit trees are therefore excluded, but cereals, pulses and melons are abundant. The town once served as an entrepôt for the exports of inner Azerbaijan through

the Caspian port of Astara to Russia but has stagnated since this port ceased to function. There is no significant industry except for carpets and rugs. Warm mineral springs found nearby are much frequented.

Ardabil was the capital of Azerbaijan after the Arab conquest but later lost this distinction to Tabriz. It was heavily sacked by the Mongols but rebuilt. In the 14th century it was the residence of Sheik Safi al-Din who died there; his shrine is an object of general veneration and is frequently visited by Iranians. The sanctuary also contains the tombs of several of his descendants including that of Shah Ismail (d. 1524), the founder of the Safawid dynasty. The European travelers Olearius (1637) and Chardin (1671) describe Ardabil as one of the most flourishing Persian towns of their time. The sanctuary suffered considerably in the sack of the town by the Russians in 1827, and the famous library of Sheik Safi, once the greatest in all Persia, was sent to St. Petersburg to become part of the imperial library. (H. Bo.)

ARDASHIR, the later Persian form of the royal name Artakhshathra (*see* ARTAXERXES), borne by the founder of the Sasanian dynasty of Iran and by two of his descendants.

ARDASHIR I reigned over Iran from *c.* A.D. 224 to *c.* 240. At the turn of the 2nd century the chief petty king in Persis was Gochihr, of the Bazrangi family, ruling at Istakhr. Among his vassals was Papak, son or descendant of Sasan and connected through his mother with the Bazrangi. He had charge of the temple of Anahita in Istakhr and obtained for Ardashir, one of his younger sons, the military post of *argabad* in the town of Darabgird. From there Ardashir extended his control over several neighbouring cities, killing their regent princes. His father meantime slew Gochihr and took the title of king. He sought leave from the Parthian king of kings, Artabanus V, to transmit the crown to his eldest son Shapur, but Artabanus refused, addressing him as a rebel. When Papak died soon after, Shapur nevertheless succeeded him. A struggle ensued between him and Ardashir, in which Shapur died. Ardashir was crowned king of Persis in A.D. 208, after which he put to death a number of his other brothers. Having suppressed a revolt in Darabgird, he gradually conquered the neighbouring province of Kerman (over which he set one of his sons, also called Ardashir) and the coast lands of the Persian gulf. He made his capital at Gur (modern Firuzabad), which he renamed Ardashir-Khurre.

Ardashir then moved against the west. He first took Isfahan; then conquered Ahvaz (Susiana), the ruler of which had been ordered by Artabanus to attack him, and Mesene. From there he withdrew again to Persis, before encountering in 224 the Parthian army at Hormizdagan (site unknown), where he won a decisive victory, slaying Artabanus. (According to one classical source, Ardashir defeated the Parthians three times; but this may only reflect these three western campaigns.) Soon after, Ardashir entered Ctesiphon in triumph and, as master of Babylon, was crowned with the imperial title "king of kings." The date of this coronation is generally held to be 226, but it is argued that it may have been 224, directly after the great victory. (For Ardashir's further conquests *see* PERSIAN HISTORY.)

With his son and successor, Shapur I, Ardashir established the Sasanian empire. Nothing is known of him except his deeds, which show him ruthless, a great soldier, and a strong and able king. He founded or rebuilt many cities, of which the following have been identified: Veh-Ardashir (ancient Seleucia) and Weh-Ardashir (Goasir in Kerman); Astrabad-Ardashir (ancient Karkha of Mesene); Hormizd-Ardashir (Ahwaz); Wahishtabad-Ardashir (later refounded as Basra); Rew-Ardashir (Rishahr by Arrajan); Ardashir-Khurre (Firuzabad); Bokht-Ardashir (possibly Bushire). He is also credited with digging canals and building bridges. Several great rock carvings commemorate his reign. Two investiture scenes, at Naqsh-i Rajab and Naqsh-i Rustam near Istakhr, show him receiving the kingly diadem from the god Ahura Mazda. The latter carving has a brief trilingual inscription, in Middle Persian, Parthian and Greek; in the Greek version the king's name appears as Artaxerxes. In this relief he is shown mounted, with a dead Parthian lying beneath his horse's hooves. Scenes from his victory over Artabanus are carved in a gorge near Gur and a third investiture scene exists there. The ruins of Ardashir's palace and castle also survive.

Ardashir made Zoroastrianism the state religion, and he and his priest Tosar are credited with collecting the holy texts and establishing a unified doctrine. Two 6th-century treatises, *The Testament of Ardashir* and *The Letter of Tosar*, are attributed to them for greater authority. They survive in Arabic and Persian versions. As patron of the church, Ardashir appears in Zoroastrian tradition as a sage. As founder of the dynasty, he is celebrated in a 5th-century Pahlavi book, the *Karnamag-i Ardashir*. This is largely a romance, which may embody in part old Persian oral traditions concerning Cyrus the Great, transferred to Ardashir. In it and in some versions of the official chronicles, Ardashir's ancestry is traced back to the Achaemenidae and Kayanians (patrons of Zoroaster).

ARDASHIR II reigned from 379 to 383. Under his brother Shapur II he had been king of Adiabene, where he took part in the persecution of the Christians. After Shapur's death he was set on the throne of Iran by the nobles, presumably at an advanced age. His investiture is commemorated in a rock carving at Taq-i Bostan. He tried to assert himself but was deposed after four years.

ARDASHIR III reigned from 628 to 629. The son of Kavadh II, he was made king of Iran when seven years old, under the regency of Mah-Adur-Gushnasp, but was killed by his general Shahrbaraz 18 months later. (MA. B.)

ARDEA, a village in the modern Italian *regione* of Lazio, 3 mi. from the coast and 23 mi. S. of Rome by the Via Ardeatina. An ancient town of the Rutuli, it is mentioned frequently by Virgil, who associates it with Danae and Juno (of whose cult it was an important centre). It was an early Iron Age settlement (early 8th century) which developed into one of the most important Latin cities, a member of the Latin leagues of the 6th and 5th centuries B.C. In 444 it signed a treaty with the Romans who, according to Livy, colonized it as a barrier against the Volsci. The decline of Ardea, from the 4th century onward, was hastened by malaria and the wars under Marius and Sulla in the 1st century B.C. Under Augustus only traces of the city survived, but villas and possibly a Hadrianic colony kept the village alive; nearby a herd of imperial elephants was maintained.

The early citadel lay at the end of a plateau between two valleys, with tufa cliffs about 60 ft. high; it was defended on the east by a fine tufa wall. The settlement spread farther south and east and was defended from 400 B.C. or earlier by mounds and ditches, of which impressive remains survive. There are also traces of two temples (from the 6th century) and a basilica (1st century B.C.). Ruins on the coast may be those of the ancient harbour Castrum Invi.

See B. Tilly, *Vergil's Latium* (1947); A. Andren, *Opuscula Romana*, vol. i (1954) and iii (1961). (H. H. SD.)

ARDÈCHE, a *département* of southern France astride the Cévennes edge of the Massif Central, is bounded on the east by the Rhône river, to the south by Gard, to the southwest by Lozère, and to the northwest by Haute-Loire and Loire *départements*. Area 2,145 sq.mi. Pop. (1962) 248,516, considerably less than at the end of the 19th century. The chief town is Privas. The *département* was formed in 1790 from the Vivarais district of Languedoc (*q.v.*). There is generally little lowland on the right bank of the Rhône and most of Ardèche is highland, built of ancient crystalline rocks and vigorously dissected by right-bank tributaries of the Rhône, which have torrential régimes and flow in deep, steep-sided valleys. The chief of these is the Ardèche river, which gives its name to the *département*. North of its valley the volcanic hills of the Coirons jut out southeast toward the Rhône valley, and on the western border of the *département* Mt. Mézenc (5,755 ft.) is part of the volcanic plateau of Velay. The upper Allier river forms part of the western boundary with Lozère.

In sheltered valleys near the Rhône the climate is warm, but on the higher ground winters are long and severe. Cereals, potatoes, and especially fodder crops are cultivated, the meadows often being irrigated to produce a succession of hay-cuttings during the sum-

mer. Fruit trees, vines, and even olives are grown in the lower parts of the valleys, and at a higher level, up to about 2,500 ft., the sweet chestnut is an important crop, although it is no longer an important staple of the peasant diet. Mulberry cultivation (for silkworms), for which the hillsides were extensively terraced, has greatly declined. Above the limit of cultivation are upland pastures that provide summer grazing for sheep and goats, but the highlands have been largely denuded of former woodlands. Although sericulture is no longer important, several textile mills remain active, now using hydroelectric power. There are also glove and paper industries. Ore deposits have been worked at several places on a small scale, and medicinal springs are numerous, the chief being Vals-les-Bains, Saint-Laurent-les-Bains, Celles, and Neyrac.

The main road from Le Puy to the Rhône valley at Montélimar traverses the *département* by the Ardèche valley through Aubenas. The towns of Privas (the capital), Largentière, and Tournon give their names to the three *arrondissements*. The *département* forms the diocese of Viviers in the archbishopric of Avignon; it is in the educational area of Grenoble, and under the court of appeal at Nîmes. Privas was extensively destroyed in the religious wars of the 17th century, but there are many interesting Romanesque churches elsewhere, as at Bourg-Saint-Andéol and Thines, and the cathedral at Viviers has a fine rock site that dominates the town. (Ar. E. S.)

ARDEE (Baile Átha Fhirdiath), a town in County Louth, Republic of Ireland, lies on the river Dee, 42 mi. N.N.W. of Dublin by road. Pop. (1961) 2,710. The town is of great antiquity and its Gaelic name means "the town of the ford of Ferdia," who, according to legend, was slain here by Cú Chulainn. To the southeast is a large rath, or encampment, with remains of fortifications. Roger de Pippard, lord of the manor early in the 13th century, is said to have founded the church (the present Protestant church) and to have built Ardee castle, now used as a courthouse. The adjacent Hatch's castle is also medieval. Ardee received its first recorded charter in 1377. It was sacked by Edward Bruce in 1315 and by Conn O'Neill in 1538, taken by the Irish and recaptured by the English in the wars of 1641, and occupied later by the forces of James II and of William III. Besides being a market and shopping centre, Ardee manufactures textiles and furniture.

ARDEN, FOREST OF, a district in the western part of Warwickshire, Eng., originally part of a huge forest tract that covered the county from the Avon river north to the present site of Birmingham and stretched westward far beyond the present county boundary. The name is still preserved in Henley-in-Arden and Hampton-in-Arden. Wide lands in the district were held in Edward the Confessor's day by Alwin (Aelfuine) whose son, Turchil of Warwick, or of Arden, founded the family of the Warwickshire Ardens who still held several of the manors in the time of Queen Elizabeth I; Mary Arden, Shakespeare's mother, claimed to be of this family. Shakespeare knew the district well and was probably inspired by it when he depicted forest life in *As You Like It*. Though not a royal forest, it was subject to forest laws at the time of the Domesday survey but now no trace of the original forest of Arden remains.

ARDENNES, a district covering some portion of the ancient forest of Ardenne, extends over the greater part of the Belgian province of Luxembourg, part of the grand duchy and the French *département* of Ardennes. One derivation of the name is from a word meaning "the forest," turned into Latin as Arduenna Silva and derived from the Celtic word *ardu* ("dark," "obscure"). Another derivation is from *ar-Denn* or *ar-Tann*, Breton for "the, or among the, oaks," whence Ardenne would be a forest of oaks. A. Carnoy derives it from a Celtic form for high-land, *Ardu-enna* being from the Indo-European *arduos* ("high"). The Arduenna Silva was the most extensive forest of Gaul, and Caesar's *Commentarii de bello Gallico* describes it as extending from the Rhine and the confines of the Treviri to the limits of the Nervii. At the division of the empire of Charlemagne between the three sons of Louis the Débonnaire, under the pact of Verdun in 843, the Ardenne forest became the district pagus Arduensis. It was part of Lothair's share, and charters of 843 specify certain towns as in this pagus. In the 10th century the district had become a comitatus, subject to the powerful count of Verdun, who changed his style to that of count of Ardenne.

The geographical region of the Ardennes comprises the western part of a group of uplands lying across the basin of the Rhine. They consist of Lower Paleozoic rocks, mainly Devonian sandstones and quartzites, with some outcropping masses of Cambrian and Silurian slates (notably in the Stavelot massif in the northeast), and limestones in the north near Dinant. The Ardennes owe their structural features to the Hercynian orogeny of late Carboniferous-Permian times, producing a series of major upfolds and downfolds trending broadly from northeast to southwest. Since this folding, alternations of prolonged denudation with uplift and tilting have produced an upland area standing prominently above the surrounding lowlands. Several continuous surfaces can be distinguished at 1,800, 1,500 and 1,300 ft. The higher parts form rounded summits (the highest, the Botrange, attains 2,277 ft.). Rivers flow rapidly outward over the impermeable rocks, becoming incised within narrow and sinuous valleys. The high Ardennes form a major watershed between streams flowing west and north to the Meuse, which is trenched across the uplands from south to north, and those flowing east and south to the Moselle. In the limestone areas of the Famenne is considerable underground drainage, notably in the case of the Lesse (*q.v.*) near Han.

The plateau surface consists of gentle heath-covered eminences, separated by shallow depressions, often containing peat bogs, or wet moorlands, notably the Hautes Fagnes (Hohe Venn) in the northeast. Woodland covers about one-half the total area, occurring both in the deeply cut valleys, with mainly oak-birch and beech forests, and also on the plateau, with plantations of spruce and Scots pine. The forest is best developed in Belgium, because of the compulsory law of replanting, but coniferous plantations were extended in Luxembourg, especially after 1945. There is an immense quantity of game, including red and roe deer and wild boar; shooting is strictly preserved.

The thin acid soils developed on the siliceous rocks are for the most part infertile, and waterlogging is common, for precipitation is heavy (Chiny, with a 49.6 in. mean, is the wettest place in Belgium). Some of this precipitation is in the form of snow, which lies for about 30 days each year at heights of more than 1,000 ft. Low clouds, hill fogs and frequent frosts make the Ardennes distinctly bleak. Most of the small extent of farmland is under permanent grass; beef cattle are bred to be sent to the lowlands for fattening, and there is dairying in sheltered valleys. Arable farming, mainly the cultivation of oats, rye, trefoil and potatoes, is carried on in the valleys and basins, and tobacco is grown in the sheltered valley of the Semois, a tributary of the Meuse.

The density of population is well below 100 per square mile, and much of the area is unpopulated. A few small market towns stand on the plateau, mainly along the railway lines: Butgenbach, Bullange, St. Vith, Bovigny, Libramont and Bastogne. The chief town in the French Ardennes is Charleville-Mézières (*q.v.*), and in Luxembourg is Wiltz, in the river valley of the same name. Industry is limited to quarrying, particularly of quartzite for road metal, timber cutting, leather tanning at such towns as Malmédy and Stavelot (*q.v.*), and woolen manufacturing at small towns in the northeast. Some towns are tourist centres, utilizing the wooded valleys and attractive walking country; the most famous resort is Spa (*q.v.*), once called "the café of Europe," with its mineral springs.

In World War I, the Ardennes became a battleground, the scene of bitter fighting (1914 and 1918). During World War II several of the towns were partly or wholly destroyed during the German Ardennes offensive of Dec. 1944, but have been rebuilt. (F. J. M.)

ARDENNES, a *département* of northeastern France bounded by Belgium, comprises the southwestern margin of the Ardennes highland and the adjacent lowlands in the valleys of the Meuse and Aisne rivers, which are connected by the Ardennes canal. Area 2,028 sq.mi. Pop. (1962) 300,247. After traversing Lorraine in a south-north valley cut in a limestone plateau, the Meuse turns

northwest as it approaches the Ardennes. Its course was superimposed upon this mass of hard, ancient rocks from a cover of younger sediments that were stripped away, and from Mézières to the frontier town of Givet the river flows in deeply entrenched meanders, some of which provide defensive sites for castles and towns, such as Mézières and Revin. Slate quarrying is carried on along the valley, notably at Fumay. In the southeast of the *département* is the northern part of the rugged massif of the Argonne, drained by the Aisne river, which emerges toward Rethel into a fertile valley in the chalklands of northern Champagne. The Aisne valley and the flanking chalk country of the western, low-lying part of the *département* are well cultivated, but the Argonne and Ardennes are extensively forested. Elsewhere the Ardennes uplands, with poor soils and an inclement climate, are used for sheep pasture. Sedan (*q.v.*) on the Meuse and Rethel on the Aisne have old-established woolen manufactures. Charleville-Mézières, besides being an important railway junction, has iron industries.

Mézières is the capital of the *département*, which is divided into the *arrondissements* of Mézières, Rethel and Vouziers. It lies in the archbishopric and in the educational province of Rheims, but for judicial purposes is served by the appeal court at Nancy. (Ar. E. S.)

History.—In spite of the unsuitability of the terrain for the rapid movement of troops the area was the scene of several important battles: the campaign of 1794 in the French Revolutionary Wars (*q.v.*); the Franco-German War (*q.v.*), with the surrender of Napoleon III at Sedan in 1870; the battle of the Ardennes in World War I and the bitter fighting between the Germans and the Americans in the Argonne in 1918 (this was the first area in which large U.S. forces were committed); and, in World War II, the German breakthrough near Sedan in May 1940 which marked the battle of France and the short-lived penetration in the Ardennes of the Germans (their last offensive action) in Dec. 1944.

ARDMORE, a city of south central Oklahoma, U.S., about 100 mi. S.E. of Oklahoma City; seat of Carter county. (For comparative population figures *see* table in Oklahoma: *Population.*) Founded in 1887 following the arrival of the Santa Fe railroad, the town was named for the Philadelphia suburb that was the home of one of the line's officials. It was incorporated in 1898 and the commission-manager form of government became effective in 1921. It developed as the business centre of a large cattle and farming region. After the discovery of oil nearby in 1905, the city grew rapidly. During the 1930s Ardmore became a tourist and recreational centre.

The city has an oil refinery, processing and fabricating plants for other raw materials and factories that produce leather goods, clothing and wood products.

Ardmore is the site of a medical and agricultural research centre, Carter Seminary for Indian children and a war veterans' home. Lake Murray state park and the Arbuckle mountains are nearby vacation areas. Ardmore maintains an industrial aviation centre 16 mi. to the northeast. (J. D. Mo.)

ARDROSSAN, a seaport and small burgh in Ayrshire, Scot., lies on the Firth of Clyde 29 mi. S.W. of Glasgow by road. Pop. (1960) 9,573. The town is under a provost and council. It has a ruined castle with a dungeon known as Wallace's Larder. Both town and harbour were created in 1806 by Hugh Montgomerie, 12th earl of Eglinton, but the intended canal connection with Glasgow never materialized, as there is an excellent rail service between the two places. During summer months there are also regular steamer services to Arran, the Isle of Man and Belfast. The 17-ac. harbour accommodates vessels of up to 12,000 tons. Shipbuilding and repairs are among Ardrossan's main industries. It has an oil refinery and imports metal products, naphthalene, fertilizers, oil and gasoline. Coal and iron are exported. (W. R. W.)

AREA RULE. Bodies which pass through the so-called transonic zone, the zone separating speeds below from those above the speed of sound, suffer a great increase of drag coefficient as they approach the critical speed. During World War II the German aircraft designer D. Kuchemann advanced the theory that drag could be reduced by remolding such bodies (for example, fuselages) to follow the local streamlines. After the war, designers tackled these problems and, in April 1952, working in the transonic wind tunnel of the U.S. National Advisory Committee for Aeronautics, Richard T. Whitcomb was able to express his "area rule" thus: "If a wing/body combination (including external paraphernalia) be so designed that the axial distribution of cross-sectional area normal to the airflow is the same as that of a minimum-drag body, the design will have minimum drag." In applying the area rule, additions to cross-sectional area (such as engine nacelles) are compensated for by subtractions from it elsewhere (*e.g.*, by narrowing parts of the fuselage). *See* Aerodynamics; Mechanics, Fluid. (D. Cr.)

ARECIBO, a municipal district on the north coast of Puerto Rico, about 50 mi. W. of San Juan, the capital of the island. Its population in 1960 (urban and rural combined) was 69,879, a sharp drop from 75,361 in 1950. The city proper had a population of 28,659 in 1950 and 28,828 in 1960. Arecibo serves as a commercial and industrial centre for a varied agricultural district and is the largest, in area, and one of the oldest municipalities of the island. It is located at the mouth of the Río Grande de Arecibo, one of the more important island rivers and is connected by highways and railroads to the other cities of the island.

The municipality was authorized as early as 1537 by the Spanish crown. The town itself was founded in 1616 by Felipe de Beaumont, the Spanish governor, who gave it the name of San Felipe Apóstol del Arecivo. The fertile plains to the east and south are rich in sugar and pineapple. Farther into the interior coffee is grown, and to the south and west small farms produce cotton, fruits and vegetables. At least 12 small industries have been established in the town with government help. A small but little-used landing strip is available for commercial and private planes. (T. G. Ms.)

ARENARIA or Sandwort, a genus of plants of the pink family with small white flowers. They are annual or perennial, mostly weedy herbs and the majority inhabit sandy soil in temperate, arctic or alpine regions. There are about 160 species; some are cultivated for ornament.

ARENBERG (Aremberg), the name of a European princely family that formerly held extensive lands in what is now Belgium and in northwestern Germany. It took its name from that of Arenberg, a hamlet about 27 mi. S.S.W. of Bonn in Germany, which came into the possession of the house of La Marck (Mark) through the marriage, in 1299, of Engelbert II of La Marck and Matilda, heiress of its former lords. Passing to Engelbert's third son Everard (Eberhard), the title of lord of Arenberg remained with the latter's descendants till 1547, when Jean de Ligne, baron de Barbançon (d. 1568) assumed it by virtue of his marriage with the sister of Robert III of La Marck-Arenberg. Raised to a countship of the Holy Roman empire in 1549, the Arenberg lands were in 1576 made a principality of the empire for Jean's son Charles (d. 1616). Charles, moreover, greatly increased the family possessions by his marriage to Anne de Croy-Chimay, which brought the duchy of Aerschot to the house. His grandson Philip Francis was granted the title of duke of Arenberg by the emperor Ferdinand III in 1664.

In the course of the Napoleonic reorganization of western Europe the 6th duke, Louis Engelbert (d. 1820), lost his lands west of the Rhine in 1803, but was given Meppen and Recklinghausen and recognized as a sovereign duke in compensation. He abdicated, however, in the same year and was succeeded by his son Prosper Louis (d. 1861). Deprived of his duchy in 1810, Prosper Louis recovered it at the Congress of Vienna in 1815 but was mediatized (*see* Mediatization), Meppen being made subject to Hanover and Recklinghausen to Prussia.

See E. Laloire, *Généalogie de la maison princière et ducale d'Arenberg (1547–1940)* (1940).

ARENSKI, ANTON STEPANOVICH (1861–1906), Russian composer of instrumental music, operas and songs, was born at Novgorod on Aug. 11 (new style; July 30, old style), 1861. He studied composition with Rimski-Korsakov at the St. Petersburg conservatory and from 1882 to 1895 taught harmony, and later

composition, at the Moscow conservatory. He was also active as a conductor in Moscow. From 1895 to 1901 he was director of the imperial chapel in St Petersburg. The last years of his life —shortened by dissipation and ill-health—were devoted to composition. He died at Terijoki, Finland, Feb. 25 (N.S., 12, O.S.), 1906. Although a pupil of Rimski-Korsakov, Arenski was more akin to Tchaikovsky; the predominant moods of his not very individual music are lyrical and elegiac. He excelled in the solo song. Of his three operas only the first, *A Dream on the Volga* (after a play by A. N Ostrovski; Moscow, 1892), was successful; the one-act *Raphael* (Moscow, 1894) was stillborn and *Nal and Damayanti* (composed 1899; performed Moscow, 1904) failed to keep the stage. Other stage-music includes music to Pushkin's *Fountain of Bakhchisarai* and Shakespeare's *Tempest*, and a ballet, *Egyptian Night*. Arenski's orchestral music, which includes two symphonies, a violin concerto and a very early piano concerto, is seldom heard. He was more at home in chamber music, and his Piano Quintet in D major, his well-known Trio in D minor and his two string quartets (of which the second, in A minor, contains the fine variations on Tchaikovsky's *Christ in His Garden*, also arranged for string orchestra) show him at his best. (G. Ab.)

AREOPAGUS, a low hill northwest of the acropolis in ancient Athens, noted as the meeting place of the city's earliest, aristocratic council, the name being extended to denote the council itself. This council probably went back to the regal period. When monarchy gave way to aristocracy (at some date between *c.* 1000 B.C. and 682/681 B.C., when the list of archons begins), membership was for life and was secured by having served as archon (*q.v.*). Archons were elected either by the people or more probably by the Areopagus itself. Only nobles (*eupatridai*) were eligible. The Areopagus exercised a general religious authority and expounded the law. In the absence of a written code this latter function gave it great power, which must have been curtailed by Draco's publication of the law *c.* 621 B.C. Solon (*q.v.*), archon 594 B.C., materially altered its composition and authority. He deprived the *eupatridai* of their monopoly of membership by opening the archonship to all with a certain property qualification. Election was to be, on one view, directly by the people, on another by sortition from 40 candidates elected by them. Solon allowed appeal in certain unspecified cases from magistrates' judgments to the court of the people (*heliaia*), which must have weakened indirectly the authority of the Areopagus as expounder of the law. Finally he may have set up a rival council of 400 (*see* BOULE). Nevertheless the Areopagus retained "guardianship of the laws" (perhaps a kind of legislative veto); it tried prosecutions under the law of *eisangelia* (impeachment) for unconstitutional acts and homicide cases. Since the tyrants who ruled Athens from 561 to 510 B.C. secured the archonships for their own adherents, on their fall the Areopagus must have been full of their nominees, and its prestige therefore at a low ebb. Cleisthenes (*q.v.*) in 508 B.C. made no direct attack on it. But he set up a council of 500 and it is probable that impeachment could proceed by way of this council and the assembly (ecclesia). On the other hand, from that time until 487 B.C. archons were directly elected by the people, so that by 480 B.C. the Areopagus was made up of prominent politicians and its patriotic posture during the Persian invasion restored its prestige. Thus, with its dormant rights of legislative veto and impeachment, it could form the rallying point of resistance to democratic advance. Hence in 462/461 B.C.—although the personal prestige of the Areopagites was again declining as a result of the fact that from the archonship of 487/486 B.C. archons were chosen by lot from 500 elected candidates and had lost much of their importance—the radicals Ephialtes and Pericles (*q.v.*) deprived the Areopagus of virtually all its powers save jurisdiction on homicide. In 458/457 B.C. the property qualification for archons was lowered and later every citizen was deemed to be qualified. Nevertheless the Areopagus retained something of its esteem so that in the political struggles at the end of the 5th century B.C. both oligarchs and democrats contemplated a restoration of some of its powers. From the middle of the 4th century B.C. its importance began to revive, and by the period of Roman domination in Greece it was again discharging significant functions, administrative, religious and educational.

As a homicide court the Areopagus, under the presidency of the archon called *basileus* (king), tried cases of premeditated unjustifiable homicide. Other homicide cases went before a body of 51 jurors called *ephetai*, who may originally have been a commission of the Areopagus, but from the late 5th century B.C. onward were ordinary judges (*dikastai*). Which of these courts heard a case was probably determined by the plea of the defendant (*see* GREEK LAW).

H.)

AREQUIPA, a coastal department of southern Peru (1958 pop. est., 375,126; area 24,528 sq.mi.), bounded north by the departments of Ica, Ayacucho, Apurimac and Cuzco, east by Puno and Moquegua, southwest by the Pacific ocean. The department is made up of an arid, sandy, coastal region, cut intermittently by streams flowing from the western ranges, and a mountainous upland zone, in part of volcanic character. The climate falls within two classifications depending upon elevation: tropical desert (or arid tropical) and mountain climate. On the coast are the important ports of Matarani (completed in 1941) and Mollendo and the minor ports of Yauca, Atico and Quilca. Coastal streams include the Lomas, Yauca, Ocoña, Majes and Vitor. The northern area is watered by the Apurímac and its tributaries. The southeast of the department is traversed by the Southern railway of Peru, connecting Mollendo, via Arequipa city, with Cuzco, Puno and La Paz. The Pan American highway provides access to Chile and Bolivia.

Cotton, sugar, olives and grapes are grown in the valleys, whereas maize, potatoes and cereals are cultivated in the uplands. The latter area is also important for livestock grazing, mainly sheep, and a large quantity of wool is exported. Mineral products are gold, silver, copper, lead, coal, sulfur, manganese, rock salt, alum, borax, gypsum and kaolin clay. (J. L. Tr.)

AREQUIPA, a city of southern Peru (1958 pop. est., 121,896), capital of the department and province of the same name, stands at 8,041 ft. above sea level on the Río Chili. As a city of the Inca empire, it was an important point on the route from Cuzco to the seacoast. The city was refounded in 1540, incident to the Spanish conquest, on orders from Francisco Pizarro to establish a stronghold in this region. It was originally named Villa Hermosa de la Asunción ("beautiful town of the Assumption"). It lies in a fertile oasis amid arid uplands at the foot of El Misti, also known as El Volcán de Arequipa, an extinct volcano having a snow-capped cone 19,096 ft. above sea level. Also within view are the great peaks of Chachani (19,931 ft.) and Pichu-Pichu (18,298 ft.). Earthquakes, usually associated with volcanic activity, severely damaged the city in 1868 and 1877.

The air is dry and the climate pleasant. Rainfall is about four inches per year, and the annual average temperature is 57° F. with a range of $\pm 2.3°$ F. Flowers bloom the year around. The weather is at its best between April and September, with sunshine almost every day; the nights are generally cool. The volcanic soil of the surrounding district, watered by the Río Chili, produces cereals, grapes, sugar cane and pasturage. The abundance of water permits an intensive cultivation of crops for food and feed, most of which are consumed locally. Livestock fattened on alfalfa are exported in limited numbers. Arequipa is the great wool market of Peru, and the major part of the country's clip passes through the city, where the wool is sorted, cleaned, graded and baled. Other industries of the city include textile milling, leather, tobacco, cigarette making, brewing, printing, gold and silversmithing, soap and candlemaking, canning and flour milling. The engineering shops of the Southern railway are also there. Mineral resources of the district are gold, silver, copper, borax, mica and sulfur.

Arequipa, the political and military as well as the commercial centre of southern Peru, is located on the railway running from Mollendo to the interior. Mollendo, the seaport of Arequipa about 100 mi. distant, is also the port of entry for the Cuzco region, Lake

Titicaca and northern Bolivia. A considerable volume of traffic from northern Bolivia passes through Arequipa by way of Titicaca. A small amount of commerce reaches Arequipa by railroad from the Peruvian montaña and the eastern border valleys of the south via Cuzco. The port of Matarani competes with the older port of Mollendo as the outlet for Arequipa and these other regions.

Arequipa is an attractive city with picturesque old Spanish buildings and many interesting religious edifices constructed of "sillar," a local white volcanic stone. The houses, generally of one story, are also built of this material. The larger façades are adorned with elaborate ornament suggesting Spanish baroque. The city, being the seat of an archbishopric, has a cathedral and several historic churches, notably the Jesuit church of La Campañía, Santo Domingo, San Augustín, La Merced and San Francisco. The University of Arequipa, built in 1612, the Colegio Naciónal de la Independencia and a branch of the National Conservatory of Music have helped to keep the city in the forefront of the cultural and intellectual life of the nation. The Plaza de Armas presents a colourful spectacle, for Arequipa is the metropolis for Indians of the district. Arequipa is a popular tourist centre, and good highways provide access to the nearby resorts of Sabandia, Jesús, Socosani and other points of interest. The Pan American highway traverses the department and air service is maintained.

(J. L. Tr.)

ARES, in ancient Greek mythology, the god of war, or more properly the spirit of battle. (For the Roman god identified with Ares *see* Mars.) He may be of foreign origin, quite possibly from Thrace (*Odyssey* viii, 361). Unlike his Roman counterpart he was never very popular; his worship was not extensive in Greece except at Thebes and to a more limited extent at Athens. He represents the distasteful aspects of brutal warfare and slaughter, which he loves for their own sake. From at least the time of Homer, who establishes him as the son of Hera and Zeus, he is one of the Olympian deities, but his fellow gods and even his parents are not fond of him (*Iliad* v, 889 ff.). He is accompanied in battle, however, by his sister Eris ("Strife") and his sons Deimos and Phobos ("Panic" and "Rout"). Associated with him also are two lesser war deities: Enyalius, virtually identical with Ares himself, and Enyo, a female counterpart (*cf.* the Roman Bellona; *q.v.*). As a war god Ares has no monopoly. Both Athena and Zeus (*qq.v.*) have war attributes, which, while less sanguinary, are usually more potent. Strangely enough Ares' appearances in battle are often inglorious. In the *Iliad* he is bested by Athena and even wounded by Diomedes, a mortal. He also is bound by the Aloadae (*q.v.*), who imprisoned him for 13 months, and eventually rescued by Hermes (*Iliad* v, 385 ff.). When he tried to avenge the murder of his son, the highwayman Cycnus, Heracles wounded him and sent him off to Olympus (Hesiod, *Shield of Heracles*, 457 ff.).

Ares' worship was largely in the northern areas of Greece, where it may easily have spread from Thrace. Although devoid of the social, moral and theological associations usual with major deities, his worship has many interesting local features. At Sparta, in early times at least, human sacrifices were made to him from among the prisoners of war (a practice that had also been current in Scythia, an early seat of his worship). At Sparta also a nocturnal offering of dogs—an unusual sacrificial victim, which might indicate a chthonic deity—was made to him as Enyalius (Pausanias iii, 14, 9; Plutarch, *Roman Questions*, 290 d). During his festival at Geronthrae in Laconia no women were allowed in the sacred grove (according to Pausanias), but at Tegea he was honoured in a special women's sacrifice as *Gynaikhothoinas*, "Entertainer of Women" (also Pausanias). At Thebes he was an ancestral deity both through his daughter Harmonia, wife of Cadmus (*q.v.*), and also through another offspring, the dragon whose teeth Cadmus sowed to create the race of Thebans. At Athens he had a temple at the foot of the Areopagus ("Ares' hill"). On this hill the Areopagus council, oldest council of the Athenians, sat as a homicide court. By tradition Ares had been tried there by the gods for the murder of Halirrhothius, son of Poseidon, who had offered violence to his daughter Alcippe.

The mythology surrounding the figure of Ares is not extensive. Of interest is his association from earliest times with Aphrodite (*q.v.*). Indeed, Aphrodite is known locally (*e.g.*, at Sparta) as a war goddess, apparently an early facet of her character. Undoubtedly an original religious connection gave rise to later myths linking the two romantically. The most famous story of their relationship is humorously recorded in *Odyssey* viii. The husband of Aphrodite, Hephaestus, caught the pair *in flagrante delicto*, cast an invisible net over them and summoned all the other gods to witness their shame, causing great hilarity on Olympus. According to some versions it is the jealous Ares who, disguised as a boar, slew Aphrodite's beloved Adonis. Occasionally (*e.g.*, at Thebes) Aphrodite is his legitimate wife. By Aphrodite he fathered Deimos and Phobos and Harmonia (*see* above). He is sometimes also the father of Eros and Anteros. By Aglauros, the daughter of Cecrops (*q.v.*), he was the father of Alcippe. He was the sire of at least two of Heracles' adversaries: Cycnus and Diomedes of Thrace.

The artistic representations of Ares are not numerous. One of the earliest is on a fragment of a Lemnian vase of the 8th century B.C. depicting the affair with Aphrodite described above. On vases he is usually the typical armed warrior. There were statues by Alcamenes, Scopas and Leochares, but extant works (*e.g.*, Ares Ludovisi and Ares Borghese) are mostly Roman and cannot successfully be identified with Greek originals. The Parthenon frieze contains a group of Olympians, among whom Ares, in unwarlike garb, has been tentatively identified. He also appears on the great frieze of the altar at Pergamum.

Harrison, *Prolegomena to the Study of Greek Religion* (1922); O. Kern, *Religion der Griechen*, vol. i (1926); H. J. Rose, *Handbook of Greek Mythology* (1953). (R. B. Ld.)

ARETAEUS of Cappadocia, a Greek physician, who lived at Rome in the second half of the 2nd century A.D. Two treatises by him are extant, each in four books, in the Ionic dialect: *On the Causes and Indications of Acute and Chronic Diseases*, and *On Their Treatment*. Aretaeus' work was founded on that of Archigenes; like him, he belonged to the eclectic school, but he did not ignore the theories of the "pneumatists," who asserted that life is associated with vital air, or pneuma.

ARETHUSA, in Greek mythology, a nymph who gave her name to a spring in Elis and to another in the island of Ortygia near Syracuse. The river god Alpheus fell in love with Arethusa, one of the retinue of Artemis; Arethusa fled to Ortygia, where she was changed into a spring; Alpheus made his way beneath the sea, and united his waters with those of the spring. In Ovid's *Metamorphoses* Arethusa, while bathing in the Alpheus, was seen and pursued by the river god in human form; Artemis changed her into a spring which, flowing underground, emerged at Ortygia.

In an earlier form of the legend, it is Artemis, not Arethusa, who is the object of the god's affections, and who escapes by smearing her face with mire, so that he fails to recognize her. The story probably originated from the fact that Artemis Alpheiaia was worshiped in both Elis and Ortygia, and also that the Alpheus in its upper part runs underground, as is confirmed by modern explorers. In Virgil's *Eclogues* Arethusa is addressed as a divinity of poetical inspiration, like one of the Muses, who were themselves originally nymphs of springs.

ARETHUSA (*Arethusa bulbosa*), a common North American plant of the orchis family, found in bogs and swampy regions during May and June from Newfoundland south to North Carolina and west to Indiana and Minnesota. The flowers are magenta-crimson, having a crest formed of three hairy ridges, white or yellow in colour, and with a lower lip spotted with magenta. They grow on single stalks five inches to ten inches in height. The leaves appear after the flowers open and are long, narrow and single. The root is bulbous. A common name for arethusa is Indian pink.

ARETINO, PIETRO (1492–1556), Italian author who wrote in unconventional language and who has been described as the first "journalist" of his century, was born in 1492 at Arezzo. Thence he called himself "Aretino"; the name of his family is

unknown. When still very young he went to Perugia, where he practised painting, then to Rome, where he published some scandalous *pasquinate* (satirical poems), and finally to Venice (1527), where he remained until his death in 1556. There he found the appropriate milieu for using his pen as a means for blackmailing rulers (Ariosto called him "the scourge of princes"). The six volumes of his letters (1537–57) are evidence of his power and cynicism. His realistic *I Ragionamenti* (2 parts; 1534–36), written in dialogue form, show his sensual and unscrupulous nature as well as his colourful style. Of lesser interest are his poems and religious writings. He also wrote a remarkable tragedy, *Orazia* (1546) and five comedies (1525–42). He had great influence on some 16th-century writers, but to modern readers he is mainly important as a moral phenomenon of his times.

Il I e il II libro delle Lettere di Pietro Aretino was edited by F. Nicolini (1913–16) and *I Ragionamenti* by D. Carraroli (1914); an edition of the *Commedie di Pietro Aretino, aggiuntavi l'Orazia* was published by E. Camerini (1876) and another *Commedie*, by N. Macarone (1914).

Bibliography.—C. Bertani, *Pietro Aretino e le sue opere* (1901); G. M. Mazzuchelli, *La vita di Pietro Aretino* (1741); K. Vossler, *Pietro Aretinos künstlerisches Bekenntnis* (1900); E. Hutton, *Pietro Aretino, the Scourge of Princes* (1922); T. C. Chubb, *Aretino, Scourge of Princes* (1940); A. del Vita, *L'Aretino* (1954). (G. A.)

AREZZO, a city and capital of Arezzo province, north central Italy, lies in a fertile plain in eastern Toscana near the junction of the Chiana and Arno rivers, 54 mi. (87 km.) by road southeast of Florence. Pop. of commune (1961) 75,209. The medieval walls almost completely surround the city, the oldest part of which is built on a hill 1,053 ft. high. On its summit stands the Fortezza Medicea, built in 1541–69 by Antonio Sangallo (*q.v.*). The splendid Piazza Grande close by was once the city centre; the sides of the square are formed by a variety of palaces and houses dating from the 14th century among which are the Palazzo delle Logge, with open balconies, by G. Vasari, the Palazzo della Fraternità of mixed styles, the Palazzo del Tribunal by R. Cerrotti, and the Palazzo Pretorio (14th century), decorated with coats of arms on the façade and five Renaissance windows, and now containing the public library. The Giostra del Saracino, a tournament dating from the 13th century, is held every year in the Piazza Grande between June and September. The Gothic cathedral was begun in 1286 and finally completed in 1914. The Romanesque church of Sta. Maria della Pieve, which backs on to the Piazza Grande, contains a beautiful polyptych by Pietro Lorenzetti. The church of S. Domenico (13th–14th century) contains a crucifix painted on wood by Cimabue. These and the Renaissance churches of Sta. Maria delle Grazie and SS. Annunziata (by Sangallo) bear witness to the city's splendid past, but of the greatest importance is the work of Piero della Francesca (*q.v.*) seen in his series of frescoes depicting the "Legend of the True Cross" in the church of S. Francesco. This church also contains a series of frescoes by Spinello Aretino, a native of Arezzo. In the town are remains of a Roman amphitheatre, and the Etruscan museum and the Pinacoteca contain many rare objects and works of art.

Arezzo was the home of Francesco Petrarch (1304–74), Pietro Aretino, Giorgio Vasari (1511–74) and Guido of Arezzo (d. 1050) (*qq.v.*).

Arezzo is a centre of road communications. Its economy is basically agricultural, but the goldsmiths export their goods throughout Europe and there are clothing and footwear factories.

The city, already important in Etruscan days, was known to the Romans as Arretium. In the middle ages it was a flourishing town which fell to Florence in 1384. Later it became part of the grand duchy of Tuscany. After a short period of French rule in the early 19th century it became part of the Italian kingdom in 1861. It was severely damaged during World War II and was captured by the Allies in July 1944. (D. Os.)

ARGALI, the largest living wild sheep, *Ovis ammon* and its many races, found in the highlands of east central Asia. It may stand four feet high at the shoulders and weigh over 300 lbs. Large horns, present in the rams, are especially massive in the Pamir argali, or Marco Polo sheep, in which they may be 70 in. or more in length. *See* Sheep.

ARGAND BURNER, the first scientifically constructed oil burner, was invented by Aimé Argand of Geneva in 1784. It consisted of a cylindrical wick confined between two concentric tubes; this device gave a circular flame with a current of air brought to play upon its inner surface. A glass chimney increased the draft and improved the illumination. William Murdock, the pioneer of gaslighting, adapted the Argand idea of two concentric circular pipes in the designing of gas burners.

See Lighting: *Gas*.

ARGEI, the name given by the ancient Romans to a number of rush puppets (24 or 27), resembling men tied hand and foot, which were taken down to the ancient bridge over the Tiber on May 14 by the *pontifices* and magistrates, with the wife of the Flamen Dialis in mourning guise, and there thrown into the Tiber by the Vestal virgins. There were also in various parts of the four Servian regions of the city a number of *sacella Argeorum* (chapels), round which a procession seems to have taken place on March 17, and where the puppets were probably kept until the second procession.

The Romans had no historical explanation of these curious rites, and the theory of the common people that the puppets were substitutes for old men who used at one time to be sacrificed to the river is not generally accepted. Various explanations have been suggested by scholars.

ARGELANDER, FRIEDRICH WILHELM AUGUST (1799–1875), German astronomer, famous for his great catalogue in which are determined the positions of thousands of stars, was born at Memel, then in East Prussia, on March 22, 1799, and studied at Königsberg, where he was later the successor of F. W. Bessel. Argelander was appointed director of the Åbo observatory in 1823 and of the Helsinki observatory in 1827. In 1837 he published the first major investigation of the sun's motion in space, which had been previously pointed out by Sir Frederick William Herschel, and in the same year he was appointed director of the new Bonn observatory. His greatest achievement was the publication of the *Bonner Durchmusterung* (1859–62), which catalogues the position and brightness of nearly 325,000 stars from the north celestial pole to 2° S. of the celestial equator and which was completed after 25 years' continuous work. The corresponding atlas was issued in 1863. The importance of this work is indicated by the fact that it was, by demand, reissued in 1950. In 1844 Argelander drew attention to the importance of variable stars, of which there were then only six known. His method of visual estimation of the brightness of stars—the "step method"—is still in general use. His treatise on the comet of 1811 appeared in 1822 and his subsequent observations fill the first seven volumes of the *Durchmusterung*. He died at Bonn, Ger., on Feb. 17, 1875.
(O. J. E.)

ARGENS, JEAN BAPTISTE DE BOYER, Marquis d' (1703–1771), French novelist and occasional writer, who helped to disseminate the ideas of the *philosophes*, was born at Aix-en-Provence on June 27, 1703, of a noble family. He traveled in Spain, Turkey and Italy in his youth, leading a life of dissipation. Settling thereafter first in the Netherlands, then at the Prussian court, he devoted himself to literature. He produced a number of works inspired by Montesquieu's *Lettres persanes*, the most important being his *Lettres juives* (1736–38), *Lettres cabalistiques* (1737) and *Lettres chinoises* (1739–40). His *Philosophie du bon sens* (1737), a well-written work of popularization, owes much to Bayle and Fontenelle, and stimulated French interest in Locke. The best-known novel attributed to him is the scurrilous but often reprinted *Thérèse philosophe* (1748). He was a friend of D'Alembert and Voltaire, and a protégé of Frederick the Great. He died at Toulon on Jan. 12, 1771.

See E. Johnston, *Le Marquis d'Argens* (*c.* 1928) and D'Argens' own *Memoires*, ed. by L. Thomas (1941). (Rt. S.)

ARGENSOLA, LUPERCIO LEONARDO DE (1559–1613), Spanish dramatist and poet, was baptized at Barbastro, on Dec. 14, 1559. He was appointed historiographer of Aragon in 1599, and in 1610 accompanied the count de Lemos to Naples, where he died in March 1613. Between 1581 and 1585 he wrote three romantic tragedies—*Filis* (lost), *Isabela* and *Alejandra* (the

two latter printed in 1772). These are uninspired imitations of Seneca, dealing with Christian subjects and showing Italian influence. They were praised by Cervantes, Lope de Vega and Vicente Espinel. His poems were published with those of his brother in 1634; they consist of odes, sonnets, *canzoni*, satires and translations from Latin, some being of high quality.

His brother BARTOLOMÉ LEONARDO DE ARGENSOLA (1562–1631), Spanish poet and historian, was baptized at Barbastro on Aug. 26, 1562. He was attached to the suite of the count de Lemos, viceroy of Naples, in 1610 and succeeded his brother as historiographer of Aragon in 1613. He died at Saragossa on Feb. 4, 1631. His principal prose works are the *Conquista de las Islas Molucas* (1609), and a supplement to J. Zurita's *Anales de la Corona de Aragon*, published in 1630. He was a gifted and skilful poet. (J. Gs.)

ARGENSON, the name of a French noble family from Touraine, prominent in national affairs in the 18th and in the first half of the 19th century.

MARC RENÉ DE VOYER, marquis de Paulmy and marquis d'Argenson (1652–1721), was born in Venice on Nov. 4, 1652. After holding a succession of legal offices at the French court, he was in 1697 appointed lieutenant general of police of Paris. In 1718 he was made keeper of the seals by the regent, Philippe duc d'Orléans, who wanted him to break the opposition of the *parlement* of Paris to John Law's financial system. He was also made temporary president of the council of finance. In fact he joined forces with the opponents of Law and found himself obliged to resign in 1720. He died in Paris on May 8, 1721.

BIBLIOGRAPHY.—H. M. Leclercq, *Histoire de la Régence*, 3 vol. (1922); P. Cottin (ed.), *Rapports inédits du lieutenant de police René d'Argenson* (1891); P. Clément, *La Police sous Louis XIV* (1866).

RENÉ LOUIS DE VOYER DE PAULMY, marquis d'Argenson (1694–1757), was born in Paris on Oct. 18, 1694, the oldest son of Marc René, and was also a member of the legal profession. Between 1720 and 1724 he served as intendant in Hainaut. Returning to Paris, he became a patron of the Club de l'Entresol, in which, through discussions with Voltaire and Viscount Bolingbroke, he learned to think deeply about political problems. He was also influenced by the ideas of Charles Irénée Castel, abbé de Saint-Pierre (*q.v.*), and, having been appointed minister of foreign affairs in Nov. 1744, tried unsuccessfully to implement his own doctrinaire schemes for international arbitration. His plans were directed against France's ally Spain, whose influence in Italy was to be undermined by a confederation of the Italian states; against Austria, whose preponderance in Germany was to be counterbalanced by alliances with Prussia and with Saxony; and against Russia, which was to be held in check by a league of Baltic states. These schemes were frustrated by the secret diplomacy of Louis XV and by court intrigue. D'Argenson's persistence in his ideas was a major factor in prolonging the War of the Austrian Succession (*q.v.*) after he had failed to prevent the election of Maria Theresa's husband Francis as emperor in 1745. In Jan. 1747 he was compelled to resign. As president of the Académie des Inscriptions he spent the rest of his life in literary pursuits. His *Journal et Mémoires* (published in 1859) form one of the major sources for the literary and political history of Louis XV's reign, while his *Considérations sur le gouvernement ancien et présent de la France*, with its suggestion that municipal and provincial assemblies should be revived, had great influence on physiocratic schemes for the reform of local government under the *ancien régime*. He died in Paris on Jan. 26, 1757.

MARC PIERRE DE VOYER DE PAULMY, comte d'Argenson (1696–1764), born on Aug. 16, 1696, the younger brother of René Louis, held office as lieutenant general of police, as intendant in Touraine, as *conseiller d'état* and as secretary of state for war. He was responsible for the foundation of the École Militaire in 1751. Like his brother, he was a patron of the *philosophes*, and Denis Diderot dedicated to him the first volume of the *Encyclopédie*. He spent the last six years of his life in exile from the court, after being dismissed through the influence of Madame de Pompadour. He died in Paris on Aug. 22, 1764.

MARC ANTOINE RENÉ DE VOYER (1722–1787) was born at Valenciennes on Nov. 22, 1722, the son of René Louis. He served as ambassador to Switzerland (1749–51), to Poland (1759–65) and to Venice (1766–70). After retirement he occupied himself with literary and historical studies and collected one of the finest private libraries in Europe; sold in 1785 to the comte d'Artois, the future Charles X of France, it became the nucleus of the Bibliothèque de l'Arsenal in Paris. He died in Paris on Aug. 13, 1787.

MARC RENÉ, marquis de Voyer (1722–1782), the son of Marc Pierre, was born in Venice. He fought in the War of the Austrian Succession and in the Seven Years' War and was later military governor in Saintonge and Poitou. He died at Ormes Saint-Martin in Poitou on Sept. 16, 1782.

MARC RENÉ, marquis d'Argenson (1771–1842), the son of the last-named, was born in Paris on Sept. 19, 1771. He embraced the principles of the French Revolution and entered the army in 1791, becoming aide-de-camp to Lafayette. However, after the latter's defection, he retired to his estates in Poitou and took up scientific agriculture. Between 1809 and 1813 he was prefect of the *département* of Deux Nèthes (Antwerp) and helped to repel the British invasion of Walcheren. After 1815 he devoted himself to the cause of liberalism in the chamber of deputies and under the July monarchy was a member of the republican opposition. He died in Paris on Aug. 1, 1842. (A. GN.)

ARGENTEUIL, a town in northern France in the *département* of Val-d'Oise, lies on the north bank of the Seine, 8 mi. (13.5 km.) N.W. of Paris. Pop. (1962) 82,007. Argenteuil grew up around a monastery, originally (7th century) a convent in the village of Parisis. A daughter of Charlemagne was possibly abbess of the convent, which later received *Heloïse* (*see* ABELARD, PETER); she became prioress, but was expelled in 1129 and the convent was made a monastery. Enshrined in its church is *la Sainte Tunique*, claimed to be the seamless robe of Christ, given to the convent by Charlemagne. After World War I the growth of industry (metallurgy, electrical manufacture, aircraft construction, artificial silk) and the increase in its residential area caused what had been a village to rank as a town. The district has long been celebrated for its vineyards, representations of which are in the museum, and the first Sunday in October is still kept as the feast of the wine harvest. Fruit and vegetable growing, especially asparagus, is still a minor activity. (H. DE S.-R.)

ARGENTINA (REPÚBLICA ARGENTINA), a country occupying most of the southern part of the continent of South America, is shaped like a wedge with the point toward the south. The length of Argentine territory from north to south is 2,294 mi.; its greatest width is about 884 mi. The area is 1,072,067 sq.mi., not including the Falkland Islands (*q.v.*), various lesser islands in far southern waters, and a 49° sector of Antarctica of about 475,000 sq.mi. to all of which Argentina lays claim. The population was 20,008,945 in 1960. On the north and northeast the country adjoins Bolivia, Paraguay, Brazil and Uruguay, with the Pilcomayo, Paraguay, Paraná and Uruguay rivers constituting the greater part of the boundary itself. Argentina is bounded on the west and south by Chile and on the east and southeast by the Atlantic ocean. The capital is at Buenos Aires (*q.v.*).

This article is divided into the following sections and subsections:

There are separate articles on all the Argentine provinces and territories and on the more important cities.

I. PHYSICAL GEOGRAPHY

The Republic of Argentina includes a wide variety of kinds of land. From the point of view of geology and surface features there are four different physical divisions: (1) the Andes; (2) the alluvial plains east of the Andes; (3) a small piece of the Paraná plateau; and (4) the plateaus of Patagonia. These differentiate the national territory into contrasted kinds of terrain; but there are also great climatic contrasts, and the climates are reflected in the pattern of vegetation. The far north of Argentina is north of the Tropic of Capricorn at 21° 46′ 55″ S.; the far south of Argentina in Tierra del Fuego is 55° 03′ 30″ S. Parts of the national territory receive abundant rainfall, but a large part of the area is very arid.

1. **Geology and Structure.**—*The Andes.*—The Andes mountains form the greater part of the western border of Argentina. About as far south as latitude 36° S. the Andes are very high; the pass routes over the ranges are over 10,000 ft. above sea level. As far as 27° S. the mountains are made up of numerous high intermontane basins separated by short but steep-sided ranges. In this part of the Andes there are two major cordilleras. The western one lies generally within Chile; the eastern one is a southward continuation of the Eastern Cordillera of Bolivia. Essentially the Andes are a huge block of the earth's crust underlain by folded and faulted sedimentary formations mostly Mesozoic and Tertiary. The block is lifted on the west and tilted toward the east. Its surface, especially in the west where it is little dissected, is remarkably level at the higher altitudes, but is surmounted by numerous small ranges running more or less in a north-south direction. Toward the east the rivers have cut long fingers of canyons back into the high country, and near the eastern margin of the range the whole surface is sharply dissected by the streams. The steep-sided valleys separated by sharp-crested ridges are known as *quebradas.* Along the eastern margin of the mountains there is a zone of front ranges, tilted cuestas (ridges) of sedimentary strata that face toward the mountains and slope more gently toward the eastern plains. Between the cuestas are long, parallel valleys. These front ranges continue southward as far as Tucumán.

At about latitude 27° S. the character of the Andes changes. Running southward there is only one single commanding range. In Argentina between Tucumán and about latitude 36° S. discontinuous desert ranges push out east of the main range into the eastern plains, holding between them a number of typical desert bolsons. The main range reaches its highest point to the west of Mendoza in Mt. Aconcagua (*q.v.*), 22,831 ft., loftiest in the western hemisphere. As far as 36° S. the passes over the main range are all very high. Glaciation, however, was more and more vigorous toward the south during the glacial period. The mountains take on the characteristic forms of glaciated mountains: cols, horns, cirques, glacial troughs and hanging valleys. The glaciers gouged out the valleys so that south of 36° S. the passes are all low. South of 46° S. the Andes are still covered with near icecaps, and glaciers descend to the heads of the fiords on the Chilean side and to the ends of the glacial lakes on the eastern side. During the glacial period the ice spread out to the east of the mountains in southern Argentina, as far as the Atlantic ocean along the Strait of Magellan. In the southern Andes, before the glacial period, rivers draining westward to the Pacific had cut back through the heart of the range so that the drainage divide was actually east of the Andes. When the ice invaded these valleys the drainage was blocked, and for a time the rivers drained eastward to the Atlantic. Large lakes were formed where the ice blocked the outlets to the Pacific. At the present time two lakes—Viedma and Argentino—are still blocked by ice and drain eastward, but all the other lakes drain westward. The fact that the highest crest of the Andes and the drainage divide are not the same gave rise to an important boundary dispute between Chile and Argentina. (*See* also ANDES.)

Alluvial Plains.—The second of the chief physical regions of Argentina includes the great alluvial plains that stretch out eastward from the base of the Andes from about latitude 38° S. northward. A deep accumulation of debris brought down by the rivers from the erosion of the Andes has been spread out like a great sheet to the east. In northern Argentina the slope eastward is scarcely perceptible. Rivers, such as the Pilcomayo and the Bermejo, meander in shifting channels across the alluvial plains, spreading out in extensive floods during the rainy season (October to April) and then forming braided channels with many sand bars during the dry season. The water table is not far below the surface in this part of Argentina, yet finding surface water in dry season may be difficult. The similarity of these plains to the Ganges valley of India is striking.

All the drainage of this area is gathered by the Río Paraguay-Paraná-Plata (*see* PLATA, RÍO DE LA). But south of the Río Carcarañá, which carries the drainage from the Sierra de Córdoba to the Paraná, no major streams reach the sea. This is the Argentine humid pampas (Spanish *pampa*), a deep accumulation of alluvial material (985 ft. deep at Buenos Aires) overlain by a layer of fine, wind-blown dust or loess brought by the westerly winds from the deserts of Patagonia. Two ranges of low mountains protrude through the covering of alluvium and loess: (1) the Sierra del Tandil is 1,772 ft. above sea level; (2) the Sierra de la Ventana is 4,078 ft. high. Around the base of each of these ranges and of the Sierra de Córdoba (an outlier of the Andes) there is an apron of alluvial material. At Córdoba, which is built at the base of the mountains on this alluvial apron, the elevation is 1,300 ft. above sea level. The greater part of the pampas, however, stands only 100 ft. or so above the sea, and its surface is so nearly level that drainage is poor. The soil is entirely free from pebbles.

So great is the volume of alluvium supplied to the Río Paraná that this main drainage line has certain notable peculiarities. Downstream from Posadas, where the Paraná emerges from the Paraná plateau, the river is braided and shifting. At the high-water period the floods cover the whole of the flood plain, in some places more than 30 mi. wide; but at low water, sand bars clog the channels, and the river is split into a maze of minor rivulets. The main channel often shifts from one season to the next, with disastrous results for river ports. River boats must make many miles of sailing around the meanders to make only a short distance in a direct line. When the Paraná is joined to the Uruguay to make the Plata there is a wide swampy zone threaded by many small channels. The main channel of the Plata is near the Uruguay shore. Between it and the Argentine shore on either side of Buenos

Aires there is a wide zone of shallow water; and when the southwest wind is especially strong the water is blown northward, revealing the wide area of mud flats. Constant dredging is required to keep the port of Buenos Aires open.

Paraná Plateau.—A small part of Argentine territory is included within the area of the Paraná plateau. This is the territory of Misiones, which extends like an arm between Paraguay and Brazil. The Paraná plateau is made up of successive flows of diabase lava. This rock is so resistant to the forces of erosion that it stands up with cliffs, and the rivers descend from the plateau in great falls, such as the Guaíra falls or the Iguaçu falls (*q.v.*), or in long stretches of rapids, as along the Río Uruguay. Between the rivers the plateau surface is flat-topped.

Patagonia.—Patagonia is the general regional name given to the part of Argentina south of the Río Colorado at about latitude 40° S. The whole width of the country east of the Andes is occupied by a series of steplike plateaus rising from the edge of the ocean, where cliffs make landing difficult. The plateau steps rise toward the west, the highest being well over 5,000 ft. above sea level. The plateaus are formed on nearly horizontal sedimentary strata, mostly sandstones. In northern Patagonia crystalline rocks emerge from the sedimentary cover; where they do so, they hold up low hills that stand somewhat above the level of the plateaus. The plateaus are crossed by a succession of deep canyons, steeply cliffed on the sides and flat-bottomed. These canyons carried the drainage from the west during the glacial period, but now the amount of water in them has been much reduced. Along the eastern front of the Andes the west-flowing rivers have excavated a discontinuous belt of lowlands, known as the pre-Andean depression, between the westernmost plateau and the mountains.

The Patagonian coast generally lacks harbours. In the south, however, there are embayments such as those on which Santa Cruz and Puerto Gallegos are situated. But the utility of these places as ports is reduced by the great tidal range—as much as 48 ft. in the spring tide. (*See* also PATAGONIA.)

2. Climate.—*Temperature.*—The territory of Argentina extends approximately from latitude 22° S. to 55° S. A similar position in the northern hemisphere would include the area between Cuba and Hudson bay. Since most of the Argentine territory lies within the middle latitudes, temperature extremes and great weather variability might be expected. In North America the range of temperature between summer and winter increases toward the north; at Edmonton, in Alberta, a little less than 55° N., the average monthly temperatures range from 5.5° F. in January to 61.1° in July, a range of near 56°. No such differences between summer and winter are found in South America because the continent tapers sharply toward higher latitudes and the ocean has the effect of moderating the temperatures. Ushuaia, Argentina's southernmost town at about 55° S., ranges from 33.3° in June to 49.6° in January, a range of only a little over 16°.

Cool summers and mild winters characterize all of Argentina as far north as the Río Negro valley in northern Patagonia. Cool summers also are experienced in the exposed easternmost part of the humid pampas, which is bathed by the cold Falkland Island current. At Mar del Plata, for example, the warmest month averages only 66.9°.

On the other hand, very hot summers are experienced throughout the northern part of Argentina. At Santiago del Estero, for example, the temperature averages 83.1° in January, higher than any place in the low latitudes. North of Santiago del Estero in the Chaco is the only area in South America in which temperatures of 110° and over are experienced. In this same area the average temperature of the coldest month is about 56°. At Buenos Aires, located a little south of latitude 34° S., the average temperature in January is 73.6°, compared with an average of 81.4° in Charleston, S.C., in July. The average temperature in July at Buenos Aires (48.9°) is about the same as that in January at Charleston (49.8°). In other words, compared with places at about the same latitude in eastern North America, Buenos Aires has winters of about the same average temperature and summers that are not nearly so hot. Actually the average summer temperature in Buenos Aires is similar to that in New York city, at about latitude 40° N.

Frosts occur occasionally in almost all parts of Argentina except the far north. In every winter there are frosts in Patagonia. In the northern part of the humid pampas the length of the frost-free season is about 300 days. Tucumán is located in a small frost-free "island" where the low temperatures of winter nights are moderated by a cloud cover. Farther away from the mountains, where night skies are clear, frosts occur every winter, even well to the north of Tucumán.

Rainfall.—A very large part of Argentina is arid or semiarid. Abundant year-round rainfall is found only in southernmost Tierra del Fuego and in the northeast, north of Bahía Blanca. The line between semiarid and humid climates runs north and south through the Chaco a little to the east of Santiago del Estero. It passes a little to the west of Córdoba and reaches the Atlantic coast just south of Bahía Blanca. The rainfall of the humid pampas is evenly distributed throughout the year. At Buenos Aires, for example, the average annual rainfall is 37 in.; the driest month, June, receives an average of 2 in., and the rainiest month, April, receives 4.8 in. But the interior of the northeast, in the Paraguay-Paraná valley north of Santa Fe, has most of its rain in summer. In that region the rainiest month is January or February, averaging more than five inches; the driest month is June, averaging less than an inch.

The belt of aridity in South America crosses the Andes in southern Bolivia and northern Argentina. South of latitude 20° S. the dry belt extends over the plains east of the Andes. Mendoza averages only 7.7 in. Dry conditions extend southward through Patagonia to the Strait of Magellan. The average rainfall at Santa Cruz, for example, is only 5.5 in. North of the Río Negro the desert is hot and sunny; in Patagonia it is cool and often cloudy.

Weather.—All of Argentina has changeable weather. The storms in this part of the world are brought by polar outbursts (cold air masses) emerging from the antarctic continent. The cold waves cross the South Pacific ocean, where the temperatures

EWING GALLOWAY

IGUAÇU FALLS, ONE OF ARGENTINA'S GREAT NATURAL WONDERS, LOCATED ON THE ARGENTINA-BRAZIL BORDER

are moderated especially in the lower layers. Unstable and moisture-laden, these air masses bring heavy rains to the west coast of southern Chile. The Andes, however, keep most of this moist air from reaching Argentina, except for a few spots where the rain spills over to the eastern side of the mountains through the deeply cut valleys. Some of the cold air masses reach the continent of South America east of the Andes, setting up cyclonic whirls of air along the advancing cold fronts. The cyclones rotate clockwise in the southern hemisphere. But even when northerly winds reach Patagonia, they must travel over wide expanses of cold water off the east coast of the continent (Falkland Island current). The result is that the Patagonian weather is characterized by shifting, blustery winds, by rolls of gray cloud, but little rain or snow. The typical Patagonian landscape is indistinct and hazy because of the great quantities of dust picked up from the desert surface by the violent winds.

Winds.—The common winds of Argentina are given special names. The cold air masses advance from the south or southwest, and this wind is known as the pampero. The warm, muggy air on the front of the advancing cold air, coming from the north, is known as the *norte*. When a cold air mass spills over the Andes and descends as a warm and dry air mass on the eastern side (a typical chinook or foehn), the Argentines speak of it as a *zonda*. Each of these winds brings weather that is familiar to people in North America. Anyone who has experienced the parching effect of a chinook in the plains east of the Rocky mountains would find nothing strange about the *zonda*. The warm, depressing weather associated with a cyclonic storm is brought by the *norte*. The cold front gives rise to thunderstorms and tremendous displays of lightning, after which the pampero brings clear and bracing weather.

3. **Vegetation.**—The various climatic features are reflected in the cover of natural vegetation. Where rainfall is abundant there are forests. Where rainfall is less abundant there are woodlands, consisting of low, scrubby trees. Where rainfall is insufficient there are deserts. And in the humid pampas there is a tall grassland, apparently a man-made formation.

The alluvial plains in northern Argentina, between the Andes and the Paraguay-Paraná, are covered with a scrubby deciduous woodland and with patches of savanna. This is the region known as the Gran Chaco (*q.v.*) or the "hunting ground." There are places where thorny deciduous trees grow so close together that they form almost impenetrable thickets. In other places, especially near the rivers, there are belts of tall trees—the semideciduous tropical forest characteristic of the regions farther north. There are places where the scrubby trees are widely spaced and there is grass on the woodland floor. And there are places where, unaccountably, the woodland is interrupted by patches of pure savanna. Throughout this Chaco woodland are found different species of the red quebracho tree or *quebracho colorado* (*Schinopsis*), a source of tannin. *Schinopsis lorentzi* is found chiefly in the eastern part of the Chaco along the western side of the Paraguay-Paraná. It occurs in dense stands only in those places where the ground water is salty. In the western part of the Chaco is found *S. balansae*, which contains much less tannin but which is of great value for firewood and for fence posts. The Chaco woodland contains few other commercially valuable species.

The southern limit of the Chaco woodland is roughly the valley of the Río Salado, which enters the Paraná near Santa Fe. To the south a woody xerophytic scrub, known in Argentina as *monte*, occupies the semiarid areas. The drier parts of the country have only scattered xerophytic shrub, with bare ground between the plants. Only where streams descend from the mountains was there originally a dense growth of *monte*, which has now been cleared away to make room for irrigated crops.

When the Spaniards first arrived on the shores of the Plata in the early 16th century they found an apparently endless sea of tall, plumed grass, grass that grew so high in the rainy season that to see out over it a man had to stand on the back of his horse. The grasses of the pampas grow in bunches in the better-drained spots, and the many wet spots on the pampas were covered with coarse marsh grasses. The geographer Oscar Schmieder, who

BY COURTESY OF DIRECCION NACIONAL DE TURISMO, REPUBLICA ARGENTINA

ARAUCARIA PINE IN THE ANDEAN LAKE REGION

studied the region intensively, reached the conclusion that the original vegetation of most of the pampas was probably the same kind of scrubby, woody plants (*monte*) found farther west and farther north. Perhaps grass was mixed with the woody plants. A very small population of hunting Indians, who set fire to the grass just before the beginning of the rainy season in order to round up the game, could have created a pure grassland. Fire has the effect of killing the woody plants, leaving the grasses to grow each year without competition. The Spaniards introduced cattle and horses to the part of the pampas along the Paraná-Plata shore between Buenos Aires and Santa Fe, and unintentionally they brought the seeds of European grasses. In a short time the whole northeast part of the pampas was covered with European grasses that formed a thick sod instead of growing in bunches. As long as cattle grazed, or fires raged, the woody plants were kept out of the pampas. Yet ornamental trees planted around estate headquarters grew without difficulty.

The grasslands continue northward into the part of Argentina that lies between the Paraná and Uruguay rivers and eastward into Uruguay and south Brazil. But where the arm of Argentine territory is extended northward along the eastern side of the Paraná onto the Paraná plateau the grasslands give way to forest. In the deeper valleys, protected from frosts, is found a tropical semideciduous forest. On the plateau surface is a forest consisting of *Araucaria* pine mixed with broadleaf deciduous trees.

In Patagonia the desert surface is covered with xerophytic shrub. Drought-resistant low shrubs fight for existence in the face of aridity and high winds. Some ribbons or islands of *monte* occupy canyon bottoms and sheltered spots in the lee of cliffs. On the higher plateaus, where a thin blanket of snow falls each winter, there is a quick-maturing growth of short grass in the spring. A short grass steppe runs in the belt along the eastern Andean piedmont, the pre-Andean depression, where the rainfall is somewhat greater than it is farther to the east. In southern Tierra del Fuego the lower mountain slopes are covered with the Chilean evergreen broadleaf forest. (P. E. J.)

4. **Animal Life.**—Many tropical animals enter northern Argentina in the forests and marshes of the Paraguay and Paraná basins. These include the howling monkey, tapir and marsh deer, giant anteater and jaguar and the largest of rodents, the aquatic capybara, with the still more aquatic coypu. The great variety of grassland and desert animals gives the Argentine fauna its special character. Most conspicuous are the guanaco (the wild cameloid

ancestral of the llama) and the ostrichlike rheas. Large and small rodents in vast numbers and considerable variety characterize the plains.

The Patagonian cavy (*Dolichotis*) is long-legged and graceful. The viscacha (*Lagostomus*), about 30 in. long, is a gregarious burrower, and its colonies attract a wide variety of other animals (including birds), much as do those of the North American prairie dog. The small tuco tuco everywhere riddles the soil. The hairy armadillo, the three-banded armadillo and the molelike and mole-sized pichiciago of the Andean deserts are characteristic. The puma is the most widespread carnivore. Azara's fox and the hog-nosed skunk are ubiquitous.

The condor (*Vultur gryphus*) glides majestically through the bleak valleys of the high Andes. The largest of the plains birds, next to the rhea, is the crested screamer. Native and migrant shore birds are numerous. The various kinds of tinamous, with wailing voice and eggs like purple porcelain, are known as *perdiz*. The ovenbird with its mud nest is everywhere conspicuous.

Caymans, turtles, lizards, small snakes and a few types of frogs are present. A magnificent game fish, the dorado, is found in the larger streams. (K. P. S.)

II. GEOGRAPHIC REGIONS

The national territory of Argentina may be divided into five major geographic regions: (1) the northwest; (2) the Chaco; (3) Mesopotamia; (4) Patagonia; and (5) the humid pampas. The first four regions are all oriented toward the humid pampas in the economic and social life and in the institutions of government. In the humid pampas, and especially in the "Great City" of Buenos Aires, is concentrated most of the productive capacity of the nation.

1. Northwest.—The northwest includes the Andes and the eastern piedmont of the Andes north of the Río Colorado, or about latitude 36° S. It includes all or part of the following provinces: La Pampa, Mendoza, San Luis, San Juan, La Rioja, Catamarca, Tucumán, Salta and Jujuy (*qq.v.*).

This was the first section of what is now Argentina to be settled by the Spaniards. The people who came to this part of the continent came directly or indirectly from Peru, and their economic connections during most of the colonial period remained oriented toward Lima and the silver-mining communities of the Andes. Santiago del Estero was founded in 1553. Other settlements in the region were made soon after: Tucumán in 1565; Salta in 1582; La Rioja in 1591; Jujuy in 1593. Settlers from Santiago del Estero also occupied the site of Córdoba in 1573. Meanwhile the piedmont towns farther south had been settled by people from Chile: Mendoza in 1561–62, San Juan in 1562 and San Luis in 1596. During most of the colonial period Tucumán was the major focus of all the country east of the mountains. There the mules from the humid pampas were concentrated and fitted with pack harness before being driven to the annual fair held at Salta. Only after Argentina became an independent country were these economic connections gradually broken.

The economic orientation of the northwest has turned definitely toward Buenos Aires. In the late 1850s one of the Argentina's first railroads was built from Rosario to Córdoba and Tucumán. Almost at once the stagnant economy began to show new signs of life. In the 1860s sugar cane plantations were laid out south of the city of Tucumán along the eastern base of the mountains. This is the southernmost area in Argentina where absence of killing frost makes cane cultivation possible. Railroad development led to a rapid increase of the cane area, which spread out eastward until it was stopped by the winter frosts. Although this area receives enough rain to permit agriculture without irrigation, water actually is used to moisten the cane fields during the dry winters. As the railroad was built northward to Jujuy, sugar cane plantations extended in that direction. The chief crops from Tucumán northward are sugar cane and corn (maize).

South of Tucumán, where the whole piedmont is very dry, agriculture and settlement are dependent on water and all limited to places where rivers descend from the mountains into the eastern plains. The oases are proportional in size to the volume of water available. The largest ones are Mendoza, San Juan and San Rafael, but there are several smaller irrigated areas, such as La Rioja and Catamarca. In all these oases the crops include wine grapes and alfalfa. At San Rafael there is a considerable acreage of pear orchards.

Mendoza is important not only as an agricultural and wine-processing centre but also as a pass city. Just to the west is the Uspallata pass, over which railroad and highway provide connection with Chile. Actually the traffic over these facilities is small, for the two countries exchange little with each other.

In the high Andes are a few small mining communities. Argentina mines asbestos, beryllium, lead, zinc, copper, silver, tungsten, mica, fluorspar, asphalt and sulfur. Near Mendoza are some beds of low-grade lignite; and along the Andean front in Mendoza and also in Salta and Jujuy oil wells are in production.

2. Chaco.—The Chaco includes the northern part of Santa Fe, Santiago del Estero, the eastern part of Salta and the two provinces of Chaco and Formosa (*qq.v.*). It is an area that remains thinly populated excepting along its eastern and southern margins.

The oldest of the settlements on the margins of the Chaco are those that are strung along the courses of the Río Salado and the Río Dulce. Long before the arrival of the Spaniards the Indians had grown crops on the flood plains of these rivers. When the floods of the rainy season had receded, certain wet spots on the flood plains remained, and these could be planted with maize or other crops. The same method is still used. The wet spots, known as *bañados*, differ in arrangement each year because each flood results in a new pattern of gravel and sand. The Río Dulce, however, occupies a narrow channel upstream from Santiago del Estero, and there the pattern of *bañados* cannot shift from year to year. The chief commercial centre of this area owes its location to the stability of the channel.

The settlements along the eastern margin of the Chaco began as quebracho lumbering centres. The quebracho tree is cut and hauled to tannin-extracting plants located close to the Paraná. After the quebracho cutters had cleared the forest—in bands running northwestward into the interior of the Chaco—agricultural settlers came in and created small farms along the railroad lines. The chief areas of farm settlement run inland from Resistencia and Formosa, and the chief commercial crop is cotton. In the south, on the other hand, after the quebracho cutters had cleared the forest in Santa Fe state, the land was divided into large ranches and used for the pasture of cattle. These kinds of economic development are restricted by rainfall to the eastern half of the Chaco.

3. Mesopotamia.—Mesopotamia includes the part of Argentina that lies between the Uruguay river and the Paraná (hence the name). The region includes the provinces of Entre Ríos, Corrientes and Misiones (*qq.v.*).

Because of the difficulty of crossing the wide flood plain of the lower Paraná river, this part of Argentina has always suffered from isolation. It did not share in the moderate prosperity brought by the raising of mules on the southern shore of the Paraná. The region north of the Paraná is still connected with Buenos Aires only by ferry. The southern part of Mesopotamia has been developed for farming, and is today the major area of linseed production. The greater part of Mesopotamia, however, is used for pasture. It has become the leading area of wool production in Argentina. Some tobacco is grown around Corrientes in the northwest corner of the region. Where Misiones extends onto the Paraná plateau the Argentines have developed a string of yerba maté (Paraguay tea) plantations; this is the world's chief source of Paraguay tea, which is widely used in this part of South America.

4. Patagonia.—Patagonia (*q.v.*), the region south of the Río Colorado, includes four provinces: Neuquén, Río Negro, Chubut and Santa Cruz (*qq.v.*), and the federal territory of Tierra del Fuego (*q.v.*). This southern region makes up about 28% of the national territory, but it is occupied by only about 2.5% of the Argentine population.

The settlement of Patagonia by people of European origin oc-

curred late. Until the Indian campaigns of 1879–83, most of Patagonia was left to the native peoples, and the only settlements were at Punta Arenas (*q.v.*) in Chile on the Strait of Magellan and at Carmen de Patagones and Trelew in the northeast. As soon as the Indian menace had been eliminated, however, pioneer colonists began to move into Patagonia. The pioneer settlers included many Welsh, Scottish and English and also many Chileans from Punta Arenas and from Neuquén. The only agricultural area in Patagonia lies along the valleys of the Río Colorado and Río Negro, where summers are still warm enough to make the growing of grapes and pears profitable. South of the Río Negro the temperatures are too cool to support anything but alfalfa for animal feed. The traditional product of Patagonia is wool; the chief use of the land is for sheep grazing. During the winters the herds are sheltered in the canyons or in the lee of cliffs, but in spring they are driven to places where there has been enough winter snow to support a growth of grass. A major concentration of sheep is in the pre-Andean depression, especially in Chile north of Punta Arenas. The wool clip is brought by train or truck to the little ports and shipped by small vessels to Buenos Aires. Only in the north of Patagonia, in the Río Negro valley and around Neuquén and Bariloche, are cattle more important than sheep.

Patagonia is important, also, because of its oil. Oil was discovered in 1907 at Comodoro Rivadavia (*q.v.*) and this oil field has now become the largest source of oil in Argentina. In the 1940s a pipeline was built from Comodoro Rivadavia to Buenos Aires to supply that city with natural gas. Another kind of economic activity is the development of recreation facilities around Lake Nahuel Huapí. This beautiful lake on the Andean piedmont southwest of Neuquén has long been used as a summer route across the Andes to Chile. Many tourists stop at the lake to enjoy the scenery, fishing and other recreational attractions, and the area has been developed for skiing in winter.

5. Humid Pampas.—The concentration of people and wealth in the humid pampas and in the metropolitan area of Buenos Aires is the outstanding fact of Argentine geography. The humid pampas includes the whole of the province of Buenos Aires and parts of Santa Fe, Córdoba and La Pampa (*qq.v.*).

The humid pampas as a geographic region is a modern development, dating only from the last half of the 19th century. For the first three centuries of Spanish settlement the humid pampas was considered a poor region, good only for pasturage of range cattle and breeding of mules. The only permanent settlement of the humid pampas was along the northeast margin on the Paraná-Plata. Buenos Aires, Rosario and Santa Fe date back to the 16th century. Inland from these places the land was used for unfenced pastures on which the animals grazed on the native grasses. A little less than 100 mi. S. of the Paraná-Plata shore the surface of the humid pampas is marked by a chain of marshes, known in North American writings as the Salado slough. Spanish settlement did not penetrate to the south of these sloughs. A line of forts along the northern margin of the sloughs gave some protection for the settlers from Indian raids.

The occupation and development of the humid pampas beyond the Salado slough began only in the late 1870s. The first railroad in Argentina had been built out of Buenos Aires in 1857, and shortly thereafter the line from Rosario to Córdoba and Tucumán was constructed. Railroads were rapidly extended across the level plains during the decades between 1860 and 1880. The Indians were finally wiped out in a series of military campaigns between 1879 and 1883. By that time the potential productivity of the humid pampas had been vastly increased through a series of more or less related inventions. First was the railroad itself, which made possible the bulk transportation of goods of low value per unit of weight. Second was the steamship, which vastly reduced the cost of ocean shipping, and the refrigerator ship, which made it possible to ship meat across the equator. A fundamental invention was barbed wire, which in the 1870s suddenly made it possible to combine farming and grazing on the world's grasslands, where fencing had been impossible before. Other inventions include the windmill, well-drilling machinery, the steel plow, the harvesting combine and many others. In Argentina, when these new products were available, the land rapidly increased in value and, in accordance with Spanish tradition, it was quickly divided into vast private properties. The greater part of the humid pampas came into the hands of some 300 families, each family with an *estancia* measured in hundreds of thousands of acres.

Argentine landlords have always been chiefly interested in stock-

raising; their greatest prestige comes from owning a fine herd of purebred cattle, or fine horses or the best-quality sheep. But when the large British beef cattle were introduced to the humid pampas during the 1870s and 1880s, it was found that a feed crop had to be grown, for the native grasses were not adequate. Alfalfa proved to be ideally suited to this region, but to eliminate the native grasses and plant alfalfa it was found that the land had to be prepared by several years in wheat. To grow the wheat and plant the alfalfa, the landlords hired tenant farmers—mostly Italian, Spanish and other European immigrants—who grew the wheat for three or four years, then planted alfalfa and moved elsewhere. Alfalfa remains productive (four or five cuttings a year) for four or five years, after which another tenant is hired for the next cycle of wheat or corn or other grain.

Great Britain provided a constantly increasing market for both meat and grain. British capital, invested in railroads, grain elevators, packing plants, docks and shipping lines, provided the transportation facilities on which the whole prosperous system rested. As a result, Argentina became by far the leading commercial nation in Latin America.

The humid pampas was created as a geographic region in the process. Without the spread of wheat and cattle, the present outlines of the region could not have been determined. But wheat was grown as far toward the south and west as the rainfall made possible. With decreasing rainfall, yields of wheat and alfalfa declined. If the price of wheat or of cattle had been higher in the 19th century when this process of development was going on, the outline of the humid pampas would have been developed farther toward the dry areas. Once established and supported by railroad lines, the humid pampas appeared as a region distinctly different in agriculture from the semiarid lands farther west, which the Argentines know as the "dry pampas." The humid pampas itself has become differentiated into subregions. The eastern part, which is cool and poorly drained, is still used chiefly for animals grazing on grass—for sheep and cattle breeding. The cattle are fattened on alfalfa (not corn as in the United States), which is associated with wheat in a crescent extending from Bahía Blanca to Córdoba along the western boundary of the area. Around Rosario, where the rainfall is most dependable, corn is more important than wheat, but the corn is raised chiefly for export to be used as poultry feed in Europe. A zone of intensive dairy and truck farming has developed around Buenos Aires for the supply of the city population.

Buenos Aires began its modern development as a centre of manufacturing industry during World War I, and the development was intensified during World War II. During these wars, when the British chose to use their ships to carry meat rather than wheat, the wheat acreage was cut in Argentina and many tenants left the rural areas to seek employment in the cities. At these times new industries were built in Buenos Aires to process the products of the humid pampas and of the outlying regions of the country.

The humid pampas remains the lowest-cost producer of grain and meat in the world. The moist, mild winter climate, the level surface, the productive loess soil and the easy accessibility to a port combine to reduce the costs of sending food to the world markets. But the absence or scarcity of fuel and minerals makes Buenos Aires a high-cost producer of manufactured products.

(P. E. J.)

III. THE PEOPLE

1. Ethnic Groups.—The racial stock of Argentina is overwhelmingly white European, the Indian and Negro strain, so important in the composition of many Latin-American countries, being almost wholly absent. Although the mestizo (mixture of Indian and white) element is considerable in the provinces contiguous with Chile, Bolivia and Paraguay, and there are pure Indian communities in the northwest, the populated centres of Argentina, and in particular the metropolis of Buenos Aires, are almost pure white.

The formation of such an Argentine racial type is a comparatively recent development, occurring largely since 1870. Prior to that there was a considerable mestizo and even mulatto strain in the national composition. Although the region was never densely populated with Indians, there are thought to have been about 400,000 in the Río de la Plata at the start of the Spanish colonial period. Interbreeding with the Spanish conquerors resulted in the mestizo element, so characteristic of the early 19th century gaucho. Negro slaves brought to Buenos Aires in the 18th century added another mixture to the racial make-up. As the 19th century progressed certain alterations took place. The centre of population moved from the mestizo areas of the north and west toward the coast, where Spanish and newly arrived European elements formed the majority. A large portion of the pure Indian stock was eliminated in savage frontier warfare, while the mestizo and mulatto strains continued to grow fainter through intermarriage. The major racial change came as a result of the economic expansion of the pampas and the coast. The development of meat refrigeration and of the productivity of cereal grains on the pampas necessitated an enormous working force to raise cattle and, more important, to harvest the wheat and corn. The result was a flood of European immigration concentrated in the three decades following 1880 and amounting to a total addition of 3,500,000 from 1860 to 1940. Nearly three-fourths of these immigrants were Italian and Spanish, with Poles, Turks, French, Russian Jews and Germans contributing their share in that order. The centre of population came to be definitely located in the littoral and pampas regions and the composition of the population to be southern European.

2. Languages.—The language of Argentina is Spanish, although sharply distinguished from Castilian in pronunciation. The frontier and gaucho existence added new words to the language, and the influx of a large Italian element created many variations in accent and speech.

An underworld language called Lunfardo has developed in Buenos Aires composed of words from many languages, but principally Italian. This argot has been widely used in the words of Argentine popular songs, especially the tango. Large foreign settlements have maintained their languages both in the family and in private schools. French, German and English form large influential groups of the community, at least in Buenos Aires, and use of those languages follows the same order. Indian dialects still exist along the fringe of Argentina bordering Chile, Bolivia and Paraguay but contribute no significant addition to the national tongues (*see* SOUTH AMERICAN LANGUAGES).

3. Religion.—Approximately 95% of the Argentine population is Roman Catholic. The church is particularly strong in rural areas and in the older colonial centres such as Córdoba, Tucumán and Salta. Although the constitution requires that the president be a Catholic, and Roman Catholicism is supported as the official religion of the country, complete religious freedom was instituted as part of the 19th-century effort to attract European immigration. As in most Latin-American countries, women are the strength of the Catholic religion.

4. Culture.—A distinctive Argentine culture is hard to define since it has so many composite immigrant elements and is continually changing. The basic heritage is Spanish, and in many ways Spanish culture is the primary force in a national cultural pattern. The male is the dominant member of the family and of society, despite legislation under the Perón regime (1946–55) that gave women legal and political equality. Although industrialization and urbanization have weakened family bonds, loyalty and unity within a large family clan remain important social forces. The influence of the factory and the city has not completely destroyed the demand for a personal and sometimes almost paternal touch in business and politics and an extreme reliance on the leadership of the strong individual. The gaucho heritage of the country is largely relegated to story and poetry, and many Argentines rarely come closer to their frontier past than an occasional maté or *asado* (barbecue). Just as the recent population has been European in origin, its culture is mainly European. France is the cultural ideal of Argentina, and many aspects of art and culture follow French models.

The economic development of Argentina has created a large middle class, which in turn has fostered some individual cultural values. Though material gain and money values are dominant in

the minds of this class, as well as in those of the lower class, considerable respect is paid to artistic and intellectual values. A university education is sought after, and the average man has a marked interest in and knowledge of music, art and philosophy. Nationalism has not been diluted by the European origins, and the immigrant son has emphasized Argentine nationalism.

(Js. R. S.)

IV. HISTORY

1. Prehistory.—When the settlement of present-day Argentina by Europeans began shortly after 1500, all parts of it were inhabited by aboriginal Indians. How long they had been there, and how they got there in the first place, are questions about which scholars disagree. The best opinion seems to be that, like all other American Indians, they were sprung from Asian peoples who came to the new world perhaps 20,000 years ago by way of Bering strait and whose descendants gradually spread southward across both American continents and reached southernmost Argentina 5,000 to 8,000 years ago. It is also believed that not long after the beginning of the Christian era the aboriginal Americans who lived on the Pacific coast of South America somehow established transpacific contacts, received cultural influences from southeast Asia and perhaps Polynesia and passed these on to their neighbours in Argentina.

The total number of Indians living in Argentina about 1500 is estimated at 300,000, divided into many small tribes and speaking many different languages. Their various cultural levels covered a wide range, but none of them had developed a high civilization with large cities, great architectural monuments and accumulated wealth such as those that aroused the astonishment and cupidity of the Spaniards in the Aztec and Inca empires.

Compared with the latter, all the Indians of Argentina were relatively poor and backward. The most advanced of them lived in the northwest, under the cultural influence and, in part, the political control of the Inca empire. Many of them spoke the official Inca language, Quechua, and had acquired Inca skills in making pottery, working metals and farming with the aid of irrigation. At the other extreme, culturally as well as geographically, were the Indians of southernmost Argentina, whose primitive fishing and hunting culture had advanced little if any since their ancestors first settled the area.

Between these two extremes were most of the other Indians, who lived by hunting and by gathering roots and berries. Farming was confined largely to the lower slopes of the Andes and the borders of the Río de la Plata and its tributaries; it yielded barely enough for the Indians' subsistence, and this was a major cause of friction when the Spaniards arrived in the country and expected the Indians to feed them.

Most of the Argentine Indians were good and willing fighters, for intertribal warfare was common and prowess in battle rated high among the values of their culture. Their weapons were mainly of the Stone Age. But they were adaptable, as they proved by the rapidity with which they learned to excel in the use of the horses and firearms which were introduced into the country by the Spaniards. (*See* also INDIAN, LATIN-AMERICAN; SOUTH AMERICA: *Anthropology*.)

2. Discovery and Settlement.—Amerigo Vespucci (*q.v.*) is credited by some historians with the discovery of the Río de la Plata in 1501–02. Other historians deny this, but it is well established that Vespucci later stimulated the Spanish search for a southern strait which led to the discovery both of the Río de la Plata by Juan Díaz de Solís in 1516 and of the Strait of Magellan by Ferdinand Magellan in 1520. These two voyages revealed the main outlines of the Atlantic coast of what is now Argentina.

Sailing up the Plata, which he called the Mar Dulce, or Freshwater sea, Solís, with a small party, landed and was ambushed by Indians. Solís and most of his followers were killed; several disappeared. The survivors of the expedition returned to Spain.

The Río de la Plata was not explored again until Magellan arrived in 1520 and Sebastian Cabot in 1526. The latter picked up two survivors of the Solís expedition, who told glowing tales of the wealth of the region. Cabot discovered the Paraná and Paraguay rivers and established the fort of Sancti Spíritus (the first Spanish settlement in the Plata basin). He also gathered and sent home reports of the existence of a silver mountain and a rich people in the interior, together with some silver trinkets to support the story. Hence the main stream was renamed when Charles V created the Adelantazgo of the Río de la Plata (*plata*, "silver").

In 1528 Cabot met another expedition from Spain under Diego García (who had commanded a ship in the Solís expedition). Both Cabot and García had been supposed to sail for the Moluccas but altered their courses, influenced by excited tales about an "enchanted City of the Caesars," a variant of the Eldorado (*q.v.*) legend, which later incited many explorations and conquests in Argentina. As Cabot himself was preparing to search for the fabled city, a surprise attack by the Indians in Sept. 1529 wiped out his Sancti Spíritus base, and he and the survivors returned to Spain the following year.

Inspired by the conquest of Peru and the threat from Portugal's growing power in Brazil, Spain in 1535 sent an expedition under Pedro de Mendoza (equipped at his own expense) to settle and hold the country. Mendoza, a favourite of Charles V, belonged to one of the great families of Spain; his expedition was the largest sent to America up to this time (11 ships, 2,150 men, 100 horses). Ulrico Schmidel, the first historian of the region, accompanied the expedition. Mendoza was initially successful in founding Nuestra Señora Santa María del Buen Aire, or Buenos Aires (1536), but lack of an adequate food supply proved fatal. Bad treatment antagonized the primitive Indians of the neighbourhood, and they cut off supplies. Discouraged by Indian attacks and mortally ill, Mendoza sailed for Spain in 1537, dying on the way.

In the same year a party from Buenos Aires under Juan de Ayolas and Domingo Martínez de Irala, lieutenants of Mendoza, pushed a thousand miles up the Plata and Paraguay rivers. Ayolas was lost on an exploring expedition, but Irala founded Asunción among the Guaraní (*q.v.*), a sedentary, agricultural people. In 1541 the few remaining inhabitants of Buenos Aires abandoned it and moved to Asunción, which was the first permanent settlement in this area. In the next half-century Asunción played a major part in the conquest and settlement of northern Argentina.

Until the late 18th century the population of Argentina was heavily concentrated in this northern area, which was bounded on the south by a line running from Rosario, on the Paraná, through San Luis to Mendoza, on the eastern slopes of the Andes. Buenos Aires, re-established in 1580 by Juan de Garay with settlers from Asunción, was largely isolated from this area as well as the rest of the world, except for smuggling. As a result, as late as 1725 it had a population of only 2,200.

Northern Argentina as well as Buenos Aires was settled mainly by the overflow from neighbouring Spanish colonies, Chile, Peru and Paraguay (Asunción). There was little direct migration from Spain, probably because the area lacked the attractions of Mexico, Peru and other Spanish colonies, such as rich mines, a large supply of tractable Indian labour, accessibility and the privilege of direct trade with Spain.

The dependence of Argentina on neighbouring colonies for its first Spanish settlers is shown by the following summary: Santiago del Estero, the first permanent settlement by Europeans in Argentina, was founded in 1553 by an expedition from Chile under Francisco de Aguirre, other groups coming from Chile founded San Juan and Mendoza (both 1562) and San Luis (1596). From Paraguay came the founders of Corrientes and Paraná (both 1588), Santa Fe (1573) and the second Buenos Aires (1580), while Peruvians founded Tucumán (1565), Córdoba (1573), Salta (1582) and La Rioja (1591). These dozen communities, all established within 43 years after 1553, continued to be the main centres of Argentine life throughout the colonial period, and very few important additions were made to the list in the national period.

In these communities a simple but vigorous society developed on the basis of Indian labour and the horses, cattle and sheep imported by the Spaniards, as well as native products such as corn and potatoes. Some of the Indians worked as virtual serfs (not slaves) under the encomienda system, others in free villages

and others in missions established by the Roman Catholic Church, which played a notable role in the whole colonizing process. As few Spanish women accompanied the early settlers, there was much intermarriage with the Indians. Of the offspring (mestizos), some achieved high positions in society, but many became gauchos, or cowboys (see *The People*, above). On the fringe of the conquered zone, Indian warfare continued as late as 1883.

3. Colonial Development.—Politically, Argentina was a divided and subordinate part of the viceroyalty of Peru until 1776, but three of its cities—Tucumán, Córdoba and Buenos Aires—successively achieved a kind of leadership in the area and thereby sowed the seed of community feeling that much later grew into the idea of Argentine national union. Each of the three cities achieved leadership in a different way, and each way represents a distinct stage in the history of Argentina, though the three stages overlapped.

Tucumán came first. Its leadership lasted from the latter part of the 16th through the 17th century. Its political and ecclesiastical jurisdiction extended over most of northern Argentina, including Córdoba; the chief exceptions were San Juan and Mendoza, which depended upon Chile. Tucumán also dominated the chief economic activity of Argentina at that time, which consisted in supplying the rich silver-mining area of Upper Peru (Bolivia) with foodstuffs and livestock in return for European manufactures and other goods brought from Spain via Panamá and Lima, Peru.

Under the same economic system Córdoba rose to leadership in the 17th and 18th centuries because the expansion of settlement gave the city a central location and because the University of Córdoba, founded in 1613, put the city in the intellectual forefront in Argentina and Spanish America in general. Administered by the Jesuits until their expulsion from the Spanish empire in 1767, and best known for its theological studies, the university made Córdoba a symbol of conservatism.

On the other hand, Buenos Aires, which rose to leadership in the late 18th century, symbolized three important reorientations of Argentine life from west to east. The first, economic, was the shift from trade with the now declining silver mines of Peru to direct transatlantic trade with Europe. Another, intellectual, resulted from the rise of interest in the new ideas of the European Enlightenment, which found fertile soil in cosmopolitan Buenos Aires and challenged the old order represented by Córdoba. The third, political, was brought about by detaching Spain's possessions in the Plata basin (modern Argentina, Uruguay, Paraguay and southern Bolivia) from the viceroyalty of Peru and erecting them into the new viceroyalty of La Plata, with Buenos Aires as its capital (1776).

Spain created the new viceroyalty mainly for the purpose of putting its Plata dominions in a better defensive position. The chief threat came from Brazil, which was growing rapidly in population, wealth and military potential and whose metropolis, Portugal, was the traditional ally of Great Britain, the traditional enemy of Spain. Though the creation of the viceroyalty of La Plata thus was primarily a measure of imperial defense, it conferred important benefits on Buenos Aires. Besides making the city a viceregal capital, with all the prestige and profit attached to that status, it for the first time threw the port of Buenos Aires open to transatlantic trade with Spain and, through Spain, with other countries. This resulted in a great increase not only in the legal trade of Buenos Aires but also in its already flourishing smuggling trade with Brazilians, Frenchmen and Britons (the enemies of Spain were not necessarily the enemies of Buenos Aires).

The city continued its rapid growth (from a population of 2,200 in 1726 to 33,500 in 1778 and 45,000 in 1800). It also became cosmopolitan: in addition to foreign trade, merchants and books, its growing wealth and cultural sophistication in the later years of the century attracted French and Portuguese teachers of dancing and music, an Italian painter and a French musician who built for the cathedral an organ that lasted for nearly a century.

The growth of commercial Buenos Aires stimulated an increase in the number of gauchos. One of the main occupations of these half-wild cowboys, "centaurs of the pampa," who seldom if ever saw the city, was the killing of cattle for their hides and horns major items in the Buenos Aires export list. Accustomed to frontier fighting and, though hostile to discipline, easily led by a strong man, the gauchos provided much of the manpower for the succession of Argentine revolutions, civil wars and dictatorships that occurred between 1810 and 1880. In retrospect, they appear as an ambivalent factor in Argentine life. On the one hand, they represented the barbarism of the title of Domingo Faustino Sarmiento's (*q.v.*) book *Facundo*, or "The Conflict Between Civilization and Barbarism" (1845); on the other, they are also regarded as the embodiment of some of the most highly prized traits of the Argentine people, such as independence of spirit, courage, and pride in their country.

4. Independence.—In Argentina, as in most of Spanish America, the independence movement was precipitated mainly by Napoleon's intervention in Spain, beginning in 1808 (*see* SPAIN: *History*). The way had been prepared for it, however, by the deep-rooted antipathy between "peninsular" Spaniards and American-born creoles; by the examples of the American Revolution of 1776 and the French Revolution of 1789; and by ideas drawn from earlier Spanish sources as well as from Rousseau and other French and English writers of the Enlightenment. Other important factors in the case of Argentina were Great Britain's invasion of the viceroyalty of La Plata in 1806–07, the ignominious flight of the Spanish viceroy and the defeat and expulsion of the British army from Buenos Aires by the Argentine people. The result was to weaken ties with Spain and nourish a nascent Argentine patriotism; a poem written in celebration of this victory gave currency to the name Argentina.

The break began in 1808 when Napoleon's intervention plunged Spain into a civil war between two rival governments. One was set up by Napoleon, who forced the rightful king, Ferdinand VII, to abdicate, placed his own brother Joseph Bonaparte on the throne and supported him with a French army. The other was created by the union of a number of patriotic juntas in Spain under a regency, which governed in the name of the exiled Ferdinand VII and was aided by a British army under the duke of Wellington. Both governments claimed authority over all the Spanish empire; in most of Spanish America, however, while there was general sympathy with the regency, its claim as well as Joseph's was rejected, mainly on the ground that an interregnum existed and that under ancient principles of Spanish law the king's dominions in America had as much right as those in Spain to govern themselves pending the restoration of a lawful king.

In Argentina this view was sustained by the creoles rather than by the "peninsular" Spaniards, and it was given effect by the Buenos Aires *cabildo*, or municipal council. This ancient Spanish institution had existed in all the colonies since the 16th century. It was aristocratic and its powers were very limited, but it was the only organ that had given the colonists experience in self-government. In emergencies it was converted into an "open" *cabildo*, a kind of town meeting, by adding to the regular members all the men of substance in the community; even then it was not a fully democratic body, since the common people were not included.

On May 25, 1810, such an "open" *cabildo* in Buenos Aires set up an autonomous government to administer the viceroyalty of La Plata in the name of Ferdinand VII, pending his restoration. This was not a declaration of independence but, on the contrary a profession of loyalty to the king. The profession was probably sincere on the part of most of the *cabildo* members who made it, but when Ferdinand was restored in 1814 he promptly proved himself one of the worst kings Spain had ever had. Thereupon an assembly representing most of the country met at Tucumán and on July 9, 1816, declared the country independent under the name of the United Provinces of the Río de la Plata.

In the meantime the government at Buenos Aires had taken the lead in grappling with the problems facing the country. The main problems, and their development down to 1829, when the long dictatorship of Juan Manuel de Rosas (*q.v.*) began, may be summarized as follows:

a. Defense. At no time after May 25, 1810, was Buenos Aires directly threatened by the Spanish royalists, but it took several years of hard fighting to defeat them in northern Argentina and even after that they were a constant threat from their main base in Peru. This problem was solved by the flanking strategy of Argentina's great liberator, José de San Martín (*q.v.*). He first led his army in an epic march from Mendoza across the Andes to Chile, where he helped the local patriots win their independence (1817–18), and then, with the support of a fleet organized in Chile, sailed up the coast of Peru and began its liberation. He withdrew in 1822 in favour of the Venezuelan liberator Simón Bolívar (*q.v.*), who completed the task two years later.

b. Territorial integrity. The Buenos Aires government tried to maintain the integrity of the old viceroyalty of the Río de la Plata, but the outlying portions, never effectively controlled, soon were lost: Paraguay in 1814, Bolivia in 1825 and Uruguay in 1828. Even the remaining core, modern Argentina, frequently was disunited until 1860. The root cause of the trouble, the question of the relation of Buenos Aires to the rest of the country, was not settled until 1880, and even after that it continued to cause dissatisfaction, though never again to the point of disrupting the union.

c. Form of government. Until 1820 a small but influential group sought secretly to establish a monarchical government in Argentina, but in that year the exposure of their plan led to a revolution that defeated it—permanently, as it proved. Thenceforth there was general agreement that the government should be republican but violent disagreement as to whether it should be centralized or federal. This was literally a fighting question between the two groups, who were identified respectively as Unitarists and Federalists. Unitarian power reached its peak under Bernardino Rivadavia (*q.v.*), who was named president in 1826 but resigned the following year partly because of the unsatisfactory course of the war of 1825–27 with Brazil over Uruguay. After a chaotic interlude, a long period of Federalist domination began under the leadership of Rosas.

d. Extent of the revolution. The question was whether the revolution should stop with the winning of independence or be continued within the country with a view to reforming Argentine society. Rivadavia urged the latter; for example, he wished not only to liberalize the system of great landed estates inherited from the colonial period but also to bring about a cultural revolution by replacing the Spanish-Catholic traditional culture with a modern, secular and scientific culture borrowed from France, Great Britain and the United States. This reform program had the misfortune to become identified, through Rivadavia, with Unitarism and the luckless war with Brazil. When Rivadavia fell in 1827 the reform movement collapsed with him, and it was not revived until a quarter-century later.

5. Rosas Regime.—Rosas came to power partly as a representative of the conservative reaction against these reforms, partly as the *caudillo* (military leader) of the gauchos and the champion of "order and discipline," a motto that appealed strongly to many people in a country that had suffered much from disorder and violence most of the time since 1810. At first his power was confined to the province of Buenos Aires, of which he was elected governor in 1829, and other provinces had their own *caudillos.* By 1835, however, he had subordinated or eliminated his rivals, and from that time until his overthrow in 1852 he was master of Argentina.

Rosas' success was due to several factors in addition to the forces that had sustained him at the outset. One of the most important was the Mazorca, an organization founded in 1833, whose members included respectable citizens as well as the scum of society. The ways in which the Mazorca supported Rosas ranged from staging popular demonstrations in his honour to assassinating his opponents. Clergy and magistrates joined in the demonstrations, paraded Rosas' portrait through the streets as if in a religious procession, and sometimes even placed it on church altars. Another major factor was the strong appeal that Rosas made to Argentine patriotism by his defense of national interests against all comers, including the greatest powers: against Great Britain in the controversy over the Falkland Islands (*q.v.*), which Argentina claimed but which Britain seized at this time and never gave up, and against both Britain and France during their armed interventions in the Plata between 1838 and 1850.

On the other hand, Rosas' regime suffered from defects that ultimately proved his undoing. He carried nationalism to the point of a xenophobia that excluded not only the foreign cultural influences that Rivadavia had wished to promote but also foreign immigration, enterprise and capital. As a result, the late colonial economic system continued with little change. This pleased lovers of the *status quo,* but not forward-looking Argentines interested in the country's economic development. Partly on this ground, but still more in defense of freedom, many of the intellectual elite turned against Rosas. Among them were Juan Bautista Alberdi, Bartolomé Mitre (*qq.v.*) and Domingo Faustino Sarmiento, who later were to lead in remaking Argentina. Forced to flee Rosas' tyranny, they kept up a vigorous literary barrage against him from Chile, across the Andes, and Montevideo, across the Plata. Their journalistic attacks did not bring about his overthrow, but they prepared the way for it by weakening his moral authority.

What overthrew Rosas was the combination of a revolt in his own army with intervention from Brazil and Uruguay, and in both cases Rosas himself was largely to blame. Once a vigorous field officer, he left it to others, chiefly Gen. Justo José de Urquiza (*q.v.*), to put down the revolts that plagued the last decade of his regime. He also made the mistake of favouring the commerce of Buenos Aires at the expense of Urquiza's part of the country, the provinces of Entre Ríos and Corrientes, in Mesopotamia. Finally, Rosas incensed the Brazilian government and many of the Uruguayan people by his political and military intervention in Uruguay; this was dramatized by his long siege of Montevideo ("the second siege of Troy" in local histories), where Argentine exiles were writing and conspiring against him.

On May 1, 1851, Urquiza proclaimed his revolt against a "despot" who had violated a long-standing promise to establish constitutional government in Argentina. Four weeks later Urquiza formed an alliance with Brazil and Uruguay. The allies first forced Rosas' troops to raise the siege of Montevideo and then defeated his main army in the short but decisive battle of Caseros (Feb. 3, 1852). Rosas fled with his son and daughter in an English ship and never returned. He died at Southampton, Eng., a quarter-century later.

6. National Consolidation.—Needing to justify his rebellion against Rosas, Urquiza called a constitutional convention, which met at Santa Fe in 1852. Jealous and suspicious Buenos Aires abstained, but the convention adopted a constitution for the whole country. This was proclaimed in effect on May 25, 1853, the anniversary of the famous *cabildo* of 1810.

In an effort to reconcile Unitarists and Federalists, the framers of the constitution of 1853 made it a compromise between the two extremes. It was modeled mainly on the constitution of the United States, though with some important modifications, most of them proposed by Alberdi in a book written for the occasion, *Bases and Starting Points for the Political Organization of the Argentine Republic.* Two major differences related to the presidency and religion. The president of Argentina was not permitted to succeed himself, but he was given a six-year term and even more extensive powers than the president of the United States. In religion, the constitution of 1853 set up a system somewhat like that of England with its established Anglican Church, for the Argentine government was required to support the Roman Catholic Church; but religious freedom for other faiths was stipulated, and, in the sequel, enforced.

The province of Buenos Aires refused to join the new union, whose first elected president was Urquiza and whose first capital was Paraná. Serious friction soon developed. One source of it, as under Rosas, was a conflict of economic interest, which Urquiza now sharpened by trying to build up the port of Rosario as a rival to Buenos Aires. Related causes of friction were the questions whether, if the province of Buenos Aires came into the union, its capital, the city of Buenos Aires, should be made the

national capital, and what disposition should be made of its customs revenues.

Urquiza decided to impose union by force. Led by Mitre, Buenos Aires accordingly went to war in 1859, was defeated and in 1860 joined the union, though only after the adoption of a number of constitutional amendments proposed by the recalcitrant province was assured. One of these relaxed tension over the Buenos Aires question by providing that the location of the national capital should be determined by congress at a later date. Another amendment legalized all the successive names, each with its own political connotation, under which the country had gone since the beginning of independence—United Provinces of the Río de la Plata, Argentine Republic and Argentine Confederation—but stipulated that all laws should be adopted in the name of the Argentine Nation.

The terms of settlement were unacceptable to many, and new rancors were added soon after Urquiza was succeeded in the presidency in 1860 by Santiago Derqui, an ambiguous figure who had no strong support in either camp. Another civil war broke out; this time Buenos Aires won, defeating the federal forces led by Urquiza at the battle of Pavón (1861). Derqui resigned and Mitre was elected president in 1862. Buenos Aires became the seat of government.

Despite the continuance of domestic turmoil and a costly war with Paraguay, notable progress in carrying out the liberal program of economic and cultural development was made during the presidencies of Mitre (1862–68) and his next two successors, Sarmiento (1868–74) and Nicolás Avellaneda (1874–80). With the aid of foreign capital and technology, railroads were built; alfalfa, barbed wire, better breeds of cattle and sheep, and the refrigeration of meat were introduced. The country became a large-scale exporter of pastoral products to Europe. As commerce grew, so did the revenues of the government, which used them to foster the rising tide of immigration and to lay the foundations of the best system of public education in Latin America, first under Mitre but principally under Sarmiento, well named the "schoolteacher president." Both enlisted the aid of foreign scholars and scientists. Also during this period two newspapers were established that won and still enjoy high esteem for their quality: *La Prensa*, founded in 1869 by Ezequiel Paz; and *La Nación*, founded in 1870 by Mitre, who edited it for many years.

Sarmiento greatly admired the United States, which he had visited twice (first in 1845 and later as Argentine minister, in 1865–68), and even urged Argentina to "North Americanize" itself. The two outstanding developments in the country's foreign relations during this period, however, took place in Mitre's administration. First, on the occasion of a conference of Spanish American states at Lima in 1864–65, Mitre made a classic statement affirming his country's traditional opposition to multilateral security arrangements. The flexibility of this rule was shown by the second outstanding development· his commitment of Argentina, in alliance with Uruguay and Brazil, to the war of 1865–70 with the dictator of neighbouring Paraguay. The allies had great difficulty in winning, and as late as the 1960s Argentina had never fought another foreign war.

Avellaneda's administration was distinguished by two domestic events occurring near its close, the combined effect of which was a powerful stimulus to the further development of Argentina. In 1879 Gen. Julio A. Roca, "the last of the conquistadors," brought the long cycle of Indian wars to a close with a victory that opened the rich wide-spreading pampas to settlement. In 1880, following another revolt by Buenos Aires and its suppression, the perennial question of the city's status was definitively settled by its federalization. Its new status was much the same as that of the District of Columbia, with the important exception that its citizens have always been permitted to vote in national elections. This solution ushered in a long period of relative peace and order, which increased the attractiveness of Argentina to foreign capital and business enterprise. They found golden opportunities in the newly opened pampas.

7. The Oligarchy, 1880–1916.—The hero of the Indian war of 1879, General Roca, was elected president in 1880. His administration marked the beginning of the domination of Argentina by a new oligarchy, which lasted a third of a century. This oligarchy contained many members of the old patrician class of great landowners. At its core were the big ranchers or *estancieros*, who possessed great social prestige as well as economic and political influence in this traditionally pastoral country. They functioned as a power group through the exclusive Argentine Rural society organized in 1866, which has been described as probably the most powerful farmers' organization in the western hemisphere. But the oligarchy also contained men who had made their fortunes in other ways as well. and it was oriented toward the foreign commerce, capital and enterprise, mainly British, to which it largely owed its prosperity. Its members were not entirely united, however, as the revolution of 1890 showed.

Keeping control of the government through fraud and force, the oligarchy enriched itself in a way reminiscent of the "gilded age" of the Grant administration in the United States. The tide of immigration continued to mount, and an abundant supply of cheap labour aided in bringing about a great expansion of cereal production; wheat was first regularly exported from Argentina in the 1880s. By 1900, agricultural products had already caught up with pastoral products in value of exports.

An outstanding feature of Argentine political life in this decade was an anticlerical campaign launched under the influence of European liberal and positivist thought. The most spectacular results were the passage of laws secularizing public instruction and providing for civil marriages and burials, the expulsion of the papal nuncio, and a breach in relations with the Vatican that lasted from 1884 to 1900.

Miguel Juárez Celman, Roca's brother-in-law, who had led the anticlerical movement, was elected president in 1886, but mounting Catholic resentment contributed to a revolution that unseated him, though not his government. Other factors in bringing it about were the general disgust with the corruption of the regime which was shared by many of the military, headed by Gen. Manuel J. Campos; an economic recession; and unrest among the growing proletariat led by Leandro N. Alem and the recently organized labour unions. The various groups of malcontents joined together in an organization called the Civic union, whose heterogeneous elements soon fell apart, but not before it had played a major part in precipitating a revolt in July 1890. The revolt won a sweeping success in the first two days, and then was as quickly put down; some attribute the reversal to desertion of the rebel cause by its military leaders in protest against the growing power of its left-wing civilian element headed by Alem.

As a concession to the critics of the regime, Juárez Celman was forced to resign, but this made no substantial change in its nature. Vice-President Carlos Pellegrini, who, with General Roca had mobilized the government forces against the revolt, succeeded to the presidency, and he and his successors maintained the oligarchy in power for more than two decades. The government was bankrupt when Pellegrini took over, but he restored its solvency on a sound basis by a series of far-reaching measures that caused him to be compared with Alexander Hamilton.

Economic difficulties in the 1890s and the resultant political discontent produced two new parties of protest, both of which played important roles in Argentine public life thereafter and both of which derived strength from the "new Argentines," the Spanish and Italian immigrants who had poured into the country in the past generation. The stronger of the two was the Radical Civic union, often called simply the Radical party, which split off from the Civic union in 1892. It was headed first by Alem and then, after his death in 1896, by his nephew, Hipólito Irigoyen who ruled it until 1930. By way of protest against the oligarchy's system of force and fraud, the Radicals adopted a double policy of "absention" (boycotting elections) and revolution.

The Socialist party, the second of the two, was organized in 1895 by Juan B. Justo. In contrast to the Radicals, who claimed to speak for all right-thinking Argentines, of whatever class or condition, the Socialist party aspired to represent only a single class, the workers. Perhaps because its doctrinal roots were not Argentine, it never gained mass support even in its stronghold.

Buenos Aires, where its hold on labour was shared by Radicals, anarchists and other groups.

In 1898 Roca was elected for a second term, marked by three notable developments in foreign policy: in 1900, the resumption of diplomatic relations with the Vatican; in 1902, the settlement of a dangerous boundary controversy with Chile, and in the same year the pronouncement of the Drago doctrine (*q.v.*) which, like the earlier Calvo doctrine, was an Argentine protest against intervention.

Roca's second administration coincided with a renewal of economic expansion and prosperity in Argentina, but political unrest continued to grow. By 1906 it had assumed such alarming proportions that Pellegrini, in his last speech, warned his fellow oligarchs of the danger of civil war if they did not "open the flood-gates" to democracy by permitting free and honest elections. They were opened in 1912 when a conservative president, Roque Sáenz Peña, forced his reluctant party in congress to pass the electoral reform law that bears his name. It established secret and compulsory voting (for males) and the system of the "incomplete list"—a system designed to assure minority representation—and provided for a new registration of voters. By these simple provisions the Sáenz Peña law opened a new period in the political history of Argentina. In the next national election, 1916, the oligarchy was at last turned out and the Radicals came to power, with Hipólito Irigoyen (*q.v.*) as president.

Despite the political turmoil, a number of talented writers appeared at this time. Headed by Ricardo Rojas, they expressed in various ways the new nationalism stimulated by the centennial celebration of independence in 1910. This was a generation that looked back as well as forward; it was at this time that the 40-year-old gaucho poem *Martín Fierro* gained recognition as a national epic, though the gauchos themselves had disappeared before the march of progress.

8. Radical Regime, 1916–30.—As World War I was in progress when Irigoyen took office, foreign affairs had first claim on his attention. The preceding conservative administration had committed Argentina to a policy of neutrality, and Irigoyen adhered to it even after the United States' entry into the war in 1917, as did several other Latin-American governments. He also sought to strengthen his position by convoking a conference of Latin-American neutrals (which never met). As a result, he was charged with pro-Germanism, but proof of the charge is lacking. Rather, his course seems to have been determined by the traditional nationalism of Argentina and his own anti-imperialism, the latter strongest against Great Britain, though the United States shared his disfavour.

Irigoyen added substantially but not spectacularly to the small volume of social legislation built up since it was initiated by the Socialist Alfredo Palacios in 1902. Organized labour was the principal beneficiary, but Irigoyen's sympathy for labour had definite limits, as he showed by his suppression of a dockworkers' strike at Buenos Aires in 1919. A reform and extension of the university system was begun the same year.

Irigoyen made liberal use of the practice of federal intervention in the provinces, a practice that already had gone far toward converting Argentina from a federal union into a centralized national state. Such interventions enabled him to control provincial elections and thus to strengthen his position in his own party as well as in the federal government. His measures alienated some of the best elements in his own party, but by such tactics as opening the executive offices in the Casa Rosada to all comers, he convinced the masses that he was their champion.

Unable to succeed himself, in 1922 he passed the presidency on to his fellow Radical, Marcelo T. de Alvear, a member of one of the country's old patrician families. Alvear's administration is notable chiefly for the culmination of party tensions in a schism between its conservative wing, the Antipersonalists, led by Alvear, and the rest of the Radical party, which remained under the control of Irigoyen. This administration also was marked by the beginning of a long controversy with the United States over the latter's exclusion of Argentine beef through a sanitary regulation (1927) aimed against foot-and-mouth disease.

BURTON HOLMES FROM EWING GALLOWAY

"CHRIST OF THE ANDES," A STATUE ERECTED ON THE BORDER BETWEEN ARGENTINA AND CHILE IN 1902 TO COMMEMORATE THE PEACEFUL SETTLEMENT OF A BORDER DISPUTE BETWEEN THE TWO NATIONS

Irigoyen was re-elected president in 1928 by a margin of two to one in the popular vote (800,000 to 400,000), although he did not announce his candidacy until the eve of the election. This was a great personal triumph but, since it was interpreted by friends and enemies alike as giving him carte blanche, it contributed to his undoing and that of his party, of which he was now the master. On the one hand, it aroused among his followers expectations that he failed utterly to fulfill. They expected him to move forward rapidly with projects of social reform and nationalization that Alvear had been blamed for neglecting. Instead, Irigoyen concentrated his attention on political maneuvers, such as his interventions in San Juan and Mendoza, which were carried out in a way that shocked all but blindly loyal Radicals. On the other hand, important elements among the opposition became alarmed lest Irigoyen use his carte blanche to make himself a dictator and cripple the opposition permanently. Such fears were felt by some who were good democrats and also by the increasing number of those who were antidemocratic but who still would not tolerate a Radical dictatorship.

This increase of antidemocratic sentiment was one of the major features of Argentine history in the 1920s. It was due partly to contagion from abroad—mainly the Italy of Mussolini and the Spain of Primo de Rivera, and to a less extent from the Catholic right in France and Communist headquarters in Moscow. It was also due to the revival of Argentina's own Rosas tradition and to the spread of a new doctrine among some of the military—the doctrine that it was their mission to regenerate a nation debased by generations of inept and corrupt civilian government.

The crisis was hastened by the world-wide economic depression that began in 1929. Deriving nearly one-third of its gross national product from an export trade consisting mainly of agricultural and pastoral products, Argentina was one of the first countries to suffer severely. Action was urgently called for, but it was not forthcoming from Irigoyen. Now an old man, he had never been a good executive, knew little about economics and finance and

was too jealous of his own power and suspicious even of his own lieutenants to let anyone act for him. The government was paralyzed while the country drifted to ruin.

9. Conservative Restoration.—On Sept. 4, 1930, a part of the army, led by Gen. José F. Uriburu (*q.v.*), removed Irigoyen and took over the government in an almost bloodless revolution and amidst a popular acclaim in which almost everyone except the more resolute Radicals joined. As a young subaltern Uriburu had taken part in the abortive revolt of 1890; blaming that failure on the civilians, he kept firm control of this revolt and of the provisional government that followed it, which was military. He had been converted to fascist ideas and planned to establish a corporative state governed by the elite, but this plan naturally had no popular appeal and a large part of the army, led by Gen. Agustín P. Justo, an Antipersonalist and former minister of war under Alvear, refused to go along with him. The Radical party soon re-formed, the pressure on Uriburu became irresistible, and late in 1931 he permitted the holding of an election to restore normal constitutional government.

General Justo was nominated by a combination of Conservatives and Antipersonalists. The Radicals made a serious mistake by nominating Alvear, who had just rejoined them. Uriburu declared Alvear constitutionally ineligible on the good ground that less than a full term had passed since the end of his previous term in 1928; but the Radicals refused to nominate anyone else, and most of them abstained from voting, though some voted for a candidate who did not have a chance. Justo was elected by a large majority.

Shortly after Justo took office early in 1932, a formal alliance or *Concordancia* was established by the Conservatives and the Antipersonalists, who controlled Argentina until the military again took over in 1943. Since the Antipersonalists, like their allies, occupied a position to the right of centre, this may be called the period of conservative restoration. It resembled the pre-Irigoyen regime in some important respects. There was again a pro-British oligarchy controlled by and governing for the great landowners who sold their products abroad, mainly in Great Britain. A typical measure was the Roca-Runciman agreement of 1933, which assured British purchases of Argentine beef in return for preferential treatment of British goods imported into Argentina. On the fringe of the oligarchy a new industrial interest had developed since 1914, but government policy still favoured the cattle interests.

The early years of Justo's administration were marked by constructive measures, such as those by which his minister of finance, the former Socialist Federico Pinedo, promoted recovery from the depression and, in his own words, "completed the economic unification of Argentina," but the regime soon slipped back into the practices of the Roca and Juárez Celman period. The election of 1937, by which the *Concordancia* kept itself in power, was as scandalous as any in the country's history. The new president, Roberto M. Ortiz, deplored these practices and sought to correct them, but ill-health forced him to resign, and they were renewed under his successor, Ramón S. Castillo, who was believed to be planning to dictate his own successor when the military revolt of 1943 drove him from office. Finally, the *Concordancia* showed little or no interest in the welfare of the masses. The Roosevelt New Deal of the 1930s had no counterpart in the Argentina of the *Concordancia*.

In foreign affairs, the record of the conservative restoration was checkered, but one constant factor in it was a certain antagonism toward the Pan-American system and its chief sponsor, the United States, which was making a determined effort to strengthen the system. At all times this antagonism reflected resentment of the implicit challenge of the United States to the leadership of Latin America to which Argentina aspired; but it was due also to other factors, which changed greatly from Justo's administration at the beginning to Castillo's at the end. Under Justo and his talented minister of foreign affairs, Carlos Saavedra Lamas, foreign policy was oriented mainly toward Great Britain and the League of Nations; the universality of the latter was greatly preferred to Pan-American regionalism. By Castillo's time, however, World War II had broken out, the League of Nations had virtually disappeared, Great Britain was fighting for its life, and a German victory seemed almost certain. Consequently, Castillo's policy was dominated by a determination to remain neutral and to protect Argentina's position by keeping on good terms with Germany. The antagonism generated by this policy was accentuated by the United States entry into the war.

10. Perón Regime.—On June 4, 1943, Castillo was overthrown by the Grupo de Oficiales Unidos (G.O.U.), composed of high-ranking officers of the German-trained army, among them Castillo's own minister of war, Gen. Pedro P. Ramírez. A provisional military dictatorship was established that in 1945–46 evolved into a pseudoconstitutional regime headed by one of its members, Col. (later Gen.) Juan Perón (*q.v.*).

The G.O.U. had many grievances, such as that Castillo was letting Argentina fall behind its traditional rival, Brazil, in military strength, and that the political parties had proved themselves unfit to govern the country. The parties had indeed failed to respond to the challenge of recent years and had lost the respect of the public at large. The democratic labour unions, too, were divided and demoralized, and Communism was making rapid headway among the workers.

In short, the G.O.U. moved into a power vacuum. It did so with the same sense of the army's mission to regenerate the nation that had inspired General Uriburu's coup of 1930, in which Perón had taken part, but in their conception of its mission its members differed widely, ranging from democratic to dictatorial and totalitarian, from anticlerical to ultra-Catholic and from pro-Ally to pro-Axis. There were also personal rivalries. As a result, an internal struggle for power broke out at once and continued until Perón finally won out in 1945 with the backing of the "colonels' clique" of younger officers and his mass following of *descamisados* ("shirtless ones"), which he won by demagogic appeals and wage increases and regimented in a greatly expanded Confederación General del Trabajo (C.G.T.).

At the end of World War II a strong reaction developed against Perón from many quarters, including the army, and early in Oct. 1945 he was forced to resign all his offices (vice-president, minister of war and secretary of the labour department); but a few days later a well-organized mass demonstration overawed his enemies and brought him back to power on Oct. 17. Perón did not resume any of his public offices, but he became candidate for the presidency in the election already announced but postponed and finally held in Feb. 1946. Perón won by a substantial majority and his followers (not yet organized in a single party) gained control of both houses of congress by wide margins. His opponents claimed that he had won through force and fraud, but the evidence does not support the charge.

On the eve of the election the United States department of state published a so-called Blue Book on Argentina. Containing documentary proof of Perón's Axis ties, the Blue Book apparently was expected to hurt his chances, but it appears rather to have helped him by bringing him votes that were in effect protests against this act of "Yankee intervention."

During his first term (1946–52) Perón in the main developed his regime along lines already indicated during his rise to power. He continued to base it on the army and labour; followed a policy characterized by economic and political nationalism and social reforms ostensibly aimed at a redistribution of wealth in favour of the masses; and suppressed the opposition.

Perón's most unconstitutional acts were draped with a mantle of legality, and he claimed to be giving Argentina "genuine democracy" in place of the "plutodemocracy" under which it had hitherto been exploited by what he called an "unholy alliance" between its own traitorous oligarchy and foreign capitalist-imperialism, an allusion mainly to Great Britain and the United States. The relations of the regime with the Roman Catholic Church, apparently friendly at first, had cooled by 1952, but this change was more apparent than real, for there was in fact no close alliance at the start and there had still been no open break by 1952.

Some new terms were invented and there were many new developments in detail. The terms included "justicialism" for Perón's domestic policy and "third position" for his foreign policy, the latter signifying, it was said, not neutralism but a middle way

between communism and capitalism. Also, on July 9, 1947, on the anniversary of Argentina's declaration of political independence in 1816, and at the same place, Tucumán, he issued a formal "Declaration of Economic Independence." His execution of the policies implied, however, was highly opportunistic and far less challenging to most vested interests, both foreign and domestic, than Fidel Castro's execution of similar policies was to be in Cuba in the 1960s. Though Perón asserted the right of expropriation, he made very limited use of it, preferring to purchase. In the leading case, that of the British-owned railways, comprising 70% of the total network in Argentina and bought in 1947, the price he paid, £150,000,000 ($600,000,000), was regarded by experts as generous. Similarly, he expropriated very few of the great estates that dominate the Argentine rural scene, but in this case neither did he purchase; he left the land problem largely untouched.

Perón applied more vigorously the doctrine that "the state may intervene in the economy and monopolize any given activity to safeguard the general interest" (constitution of 1949, article xxxviii). Even in this, however, he left a way open to private capital and private enterprise; all the mining and metallurgical industries, for example, were by 1950 in the hands of "mixed companies" combining private with government capital. The most thoroughgoing application of the doctrine was made in the case of the Argentine Trade Promotion institute, known as I.A.P.I. (Instituto Argentino de Promoción del Intercambio), which was given the right to purchase all Argentina's major crops at its own price and resell them abroad. Abusing these powers, I.A.P.I. forced Argentine farmers to accept ruinously low prices and used its handsome profits during the postwar boom period either to support the industrialization program or for graft. By 1952 Perón's policy of rapid industrialization at the expense of agriculture, combined with droughts and other misfortunes, had crippled the country's economy.

In 1949, mainly in preparation for the next election, Perón had a duly elected convention amend the constitution of 1853 so as to permit his re-election. Other amendments, too, were adopted, including one that made it easier for him to complete the purge of the federal courts which he had begun in 1947 by impeaching the unco-operative justices of the supreme court.

In 1951, women voted for the first time in an Argentine national election. Of the 7,500,000 votes cast, two-thirds went to Perón's ticket, which had the support of the Peronista party and the separate Peronista Women's party, founded in 1947 and 1950, respectively. The Radical candidates, Ricardo Balbín for president and Arturo Frondizi for vice-president, polled nearly 2,500,000 votes, a remarkable achievement in view of the fact that the Radicals were forced to campaign under constant harassment.

Perón began his second administration in June 1952 in the midst of a severe depression. The death of his wife the following month deprived him of his best liaison with the *descamisados* and his best adviser on political strategy. He now reversed some of his major policies and committed important political blunders. The first reversal came in 1953 when he abruptly abandoned his policy of handing out successive wage increases to the *descamisados* and shifted to a policy of *rapprochement* with Argentine business, foreign capital and the United States government. Late in 1954 he began an attack on the Catholic Church which he pressed through the first six months of 1955. In May of the latter year he gave great offense to Argentine national pride by signing an agreement with the Standard Oil Company of California for exploitation of the petroleum resources of a large part of Argentina. Then, after putting down a revolt in the air force in June, Perón threw himself back on the *descamisados*, inciting them to violence in support of his regime.

11. Radical Restoration.—On Sept. 16, 1955, the armed forces started a "Liberating" revolution at various points in the provinces under the leadership of Gen. Eduardo Lonardi at Córdoba. Perón's support crumbled so quickly that on Sept. 19 he resigned and took refuge on a Paraguayan gunboat, subsequently leaving the country. Until the restoration of constitutional government in 1958, the country was governed by a military junta representing the three services and headed by a provisional president—General Lonardi until Nov. 1955, and Gen. Pedro E. Aramburu thereafter. Throughout, Adm. Isaac Rojas was vice-president. This was a military dictatorship, but it was aimed at the restoration of constitutional government and in the meanwhile governed with the aid of advice from a civilian consultative council.

Argentina was politically divided and in serious economic difficulties. Peronism was still strong, especially among the workers, and the anti-Perón coalition dissolved with the fall of his regime. The pre-Perón Radical split occurred again; Balbín now headed the People's Radical party, Frondizi the Intransigent Radical party. Opposition to Lonardi on two issues forced him out within eight weeks: he was judged too conciliatory toward the Peronistas (his motto was the traditional Argentine phrase "neither victors nor vanquished") and too responsive to ultra-Catholic influence. The reversal of both policies by Aramburu did not bring tranquility. A plan for economic recovery and development, based on austerity, was prepared by a special adviser, Raúl Prebisch, chairman of the United Nations Economic Commission for Latin America, but concessions had to be made to insistent calls for wage increases, and nationalist feeling was opposed to terms that would attract foreign capital and enterprise.

Despite these and other difficulties, Aramburu ultimately effected the transition to constitutional government. In Aug. 1957 an elected convention failed in its major task of amending the constitution, but ratified an earlier decree by the provisional government re-establishing the constitution of 1853. Then, in Feb. 1958, national government elections were held. The Intransigent Radical party, headed by Frondizi, won both the presidency and overwhelming majorities in both houses of congress.

Frondizi was duly inaugurated on May 1, 1958. During the early part of his administration he made concessions, as expected, to Peronistas and Communists and to demands for a wage increase; took an unexpectedly hospitable attitude toward foreign investors; carried on the provisional government's policy of developing trade with "iron curtain" countries; and reaffirmed the Intransigent Radical principles of devotion to peace and democracy.

After Frondizi's inauguration Argentina returned to the practice of constitutional democracy, but it knew no peace at home. The country continued to live in an atmosphere of permanent political crisis. The roots of the trouble lay in social tensions antedating the Perón regime and in the mass aspirations and fervent nationalism encouraged by Perón and communicated even to anti-Peronistas. The immediate cause of conflict, however, was the economic program of stabilization—with its accompanying austerity—adopted by Frondizi in Dec. 1958 under the auspices of the International Monetary fund and with support from the United States. Reversing his former position, he even permitted foreign oil companies to exploit the petroleum resources of Argentina (see *The Economy*, below), thus alienating the Peronistas, Communists and nationalists who had supported him in 1958, and yet not appeasing his enemies among the Popular Radicals. In the congressional election of March 1960 Frondizi's party suffered a crushing defeat, though his own term still had four years to run.

Several times, both before and after the election of March 1960, revolution threatened, sometimes from the left wing through strikes and riots, sometimes from the right in the form of a *coup d'état* by extremists among the military. Frondizi's situation became paradoxical. Elected by an overwhelming majority, he became a "minority" president; formerly an extreme left winger and champion of civilian supremacy, he had come to steer a middle course that he could hold only with military help. He lost that support in March 1962 when he was removed from office in a *coup*, led by Gen. Raúl A. Poggi and other military officers, and placed under arrest. The action followed the elections of March 18, in which the Peronistas, permitted on the ballot for the first time since 1955, won substantial victories. On March 30 José María Guido, former head of the senate, was sworn in as president.

Guido's 18-month administration, though nominally civilian and constitutional, was in fact dominated by the armed forces. The latter, however, were divided among themselves, mainly over the issue of how to treat the Peronistas, who made up about one-third of the adult population and controlled most of the labour

organizations. Both of the main military factions, called Reds and Blues, were anti-Peronista, but the Reds demanded harsh treatment, even to the point of outlawing Peronism and maintaining outright military dictatorship for several years, whereas the Blues advocated less draconian measures and an early return to constitutional normality. The Blues ultimately prevailed, partly because moderation was counseled by the fact that the Peronistas and other labour groups were weakened by their own internal divisions and partly because most other Argentines were weary of the protracted domestic strife and wanted to begin rejuvenating the country's arrested economy.

Accordingly, an orderly national election was held in July 1963. Unexpectedly, it resulted in a victory for the presidential candidate of the People's Radicals, Arturo Illia, a 63-year-old physician and party worker from the province of Córdoba, who was inaugurated on Oct. 12. But, though Illia won the election, his vote was far short of a majority and he won in the electoral college only with support of several minor parties. His party likewise failed to gain control of congress. This situation, together with the sharp reverses suffered by the Peronistas and by Frondizi in this election, reinforced the party's tendency to moderation in domestic affairs. In foreign affairs, on the other hand, Illia took a strong nationalist line, and one of his first acts was to cancel Frondizi's petroleum contracts with foreign (mainly U.S.) companies. The applause with which most Argentines greeted this measure was one of several signs of an approach to the restoration of a national consensus for the first time in many years. On the other hand, radicals of both the right and the left continued to agitate, and in the mid-1960s the country still faced a formidable array of problems, such as large-scale unemployment, budget and trade deficits, and inflation. (A. P. WH.)

Local elections held during the early part of 1966 demonstrated that Peronism was still a strong force in the nation's politics. Alarmed at the prospect of a Peronist triumph in the elections for half the chamber of deputies scheduled for 1967, the military staged a bloodless coup in June 1966 and deposed Illía. Lieut. Gen. Juan Carlos Onganía became the leader of the new authoritarian regime, which dispensed with congress and all existing political parties and assumed all legislative and executive power for an indefinite period.

One of the first and most controversial measures of the new regime was its decision to deprive the universities of their autonomy and place them under the central control of the ministry of education. This decision led to violent clashes between the police and students. (X.)

V. POPULATION

1. Number and Distribution.—The census of 1947, the first since 1914, showed the population of Argentina to be 16,052,765, or the equivalent of 15.0 persons per square mile. By 1960 the total was 20,008,945 or 18.7 persons per square mile. In 1947 almost one-fifth of the population lived in the federal capital (in 1960, 15%), and 4,272,337 (26.6%) in Buenos Aires province. Almost one-half resided either in the capital or in the adjacent province of Buenos Aires in 1960. (*See* Table.)

Population in Argentina by Major Civil Divisions in 1960

Divisions	Area (sq. mi.)	Population	Persons per square mile
Total of the country	1,553,844	20,008,945	12.9
Total excluding antarctic sector and islands of the Atlantic	1,072,067	1,072,067	18.7
Provinces			
Federal Capital	77	2,959,746	38,438.1
Buenos Aires	118,753	6,707,498	56.5
Catamarca	38,540	168,231	4.4
Córdoba	65,161	1,762,803	27.1

Santiago del Estero	52,222	476,503	9.1
Tucumán	8,697	773,972	89.9
Federal territory of Tierra del Fuego, islands of the Atlantic			
Continental sector	7,873	7,955	1.0
Antarctic sector and other islands	481,777	...	...

Argentina is distinguished by the extent to which its people live in cities and towns. In 1960, 72% of the population was classified as urban; that is, as living in centres of 2,000 or more inhabitants. More than 40% of all Argentines were residents of cities having 100,000 inhabitants or more; including metropolitan Buenos Aires, about 48% lived in the nation's 16 largest cities.

2. Composition.—Persons of the Caucasoid race constitute the overwhelming proportion of Argentina's population. Most of them are descendants of immigrants from European countries who arrived after 1850. Full-blooded Indians are few in number, probably not more than 60,000, but approximately 10% of the population consists of mestizos. The numbers in these categories were increased considerably by influxes of persons from Paraguay and Bolivia, those from the former to work largely as domestic servants in the city of Buenos Aires and those from the latter in jobs on sugar plantations. Negroes and mulattoes are practically absent, the total number in both categories probably not exceeding 15,000. Asians, mostly Japanese, likewise are few in number, probably totaling less than 7,000.

The various censuses show that the foreign-born have consistently made up very high proportions of Argentina's population, the exact percentages being as follows: 1895, 25.4; 1914, 29.9; and 1947, 15.3. Of the 2,435,927 persons of foreign birth enumerated in 1947, the largest numbers had originated in Italy, Spain, Poland, the U.S.S.R., Paraguay, Uruguay, Germany, Chile, Bolivia, Brazil, France, Austria, Syria, Yugoslavia and Portugal, in that order. After the 1947 census was taken, immigration frequently exceeded 100,000 per year, and a large share of those admitted came from European countries, especially Italy and Spain.

Argentina's population has been heavily concentrated in the productive ages of life. In 1960, 52.4% of its people were aged 14–49; 28.8% under 14; and only 18.3% were 50 or over. Immigration also has been responsible for the high proportions of males in the population. Specifically, the number of males per 100 females was 111.9 in 1895, 115.5 in 1914, 105.1 in 1947, and 100.6 in 1960.

According to the 1947 census of population 14,880,246 (93.6%) of Argentina's people professed the Roman Catholic religion. The other faiths were represented by the following numbers: Protestants of all denominations, 310,633; Jews, 249,330; Eastern Orthodox, 66,217; other Christians, 2,125; Muslims, 18,764; other religions, 11,974; without professed religion, 239,949; and undeclared 114,589.

(*See* also *The People*, above.)

3. Growth of Population.—During the period 1914 to 1960 the population of Argentina increased at the rate of 1.8% per annum, one of the highest rates registered among the populous nations for the period. In earlier decades, however, the rate was even higher, averaging 3.7% per year during the intercensal period 1895–1914. After 1960 the increase probably did not exceed 2% per year. Immigration has figured to a considerable extent in the growth of population, but even so the excess of births over deaths is the principal reason for the rapid increase that has taken place. In 1960 the birth rate was about 25 and the death rate approximately 10 per 1,000 inhabitants, and it is unlikely that either of these changed substantially after that time.

Growth of population has been much more rapid in Argentina's cities and towns than in the rural districts. This is reflected in the fact that as the nation's population increased from 7,885,237 in 1914 to 16,052,765 in 1947, the proportion of the inhabitants who resided in urban districts rose from 52.7% to 62.5%. During the same intercensal period, the urban population increased 139% and the rural population by only 60%. Between 1947 and

1960 the difference between urban and rural growth rates was 48.5% to 15.2%. (T. L. Sh.)

VI. ADMINISTRATION AND SOCIAL CONDITIONS

1. Constitution and Government.—A federal union of 22 provinces, 1 territory, and a federal capital (coterminous with the city of Buenos Aires), Argentina has a form of government similar to that of the United States. The Argentine constitution of 1853 was modeled after that of the United States, and the similarities between the two are so marked that, in a famous decision, the Argentine supreme court once said:

> The system of government that rules us is not our creation. We found it in action elsewhere, tested by long years of experience, and we have appropriated it. And it has been said with reason that one of the great advantages of this adoption has been the existence of a vast body of doctrine, a practice and a jurisprudence that illustrate and fulfill the fundamental rules, and that we can and must utilize with regard to everything that we do not wish to alter because of our peculiar circumstances (*in re* Lindo de la Torre 19 CSN 236, 1887).

Nevertheless, there are some major differences between the two constitutional systems. One of the most important is that in Argentina power is somewhat more centralized in the national government, which under certain conditions can intervene in the administration of the provinces. The constitution of 1853 was modified in 1860, 1866 and 1898. It was superseded in 1949 by a new constitution, but was restored by a decree of the provisional government on May 1, 1956.

Under the constitution of 1853 legislative power is vested in a congress of two chambers: the senate, composed of two members for each province and two from the federal capital; and the chamber of deputies, with the number of inhabitants per deputy fixed by law, with periodic reapportionment provided for. Senators must have been Argentine citizens for at least six years before their election, and deputies for four years. Senators are elected by the legislatures of the provinces (and in the federal capital by a special body of electors) for terms of nine years, one-third renewed every three years. Deputies are elected by direct popular vote for four years, one-half renewed every two years.

The president and the vice-president of the republic are elected by electors voted for by the people. Their terms are six years and they may not immediately succeed themselves. They must be native-born citizens of the Roman Catholic faith. The president is commander in chief of the armed forces and appoints all civil, military, naval and judicial officers. The vice-president is the presiding officer of the senate. The president in his executive capacity is assisted by a cabinet of ministers appointed by him. There is a complex system of universal suffrage in national elections. Compulsory voting, enforced by fines, is required of all Argentine citizens over 18 years of age who are not deprived of the vote by law. Woman suffrage has been in effect since 1947. Clergymen and members of the regular army are prohibited from voting.

The judicial system is comprised of federal and provincial courts. The judges of the federal supreme court, the five courts of appeal and the district courts, one at least in each province, are appointed for life by the president, with the approval of the senate.

Each province has its own constitution and its governor, legislators and provincial functionaries, and each has its own judicial system. The governor of the territory is appointed by the national executive. The executive of the city of Buenos Aires, the federal capital, is appointed by the president. The city is separate from the province of Buenos Aires.

2. Living Conditions.—Working conditions, including the length of the working day, wage rates and the question of the rights and obligations of workers to become members of organized unions, have been major political questions in Argentina since the 1890s. On two chief occasions during the 20th century—during the administrations of Pres. Hipólito Irigoyen and again during the Perón period—the country had governments that, in seeking the political support of workers, translated into law measures providing for shorter working hours, higher wages and a strengthened organized labour movement. The bulk of these measures, although political conditions changed, remained in force. The Confederación General del Trabajo (C.G.T.) has been a major interest group in the country since the 1930s and, during the Perón period, developed a strongly political orientation. Approximately two-thirds of all employed workers were members of organizations affiliated with the C.G.T. Housing conditions in general reach a higher standard in Argentina than in other Latin-American countries. Nevertheless, adequate housing for workers and for the lower-income groups has long been a problem in the country. Widespread construction of low-rental housing was stimulated by Perón in an attempt to improve the living conditions of these groups.

3. Welfare Services.—Until the Perón period, organized and

systematically planned social welfare was virtually unknown in Argentina. Many of the relevant problems had been handled largely as a matter of charity. A good deal of this had been dispensed by the aristocratic Society of Philanthropy, whose membership was a species of who's-who of the upper classes. In 1948, however, under the leadership of Eva Perón, the María Eva Duarte de Perón Social Aid foundation was established as a quasi-governmental agency. The foundation gave financial aid and assistance in finding employment for the needy, and also constructed housing units, schools and hospitals. Although the bulk of the foundation's work was conducted within Argentina, the agency also made emergency and disaster relief available in other countries. The foundation itself was abolished in the mid-1950s, after establishing the precedent of social welfare as a rational public program, replacing the earlier tradition of relief of the needy through the philanthropy of the wealthy. Argentina has one of the most extensive social security programs in Latin America. Provision is made for health and maternity benefits, compensation for workmen injured during the course of their employment, severance pay for those who lose their jobs, family allowances for the unemployed and financial assistance to the aged and indigent. In health and sanitation, Argentina has historically been one of the best-situated countries in Latin America.

4. Education.—Argentina's possession of one of the finest educational systems in the western hemisphere dates from the administration of the "schoolmaster president" Domingo Faustino Sarmiento. Under Perón, the schools suffered in quality primarily because of the suppression of academic freedom, but the number of persons receiving this poorer education increased as many new schools were built and most Argentine educational institutions became tuition-free. There are about 2,900,000 pupils in the country's primary schools and about 775,000 in its secondary and technical schools. The oldest university, the University of Córdoba, was founded in 1613. The other major centres of higher education are the universities of Buenos Aires, La Plata, Santa Fe and Tucumán. Literacy is estimated at 91.4%, one of the highest rates in Latin America.

5. Defense.—The armed services, especially since 1930, have been highly important in Argentine national life. Of the 11 presidents of the country between 1930 and 1960, 8 were army officers. During the Perón period, all men and women between the ages of 12 and 50 were subject to military service. As of the early 1960s, men between 20 and 45 were required to serve at least one year of active duty in the armed forces, and at least three years in the reserve. At that time, the armed services had more than 500,000 men.

The Argentine navy had its origins in the wars of independence, during the second decade of the 19th century. Although its record in that, as well as in later wars, was a commendable one, it was not until the closing years of the century that boundary disputes and the threat of war with Chile induced the government to develop an appreciable navy. In the 20th century a keen naval rivalry with Chile and, later, Brazil, was maintained. (G. I. B.)

VII. THE ECONOMY

The cities in the eastern foothills of the Andes—Santiago del Estero, Salta, etc.—were founded by Spaniards who crossed the mountains into Argentina from Peru and Chile. During the colonial period they prospered on their trade with the silver-mining regions in the Andes and the Spanish possessions on the Pacific side of the Cordillera—for example, mules were fattened on the pastures around Salta, to be sold in the arid altitudes of Bolivia, where they were the only means of transport. Meanwhile, the faraway Plata estuary, being remote from any mineral resources, was neglected. Buenos Aires remained a dreary little town, prohibited from engaging in direct commerce with the outside world; all its trade had to be conducted across the continent by way of Lima, which was the political and economic centre of Spain's empire in southern South America. Transport by mule and ox cart on the long overland route was slow and costly.

It was not until the end of the 18th century, when the authorities in Madrid relaxed these restrictions, that the Plata was freed from the economic domination of Lima. From that time, Argentine hides, skins, tallow, horns and wool could be exported directly from Buenos Aires by sea, and manufactured goods could be imported directly from Europe, at about one-third of their previous cost. One hundred years were to pass before the invention of the refrigerator ship, which made it possible to send meat through the tropics for delivery in edible condition to the industrial populations of the old world.

Argentina's economic centre thus was transferred from the Andes to the Atlantic region. As a result, the cities in the Andean foothills declined into poverty. But the opening of the pampas' natural outlet was an essential step toward the future prosperity of the nation. The Plata estuary was also the natural entry for the European immigrants and the equipment which, after the fall of Rosas, transformed the pampas into one of the world's greatest sources of meat and grain. The provinces resented the growing wealth of Buenos Aires, which arose from its virtual monopoly of the handling of exports and imports. Nevertheless, when the provincial coalition of 1880 had defeated the Buenos Aires army, the victorious landowners themselves quickly saw that the captured city was the inevitable focal point of the republic. This landowning aristocracy therefore set about making Buenos Aires even more powerful than it had been before by providing it with a new port and by extending the railways, which carried everything to its docks, to distant regions. From Buenos Aires they bound Argentina to Great Britain and Europe by commerce and by the loans they contracted to finance their projects.

Economic development was accompanied by extravagance and speculation. The bubble burst in 1890, bringing disaster to the overoptimistic firm of Baring (*q.v.*) Brothers of London. But confidence soon revived, and after 1895 foreign funds were again arriving. By 1912 about 20,000 mi. of railways had been built; vast areas had been plowed and sown with alfalfa (*i.e.*, lucerne, for fodder) and cereals; huge pastures had been fenced in with barbed wire; all over the pampas metal windmills had been erected to pump water to the surface for the livestock; pedigree bulls and rams had been imported to improve the local breeds.

Argentina was rich indeed, but it was dependent on Great Britain and Europe for the disposal of its primary products and for obtaining the manufactures and essential commodities, such as coal, which it lacked. The weakness of this so-called "colonial" type of economy was felt during World Wars I and II, when the flow of imports was interrupted, and during world-wide economic crises, such as that of 1930, when a slump in foreign demand for meat and grain caused distress and bankruptcy. It became apparent that industry must be developed so that some degree of economic independence might be attained. Wartime shortages encouraged industrial expansion, and after 1945 President Perón used foreign exchange profits to hasten the process.

The growth in imports of machinery, raw materials and fuels that inevitably accompanied industrialization was not matched by increased exports of pastoral and agricultural products. Indeed, the growing urban population of Argentina itself made ever greater demands on the nation's production of meat and grain. President Frondizi's austerity program in 1959 succeeded in eliminating the country's foreign trade deficit. Another surge of industrial development followed in 1960 and 1961. Foreign investment was considerable, but the volume of short-term foreign borrowing in that period led to another balance of payments crisis in 1962, followed by a prolonged and serious economic recession from which the country began to recover only in mid-1963. As a founder-member of the Latin American Free Trade Association (L.A.F.T.A.) which was set up in 1960, Argentina has sought to increase its trade with its neighbours, particularly in the export of manufactured goods. A five-year national development program was announced at the end of 1964.

A. Production

Argentina lacks so many of the basic resources necessary to a modern industrial economy that it is difficult to conceive of a time when the fertility of its soil will have ceased to be its greatest asset. Recognizing that industrialization depends on a high level

of rural exports, 20th-century governments have endeavoured to stimulate rural production by guaranteeing minimum prices to cattle raisers and farmers, granting credit facilities and loans, and other devices. Rural output still comes mainly from large-scale ranches and farms, whether owned privately or by joint stock companies, although by the middle of the 20th century an increase had occurred in the number of small holdings.

1. Livestock.—Conditions in the pampas are extraordinarily favourable to natural pasture and the cultivation of alfalfa. Moreover, cattle can be grazed there throughout the year without need for shelter. But the number of animals has not corresponded to the growth in the human population. In 1895 Argentina had about 5.4 head of cattle per inhabitant, while by the 1960s it had about 2. The total number of cattle varies according to world conditions and government incentives and is sometimes affected by drought, which may cause serious losses. During the mid-1960s the estimated stock of cattle averaged 41,000,000–43,000,000 head. The chief breeds are Shorthorn, Aberdeen Angus and Hereford. The highest grade of beef cattle is produced, but the methods generally are not up-to-date and the number of animals per acre could be increased if the pastures were improved. Foot-and-mouth disease in a mild form is endemic. In addition to meat in its various forms, cattle hides and calfskins are important items for export.

Sheep are bred in many parts of the republic, especially in Patagonia (where the land, however, has been overgrazed) and on the pampas. The number of sheep varies according to fluctuations in the price of wool, but the total tends to rise year by year. By the mid-1960s there were about 48,000,000 head. The favourite breeds are Corriedale (in Patagonia), Lincoln (on the pampas), Merino and Romney Marsh. More than one-half the flocks are crossbred. About one-third of the wool is used by local textile manufacturers. After the Uruguayans, the Argentines are the world's biggest meat eaters (as much as 240 lb. annually per inhabitant), but they prefer beef to mutton.

2. Agriculture.—The length of the republic from north to south is so great (2,294 mi.) that almost every type of climate exists somewhere within its borders and almost all crops can be grown. The whole of the most fertile part of the country, the humid pampa, is already in use for pasture and the cultivation of grain; so throughout that region livestock and cereals are in competition for the land. When world prices, government incentives, labour shortages or rising costs of wages and agricultural machinery lead to the expansion of cattle raising (which is less dependent on labour and machinery), the area planted with cereals is reduced. When prices or incentives encourage the sowing of crops, pastures are encroached upon and plowed up. In the future, therefore, if cattle raising is to be increased, the only possible means of simultaneously raising the production of cereals will be by intensive technological improvement, including the use of better seeds, fertilizers and more mechanization.

The grain belt extends through the provinces of Buenos Aires, Córdoba, Entre Ríos, La Pampa and Sante Fe. The chief crops are wheat and corn. Wheat is sown from April to August, according to latitude, and is harvested from November to January. Corn is sown from August to October and harvested from March to June. As corn harvesting is done by hand, the cultivation of this grain in particular has suffered from the departure of rural workers, who have gone to the factories in the towns to earn higher wages. Other cereals are barley, oats and rye. Oilseeds include linseed and sunflower. Argentina also is self-supporting in cotton (grown mainly in the hot regions of the Chaco and Formosa), sugar cane (mostly in Tucumán), rice (Corrientes, Entre Ríos and Santa Fe), tobacco (Corrientes and Salta), tung (Misiones) and yerba maté (Misiones).

Citrus fruits are grown in the central and northern provinces; apples and pears in Río Negro and Mendoza; plums in Mendoza; peaches in Buenos Aires and Mendoza; and grapes in Mendoza, San Juan and Río Negro. In these last three regions the orchards and vineyards are irrigated. Deciduous fruits are exported to Brazil and the United Kingdom.

3. Forestry, Mining and Fisheries.—The most valuable tree is the quebracho, which grows in the Chaco and provides tannin extract. It is also used for railway ties (sleepers) and fencing. But the forests easily accessible from the rivers have been denuded, and every year the quebracho cutters have to travel farther inland in search of trees. As the quebracho takes a century to reach maturity, no reafforestation has been attempted. Softwood is imported. Forests in the southern Andes as yet are almost unexploited.

Small deposits of lead, zinc, iron ore and some other minerals are mined, mainly in distant Andean regions.

In spite of the country's extensive coast line, its many rivers and its southern lakes, fishing is of little importance in the national economy. The government has tried to encourage this activity (hoping thereby to reduce the local consumption of meat), but fish is not a popular food.

4. Fuel and Power.—In the necessary endeavour to industrialize, Argentina's chief problem is the inadequacy and geographical remoteness of its resources of fuel and power. Although consumption of fuel and power is still low by United States and European standards, it more than doubled in the three decades after 1930, and expenditure on importing petroleum in particular became an increasing drain on foreign exchange.

Petroleum is obtained in the Andean regions of Salta, Mendoza

OPENING OF "LA RURAL," YEARLY AGRICULTURAL SHOW HELD EACH WINTER IN BUENOS AIRES. THE SHOW BEGINS WITH THE PARADE OF PRIZE-WINNING ANIMALS AND ENDS WITH THE SALE OF THE ANIMALS AT AUCTION

ILSE MAYER—PIX FROM PUBLIX

and Neuquén, and at Comodoro Rivadavia in Patagonia. Production by the state-controlled organization Yacimientos Petrolíferos Fiscales (Y.P.F.) continued to rise year by year but did not keep pace with the growing demand. Foreign participation on an adequate scale was long delayed because nationalist sentiment prevented the granting of sufficiently attractive concessions. In 1958 President Frondizi decided to negotiate a number of contracts with foreign companies whereby they would explore and exploit local oil resources as agents of Y.P.F., which would continue to safeguard national sovereignty over the oil. Domestic output increased rapidly, with a corresponding reduction in fuel imports and saving of foreign exchange. New refineries were planned, to supplement those already existing at La Plata and San Lorenzo (on the Río Paraná). However, soon after taking office in 1963 President Illia's administration annulled the petroleum contracts, alleging that they were illegal and contrary to the national interest. Several long pipelines convey natural gas and oil to centres of population and industry. The most ambitious of these undertakings is the pipeline that brings natural gas from Comodoro Rivadavia to Buenos Aires, a distance of 1,000 mi.

Almost all coal is imported. A little is mined at Río Turbio in Patagonia and smaller quantities in Mendoza and San Juan.

Production of electricity is insufficient, the unexploited sources of hydroelectric power, notably the Iguaçu (Iguazú) falls, being very remote from the industrial region. Hydroelectric plants have been built in the provinces of Mendoza, Río Negro and Córdoba. One of the largest of several thermoelectric projects is the station at San Nicolás, well-placed on the Paraná river and designed to supply Buenos Aires, Rosario and lesser towns.

5. Industry.—Argentina's basic industries have always been those devoted to processing the produce of the land. Manufacturing is largely concentrated in or near Buenos Aires but, as a result of an official decentralization policy enunciated in the 1950s, factories began to be built in greater numbers in several other riverside cities and in the interior, notably at Córdoba.

The important meat packing industry is mainly foreign owned, with about 50% United States and 20% British capital, but it is subject to government controls of many kinds. Meat is chilled, frozen and canned in the *frigoríficos* (packing plants) for export. Leather working is one of the oldest industries in the country. The largest of the manufacturing industries are those turning out woolen and cotton textiles. Argentina is self-supporting, too, in almost all other consumer goods (except in the luxury qualities).

By the second half of the 20th century the establishment of heavier industries had begun, often with state participation. A modern steel mill at San Nicolás produces billets, rails, structural steel, plates, rolled sheets, tin plate, etc. This plant, however, is almost entirely dependent on imported iron ore and coal. Encouraged by a special promotion scheme, the production of motor vehicles developed rapidly after 1959 into one of the country's leading industries, centred in Buenos Aires and Córdoba.

B. Trade and Finance

1. Exports and Imports.—Argentina's principal exports (in order of value, though this order varies slightly from year to year) are cereals and linseed; meat; wool; hides; dairy produce; wheat meal and flour; quebracho extract and other forest products; and animal by-products. The chief destinations of exports (the order of importance may vary slightly) are the United Kingdom, the Netherlands, the U.S., Italy, the Federal Republic of Germany and Brazil. Principal imports are machinery and vehicles; fuels (which are declining in volume) and lubricants; iron and steel; chemicals; wood; and nonferrous metals. The chief suppliers are the U.S., the Federal Republic of Germany, Venezuela, the United Kingdom, Brazil, Italy, Belgium and France.

2. Banking and Finance.—Argentina's banking system dates from the economic crisis of the 1930s. The powerful Banco Central was created in 1934 as a national institution to carry out the government's monetary and economic policies. Among its many functions, it regulates the volume of credit and money supply; it is the bank of issue and rediscount; and it serves as agent for international payments. The state issues investment credit through three state-owned banks, the Banco Industrial, the Banco Hipotecario Nacional and the Banco de la Nación Argentina, which is the largest of the commercial banks.

Foreign investment, which performed such a vital role in the development of Argentina's "colonial" economy, was greatly reduced in the years immediately following World War II, when President Perón's policy of nationalization was in force. Besides the petroleum industry, the state now controls such enterprises as the railways, merchant marine, air services, telephones, port facilities, grain elevators and military factories.

At the time of Perón's overthrow, Argentina was suffering from severe inflation, an adverse balance of payments and a depreciated currency. In Oct. 1955 the peso was officially devalued to a rate of 18 to the U.S. dollar (50.03 pesos to the pound sterling); but this proved to be an overvaluation, and the peso continued to decline during the following years.

President Frondizi's austerity program, inaugurated in Jan. 1959, provided for abolition of the official rate of exchange and import permits (the latter were replaced by surcharges to discourage nonessential imports); the restriction of bank credit; and the removal of price controls in the domestic market and subsidies. To support the program, credits were granted to Argentina by the International Monetary fund, the Export-Import bank and other official and private U.S. agencies. The peso, freed to find its own level, fell abruptly, finally settling at a fairly stable rate of about 82.5 to the U.S. dollar (232 to the pound sterling). The cost of living rose by about 102% in 1959, but thereafter it rose much less steeply.

A further depreciation of the peso in the exchange market began in 1962 when the Central Bank withdrew its support. By the late 1960s the peso was valued at about 350 to U.S. $1. The annual national budgets in the 1960s showed considerable deficits, one of the principal causes being the heavy operating loss of the state railways.

C. Transport and Communications

A 19th-century Argentine statesman declared that the most formidable obstacle to the country's progress was distances. As far as immediate needs were concerned, this obstacle was then overcome by the construction of the railways (financed, equipped and directed mostly by British companies). The railway system was planned, however, with the single purpose of carrying the pastoral and agricultural produce of the pampas to the eastern river ports and Bahía Blanca. There are now about 27,000 mi. of railways, but about 70% of the track is still concentrated in the pampas (which amounts to only one-fifth of the total area of the republic). The railways provide no communication with the southern oil fields and many other regions that urgently require development. Re-equipment of the railways was interrupted during World War II and they were in a somewhat dilapidated condition when they were bought by the government in 1948 for £150,000,000. Thereafter Argentina lacked sufficient foreign currency for their rapid rehabilitation.

The highway system is inadequate for modern needs. Paved roads connect the principal cities, but most of the lesser roads are unpaved and often unusable in wet weather.

The state-owned merchant fleet was greatly enlarged during the Perón regime. Almost all Argentina's foreign trade is carried by sea. The Paraná river is an important inland waterway connecting upstream districts with Buenos Aires. The state-owned airlines provide internal services and regular flights to other Latin-American countries, the U.S. and Europe. There is a large, up-to-date airport at Ezeiza, on the outskirts of Buenos Aires.

Argentina has more telephones per 100 inhabitants than any other Latin American country. However, with more than 1,000,000 lines in operation in the mid-1960s the state service was by no means adequate and there was a considerable backlog of requests for telephones. Private cable companies and a telex service provide external communications.

A government television channel has operated in Buenos Aires since 1951; other channels in the capital and the provinces began operating after 1960.

ARGENTINA, LA (ANTONIA MERCÉ) (*c.* 1888–1936), greatest Spanish dance artist of her generation, was born in Buenos Aires about 1888. Both her parents were Spanish and professional dancers. La Argentina began studying ballet at the age of four under her father's instruction. At 14 she turned to Spanish dancing and shortly thereafter began to appear in the *cafés* of Spain and Latin America. At the end of World War I, Paris enthusiastically acclaimed her creative artistry. Concert engagements throughout Europe followed, and for 15 years she toured almost constantly. She made six concert tours of North America, three of South America, and was the first Western dancer, after Pavlova, to tour the Orient. She traveled without a company, her entire program being made up of her creative solos performed to piano accompaniment. She died at her home in Bayonne, France, on July 18, 1936.

La Argentina is universally recognized as the greatest of creative Spanish dance artists. Her treatment of this art established the Neoclassic style. She revived the essential nobility of the Spanish dance and, with unerring musical talent, interpreted the music of Iberian classical composers. Her control and musical understanding of castanets remain unsurpassed.

LA ARGENTINITA (*c.* 1900–1945), Spanish dancer whose fame rivaled La Argentina's, was also born in Buenos Aires and similarly used the name of her native country (in the diminutive form) as her stage name. Her childhood and early years as a dancer were spent in Spain. In 1932 she collaborated with the poet F. García Lorca in forming the Madrid Ballet. She toured Europe and North and South America with her own small company from 1935 until her death in New York City on Sept. 24, 1945.

(R. M. HS.)

ARGENTITE, a mineral consisting of silver sulfide. It occurs in mineral veins, and when found in masses, as in Mexico and in the Comstock lode in Nevada, it is an important ore of silver. It is occasionally found as uneven cubes and octahedra, but more often as compact masses, with a blackish lead-gray colour and metallic lustre. Silver sulfide is cubic in crystallization only at temperatures above 91° C; the cubic crystals found in nature are really paramorphs, consisting of an intricate lamellar aggregate of orthorhombic crystals. The orthorhombic modification of silver sulfide stable below 91° C is the mineral acanthite. Argentite is perfectly sectile, or can be cut with a knife, and has a shining streak. The formula is Ag_2S, the hardness 2.5 on Mohs' scale, and the specific gravity 7.3. (CL. F.)

ARGILLITE is a fine-grained, well-indurated, fairly hard, clayey rock. It differs from clay and shale in being harder and in disintegrating or slaking less readily in water. Argillite has undergone some recrystallization as a result of compaction and metamorphic processes. In this way it also differs from clay and shale, which have undergone substantially no metamorphism, and from slates and schists, which have suffered greater metamorphic changes. The hardness of the rock, the mineral composition and the texture are to a considerable degree the result of metamorphic changes.

There are two slightly varying uses of the term. One limits the term to rocks which do not have a laminated structure; in the other the term applies only to rocks which do have a laminated structure and are intermediate in hardness between shale and slate. The first usage is probably the most general in both the United States and Europe. Except for some use in making portland cement, argillite has slight commercial value. (R. E. GM.)

ARGINUSAE, the ancient name of a group of islands off the coast of Asia Minor, opposite the southern end of Lesbos, and the scene of the last Athenian victory in the Peloponnesian War (August 406 B.C.). The Athenian admiral Conon having been blockaded by superior Spartan forces in Mitylene, the Athenians, by ruthless conscription of their last resources of men and wealth, raised a fresh fleet which engaged the Spartans and defeated them heavily. A storm rose and the eight generals in charge of the Athenian fleet retired to shelter without attempting to rescue the Athenian sailors on the 12 triremes that were sinking. Six of the generals, Aristocrates, Diomedon, Erasinides, Lysias, Pericles (son of the statesman), and Thrasyllus were in the same year tried before the assembly for negligence and executed.

ARGON, a chemical element, is a colourless, odourless, and tasteless gas. It is the most abundant of the family of noble gases, accounting for almost 1% of the earth's atmosphere, and is commercially the most important. Argon is obtained from liquid air by a fractionation process and has a variety of applications, usually based on its inertness. Its chemical symbol is Ar; the atomic number is 18; and the atomic weight is 39.942.

Argon is not known to form stable compounds with other elements. The discovery in 1962 that xenon (*q.v.*) will combine with platinum hexafluoride and with fluorine itself toppled the theory that no member of the noble-gas group (formerly called the inert gases) would form a stable compound, but subsequent attempts to effect an argon-fluorine bond failed.

History.—Definite evidence for the existence of some inert constituent in the earth's atmosphere was obtained by Henry Cavendish (*q.v.*) as early as 1785 while trying to determine whether atmospheric nitrogen ("phlogisticated air") was homogeneous or a mixture of different substances. In these experiments a mixture of air and oxygen was sparked over potash, which absorbed the oxides of nitrogen formed. After the removal of excess oxygen there remained a small bubble of gas which could not be diminished by further sparking with oxygen. It is now known that the residue must have consisted mainly of argon, but Cavendish did not pursue the experiments further. He concluded that "if there is any part of the phlogisticated air of our atmosphere which differs from the rest, and cannot be reduced to nitrous acid, we may safely conclude, that it is not more than $\frac{1}{120}$ part of the whole."

This evidence was overlooked for more than a century, until Lord Rayleigh, in the course of accurately redetermining the densities of the principal gases, found that the density of atmospheric nitrogen was always about 0.5% greater than that of nitrogen derived from chemical sources; *e.g.*, from ammonia or nitrous oxide. This pointed to the presence of an unknown gas and brought to light the earlier work of Cavendish. The gas, called argon (from the Greek *argos*, "idle") because of its chemical inertness, was finally isolated in 1894 by Lord Rayleigh and Sir William Ramsay (*q.v.*), who employed a method similar to that of Cavendish.

They also obtained the gas by passing air over heated copper, to remove the oxygen, and then over heated magnesium, which removes the nitrogen as nitride. They also showed, by measurement of the ratio of the specific heats at constant pressure and constant volume, that the energy absorbed on heating is wholly translatory and that the gas must therefore be monatomic. Argon was the first of the noble gases to be isolated from a terrestrial source. (Helium had been detected in the sun in 1868.)

Scientific Importance.—The discovery of argon was of profound scientific importance, because it provided the starting point for many great developments in chemistry and atomic physics. It led directly to the terrestrial discovery of the other noble gases and so completed, in form at least, the periodic classification of the elements. (*See* PERIODIC LAW.) At the time of the discovery of argon there were a number of gaps in the periodic table (later gradually filled). Most of these gaps represented isolated missing elements whose properties could be predicted with some certainty. But the presence of an entire new group of elements, apparently of zero valence, was totally unsuspected. In a search for other sources of argon Ramsay examined the mineral cleveite, which is mainly uranium oxide, and isolated not argon but helium (*q.v.*), a much lighter gas. This element proved to be the first member of the new family. Three other members, krypton, xenon, and neon (*qq.v.*), were isolated soon afterward. The general chemical inactivity of these gases and the correlation of this fact with their outer complete octet of electrons constituted a fundamental feature of the theory of valence (*q.v.*), which postulates that all atoms strive to attain the stability of this simple octet and that the sharing and exchanging of electrons which goes on in the process is the source of all chemical change.

In another direction, the discovery of argon led to the immediate understanding of the true nature of two important products of radioactivity: helium, which is produced spontaneously as alpha-particles; and the intensely radioactive gas known as radium emanation, or radon (*q.v.*), which proved to be the last member of the noble gas family, after xenon. Interpretation of the phenomenon of radioactivity and all the knowledge of the structure of atoms which followed would thus have been indefinitely delayed and complicated but for the far-reaching discovery of Ramsay and Rayleigh.

Uses.—The most important industrial use of argon is in so-called gas-filled electric lamps. (*See* LIGHTING: *Electric Discharge Lamps.*) It makes an ideal inert atmosphere. To prevent arc formation, however, a little nitrogen is generally added. Argon has also been used in vapour-pressure thermometers for use at very low temperatures; as a carrier gas in chromatography (*q.v.*); and for filling ionization chambers and proportional counters (*see* NUCLEAR INSTRUMENTS) for the measurement of X-ray intensities.

Production.—The methods already described (*see* above, *History*), although laborious, produce small quantities of argon. A mixture of pure dry lime and magnesium powder may also be used. When heated to redness the mixture yields metallic calcium, which reacts with atmospheric nitrogen to give the nitride, Ca_3N_2, leaving argon.

For large-scale production the removal of both nitrogen and oxygen in one operation by passing air slowly over heated calcium carbide is a more suitable process. In this reaction carbon dioxide (which is easily removed) and calcium cyanamide, $CaCN_2$, a solid, are formed. This process was used for the first commercial production of argon in quantity in the U.S. in 1914.

None of the above methods is capable of separating argon from the other noble gases which are present in very small amounts in the atmosphere (*q.v.*). Separation can be effected by the fractionation of liquid air, the process now exclusively used in the large-scale industrial production of argon. (*See* DISTILLATION: *Fractional Distillation and Rectification.*) The boiling point of liquid argon, −185.7° C, is intermediate between that of nitrogen (−196°) and oxygen (−182°). Helium and neon have much lower boiling points and can therefore be isolated from the more volatile fraction, while the higher boiling points of krypton and xenon ensure that they are retained in the less volatile fractions. But the argon is closely associated with the oxygen and nitrogen fractions, and these three gases together comprise more than 99.99% of the total. A rectification column consisting of a number of plates, with taps at different levels, is employed. The argon accumulates on the lower plates of the column, and at a certain point gas containing about 10% argon, mixed mainly with oxygen, can be withdrawn. This gas must then be redistilled, or rectified, in a separate column, and finally the remaining oxygen can be easily removed by combustion. The gas obtained in this way is reasonably pure, although traces of the other noble gases still remain. These do not interfere with its main use, in the electric lamp industry; but if chemically pure argon is required, further processes of fractional condensation and evaporation and also fractional adsorption (*q.v.*) over charcoal may be employed.

Physical and Chemical Properties.—Argon is monatomic. The 18 electrons are arranged in shells, 2, 8, 8, the outermost shell being a complete octet, which gives the atom zero valence and apparent chemical inertness. It is known to exist in three naturally occurring isotopic forms, of mass numbers 40, 38, and 36, the relative abundances being respectively about 99.60%, 0.06%, and 0.34%. The atomic weight is therefore just a little below 40. The production of Ar^{40} from K^{40} decay is important as a means of determining geologic age (potassium-argon dating; *see* GEOCHRONOLOGY).

Argon condenses to a colourless liquid at −185.8° C and to a crystalline solid at −189.3° C. The crystal structure indicates a face-centred cubic lattice with *a* (cube edge) = 5.42 Å (angstrom units), the contact distance between the argon atoms being 3.83 Å. The density of the liquid at −183° C is 1.374. The critical temperature is −122.4° C, the critical pressure 48 atm., and the critical density 0.509. The solubility of the gas in water is considerable, 3.94 vol. dissolving in 100 vol. of water at 12° C—this being more than double the solubility of nitrogen. The spectrum of argon is not outstanding and consists of many lines spread over the whole visual range. At low pressure the discharge is pale red in colour, changing to a steely blue when a condensed discharge is used.

Although no compounds involving normal bonds between argon and the atoms of other elements have been prepared, several complexes, of varying degrees of stability, have been recorded. At a pressure of 150 atm. and in the presence of ice, a hydrate of composition $Ar{,}5.5H_2O$ is obtained; it is extremely unstable, with a dissociation pressure of nearly 100 atm. Freezing-point data for the system boron trifluoride-argon indicate the formation of a series of unstable complexes of composition $Ar{,}BF_3$; $Ar{,}2BF_3$; $Ar{,}3BF_2$; $Ar{,}6BF_3$; $Ar{,}8BF_3$; and $Ar{,}16BF_3$. The most interesting and the best established "compound" containing argon is a quinol clathrate of composition $3C_6H_4(OH)_2 0.8Ar$, prepared by H. M. Powell (1950). The structure of this type of complex, fully established by X-ray analysis, consists of a cagelike arrangement of quinol molecules held together by hydrogen bonds. A cavity about 4 Å in diameter is formed between every three quinol molecules, and in these cavities various small molecules or large atoms can be trapped when the substance crystallizes. The argon clathrate is prepared by exposing a solution of quinol to argon at a pressure of about 40 atm. When the clathrate crystallizes out it is quite stable and contains almost the theoretical quantity of one argon atom to every three quinol molecules. In solution, however, the argon escapes with vigorous effervescence: it is clearly not bonded to any of the other atoms. A similar explanation probably applies in the case of some other complexes that have been described.

ARGONAUTS, in Greek legend, a band of heroes who went

with Jason (*q.v.*) to fetch the golden fleece in the ship "Argo." This task had been imposed on Jason by his uncle Pelias, who had usurped the throne of Iolcus in Thessaly, which rightfully belonged to Jason's father Aeson. The story of the fleece follows:

Jason's uncle Athamas had two children, Phrixus and Helle, by his wife Nephele, the cloud goddess. But after a time he became enamoured of Ino, the daughter of Cadmus, and neglected Nephele, who disappeared in anger. Ino, who hated the children of Nephele, persuaded Athamas, by means of a false oracle, to offer Phrixus as a sacrifice, as the only means of alleviating a famine which she herself had caused by ordering the grain to be secretly roasted before it was sown. But before the sacrifice, the shade of Nephele appeared to Phrixus, bringing a ram with a golden fleece on which he and his sister Helle endeavoured to escape over the sea. Helle fell off and was drowned in the strait, which after her was called the Hellespont. Phrixus reached the other side in safety, and, proceeding by land to Aea in Colchis on the farther shore of the Euxine (Black) sea, sacrificed the ram and hung up its fleece in the grove of Ares, where it was guarded by a sleepless dragon.

Jason, having undertaken the quest of the fleece, called upon the noblest heroes of Greece to take part in the expedition. According to the original story, the crew consisted of the chief members of Jason's own race, the Minyae. But when the legend became common property, other and better-known heroes were added to their number. The crew was supposed to consist of 50, agreeing in number with the 50 oars of the "Argo," so called from its builder, Argus, or from Gr. *argos* ("swift"). It was the first ship, or the first war galley, ever built. Athena herself superintended its construction, and inserted in the prow a piece of oak from Dodona, which was endowed with the power of speaking and delivering oracles.

The Argonauts arrived at Lemnos, which was occupied only by women, who had put to death their fathers, husbands and brothers, and there they remained several months. It is known from Herodotus that the Minyae had formed settlements at Lemnos at a very early date. Proceeding up the Hellespont, they sailed to the country of the Doliones, by whose king, Cyzicus, they were hospitably received. After their departure, being driven back to the same place by storm, they were attacked by the Doliones, who did not recognize them, and in a battle that took place Cyzicus was killed by Jason. After Cyzicus had been duly mourned and buried, the Argonauts proceeded along the coast of Mysia, where occurred the incident of Hercules and Hylas (*q.v.*). On reaching the country of the Bebryces, they again landed to get water, and were challenged by the king, Amycus, who forced all passing travelers to box with him in the hope of killing them. Polydeuces accepted the challenge and slew him. At the entrance to the Euxine, at Salmydessus, on the coast of Thrace, they met Phineus, the blind and aged king whose food was being constantly polluted by the Harpies. He knew the course to Colchis, and offered to tell it, if the Argonauts would free him from the Harpies. He was freed by the winged sons of Boreas, and Phineus now told them their course, and how to pass through the Symplegades or Cyanean rocks—two cliffs that moved on their bases and crushed whatever sought to pass. His advice was successfully followed: Jason sent ahead a dove, which was damaged between the rocks, but the "Argo" slipped through almost unscathed while the rocks were rebounding. From that time the rocks became fixed and never closed again.

After sundry minor adventures, the Argonauts reached Colchis. But the king, Aeetes, would not give up the fleece until Jason yoked his bulls (given him by Hephaestus), which snorted fire and had hooves of bronze, to a plow, and with them plowed the field of Ares. That done, the field was to be sown with the dragon's teeth, from which armed men were to spring. Aeetes' daughter, the sorceress Medea, who had fallen in love with Jason, gave him a salve that protected him from fire, and advised him to cast a stone at the newborn warriors to cause them to fight to the death among themselves. These tasks accomplished, Aeetes refused to give over the fleece, but Medea put to sleep the dragon that guarded it; Jason then carried off the fleece, with Medea. When Aeetes pursued them, to delay him and thus obtain escape, Medea dismembered her young brother Absyrtus, whom she had taken with her, and cast his limbs in the sea for his father to pick up. In another account Absyrtus had grown to manhood then, and met his death in an encounter with Jason, in pursuit of whom he had been sent.

Of the homeward course various accounts are given. In the oldest (Pindar), the "Argo" sailed along the river Phasis into the eastern Oceanus, round Asia to the south coast of Libya, thence to the mythical lake Tritonis, after being carried 12 days overland through Libya and thence again to Iolcus. Hecataeus of Miletus suggested that from the Oceanus it may have sailed into the Nile, and so to the Mediterranean. Others, like Sophocles, described the return voyage as differing from the outward course only in taking the northern instead of the southern shore of the Euxine. Some (pseudo-Orpheus) supposed that the Argonauts had sailed up the river Tanais, passed into another river, and by it reached the North sea, returning to the Mediterranean by the Pillars of Hercules. Again, others (Apollonius Rhodius) laid down the course as up the Danube (Ister), from it into the Adriatic by a supposed mouth of that river, and on to Corcyra. Then follow wanderings, partly based on those of Odysseus (*q.v.*), partly on the older Argonautic routes. Finally, they reached Iolcus, and the "Argo" was placed in a grove sacred to Poseidon in the isthmus of Corinth.

The story of the expedition of the Argonauts is very old. Homer was acquainted with it and speaks of the "Argo" as well known to all men; the wanderings of Odysseus may have been partly founded on its voyage. Pindar, in the fourth Pythian ode, gives the oldest detailed account of it. Apollonius Rhodius in the 3rd–2nd centuries B.C. artificially rendered the story as an epic, "The Argonautica," which still survives. In ancient times, the expedition was regarded as a historical fact, an incident in the opening up of the Euxine to Greek commerce and colonization, and so it probably is, but with a great accretion of fabulous details of many kinds.

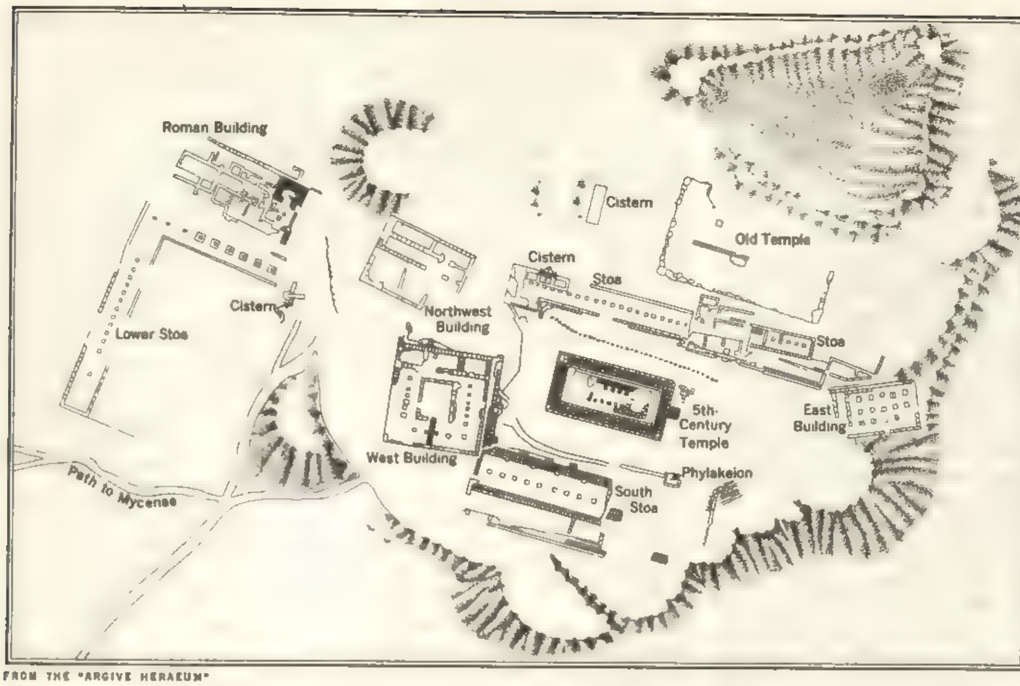
See J. R. Bacon, *The Voyage of the Argonauts* (1925), for further discussion and bibliography. (T. V. B.)

ARGONNE, a wooded, hilly area of eastern France, forms a natural barrier between Champagne and Lorraine. In the Lower Cretaceous rocks there is a local development of highly resistant sandstone that is responsible for this hilly massif, aligned south-southeast to north-northwest for more than 40 mi., with an average breadth of about 10 mi. The Aire and Aisne and their numerous tributaries dissect it with deep valleys, and the area has little, save strategic importance. The Prussians were repulsed by the French at Valmy in 1792. The Meuse-Argonne operation (Sept.–Nov. 1918) was a major victory engagement of U.S. forces in World War I. (Ar. E. S.)

ARGOS, a name apparently signifying an agricultural plain, which was applied to several districts in ancient Greece of which the most celebrated was the capital of the Argolis, or Argolid, a dry but fertile plain which still lives up to its Homeric epithets of "thirsty" but "fertile" and "horse-rearing." The plain is encircled by mountains, but easy passes connect it with the modern *nomos* of Korinthia on the north, with the Arcadian highlands on the west and with the district of Epidaurus on the southeast. The chief harbour must always have been at Nauplia (*q.v.*), and the city-state of Argos was always a land, not a naval power.

History.—Traditionally the city was said to have been founded by the mythological Phoroneus the son of the river-god Inachus about 1750 B.C. Derivations of a royal family from a god frequently imply that the human founder arrived as an invader, and this date is compatible with that assigned by many philologists and archaeologists to the arrival of the first Greek-speaking people (the beginning of the 2nd millennium B.C.), who probably introduced the gray wheelmade pottery termed gray Minyan. A settlement of these people was revealed on the hill called the Aspis (from *aspis*, "shield," whose form it resembled) by Dutch excavations conducted by W. Vollgraff.

In the Mycenaean or Late Bronze Age (*c.* 1650–*c.* 1125 B.C.) the city of Argos was eclipsed by Mycenae, Tiryns (*qq.v.*) and Midea, but with the collapse of the Mycenaean power and the infiltration of the Dorians in the late 12th century Argos became the dominant city-state of the Argolis and, during the tyranny of Pheidon (675?–655? B.C.), even of the whole Peloponnese. Later



FROM THE "ARGIVE HERAEUM"

PLAN OF THE ARGIVE HERAEUM

the Argives were frequently at war with the Spartans, who severely defeated them at Sepeia in 494 B.C. and who endeavoured to protect the older settlements such as Mycenae and Tiryns, both of which had sent detachments in 480 to fight the Persians when Argos itself had remained neutral. In revenge the Argives destroyed these cities in 462 B.C.

In 461 Argos made an alliance with the Athenians, who were shortly to capture Memphis in Egypt (where they had gone to assist Inaros, the Libyan king, against Persia), and Athens' old rival Aegina. In 451 Sparta signed a five-year truce with Athens and a 30-year one with Argos, which therefore remained neutral during the earlier part of the Peloponnesian War (*q.v.*). After the peace of Nicias in 421 B.C. the alliance between Athens and Argos, Mantinea and Elis was renewed, but the defeat of the Argives, Athenians and their other allies by the Spartan king Agis II at Mantinea in 418 B.C. was followed by an oligarchic revolution at Argos, which returned to its neutrality (repudiating the treaty with Athens and making a 50-year alliance with Sparta) and maintained it even after a democratic counterrevolution. Peace with Sparta, however, seemed unnatural to the Argives, and in 395 (when the Corinthian War began; *see* GREECE: *History*) they signed a federal union with Corinth. This union, however, was partly severed by the military operations of Agesilaus II, and the break was confirmed by the peace of Antalcidas (the King's peace) of 387 when Artaxerxes II of Persia dictated his terms to the Greeks. The rise of Thebes under Epaminondas was at first hailed joyfully by the Argive democrats, who took part in his two victories at Leuctra (371) and Mantinea (362) and violently repressed an attempted counterrevolution by the oligarchs. On the retirement of the Theban forces the Argives again suffered from the aggressions of Sparta and appealed to Philip II of Macedonia, who restored to them their old province of Cynouria on the western side of the gulf of Argos. Later the Argives came to recognize the danger from Macedonia, and in the Lamian War (323–322 B.C.) they joined the confederate forces against Antipater; Argos, however, was captured by Cassander in 317 and by Demetrius I Poliorcetes in 303 B.C. In 272 Sparta and Argos united to resist Pyrrhus, king of Epirus, who was killed during a night attack on the latter city. For several years Argos was subject to Antigonus II Gonatas, but in 229 it joined the Achaean league (*q.v.*) and remained an active member except for brief occupation of the city by the Spartan kings Cleomenes III (225) and Nabis (196).

The Roman conquest and the destruction of Corinth in 146 B.C. increased the relative importance of Argos, which became the centre of the Achaean league. The city was temporarily captured by the Goths in A.D. 267 and in 395, but it continued to be important in Byzantine times. After the establishment of the Frankish principality of Achaea after the fourth crusade (1202–04), Argos declined and Nauplia became the capital of the Argolis; it is now the capital of the modern *nomos* of Argolis. In 1397 Argos was captured by the Turks, who took it again in 1500, when they massacred the inhabitants and replaced them with Albanians. Argos figured in the Greek War of Independence (*see* GREEK INDEPENDENCE, WAR OF); there Demetrios Ypsilantes summoned the first free Greek parliament in 1821, and in 1825 the plain of Argos was ravaged by Ibrahim Pasha.

Archaeology.—The French School at Athens conducted various excavations at Argos before and after World War II, uncovering part of the prehistoric city of the Aspis and the remains of a temple of Apollo of the Saddle on the neck dividing that hill from the summit of Larissa. On the lower ground their researches uncovered another temple site, as well as the site of what was in all probability the *bouleuterion* (council house) of the Greek city, city baths and a *heroon* (hero-cult shrine) of Roman date, and a cemetery with graves extending from the Middle Helladic period (*c.* 2000–*c.* 1600 B.C.) to late Roman times.

The Argive Heraeum, the centre of the worship of the mother goddess Hera, the national sanctuary of the Argolis long before the coming of the Dorians, was traditionally reported to have been founded by Phoroneus. The prehistoric settlement on the upper terrace, excavated by an American expedition under C. W. Blegen, has been tentatively identified with the legendary Prosymna; it lasted from the Neolithic period to about 1100 B.C. A *tholos* (domed or beehive) tomb in the vicinity dates from the second half of the 15th century B.C. The town site was abandoned but the worship of the Mycenaean goddess continued on the upper terrace, which was bounded on the west by a Cyclopean terrace wall. Some idea of the earliest post-Mycenaean temple may be gained from a terra-cotta model of late geometric date (*c.* 8th century) found on the site (even if this is regarded as the model of a house), showing a single-roomed building with high gable roof and a porch of two wide-set wooden columns. A more monumental temple was erected later, probably in the 7th century B.C. Nothing survives of this except the limestone platform and a portion of the stylobate, but the weathering on the latter fragment and the measurements suggest that the temple may have had 6 by 14 wooden columns 31.496 in. in diameter with an intercolumniation of approximately 97 in. The ruins of this temple were still visible when it was visited by Pausanias, who records that it was burned down in 423 B.C. owing to the negligence of its priestess, Chryseis, who fled to Tegea but whose statue still stood in front of the ruins. A base of irregular stones 70.88 in. square marks the site of the cult statue.

Construction of a new and more splendid temple was begun immediately by the local architect Eupolemos, who designed an ideal structure in limestone with 6 by 12 Doric columns, column spacings of exactly 10, diameters of 4, triglyphs of 2 and metopes of 3 Doric feet and so on (the Doric foot was 12⅞ in.). It was in this temple that Pheidon of Argos dedicated offerings of the ingot currency of spits which were current before the first issue of Aeginetan silver money.

A famous school of sculptors and bronze workers existed in

Argos, presided over by Ageladas, who was said to have taught both Phidias and the Argive Polyclitus the elder. The latter was chosen to execute the cult statue at the Heraeum, a colossal figure of Hera in gold and ivory, enthroned and bearing in her left hand a sceptre surmounted by a cuckoo (for Zeus had wooed her in the form of that bird). Polyclitus also wrote a treatise on the art of modeling and illustrated his theories on the ideal statue by the representation of a boy carrying a lance (the so-called Doryphoros or "lance-bearer") of which many Roman copies survive. No certain copy exists of Argive Hera, but an idea of the head may be gained from certain Argive coins of the same period as the statue. The marble head found by the American school may represent Hera but was certainly no copy of the gold and ivory statue.

ARGOSTOLION, the capital of the *nomos* (department) of Cephalonia (Kephallēnia or Kefallinia), one of the Ionian islands, Greece, is the seat of a bishop of the Greek church. Pop. (1961) 7,322. It was founded by the Venetians in 1757 to replace the medieval capital of St. George; but there is a Mycenaean necropolis at Mazaracata and there are ancient fortifications at Cranii nearby. Argostolion has a good harbour, with a quay a mile in length. Shipbuilding and silk-spinning are carried on. West of the harbour a curious stream, flowing *from* the sea, is employed to drive mills before losing itself in caverns inland. The town was devastated by an earthquake in 1953. *See* also Cephalonia; Ionian Islands.

(D. M. N.)

ARGOSY, the term originally for a carrack or merchant ship from Ragusa and other Adriatic ports, later used poetically of any vessel carrying rich merchandise. In English writings of the 16th century the seaport named is variously spelled Ragusa, Aragouse or Aragosa, and ships coming thence were named ragusyes, arguzes and argosies, the last form surviving and passing into literature. The incorrect derivation from Jason's ship, the "Argo," is of modern origin.

ARGUIN, an island (identified by some writers with the Cerne of the Carthaginian navigator, Hanno), off the west coast of Africa, about 50 mi. S.E. of Cap Blanc, in 20° 35′ N., 16° 25′ W. It is about 4 mi. long by 2½ mi. broad, produces gum arabic and is the seat of a turtle fishery. Off the island, which was discovered by the Portuguese in the 15th century, are extensive and dangerous reefs. Arguin was occupied in turn by the Portuguese, Dutch, English and French. It became part of Islamic Republic of Mauritania in 1960. Aridity and bad anchorage prevent permanent settlement.

(J. D.)

ARGUS, the name of three figures in Greek mythology.

1. Argus, the son of Inachus, Agenor or Arestor, or, according to others, an earthborn hero (*autochthon*). Because of the number of eyes in his head or all over his body, he was called Panoptes (all-seeing). He was appointed by Hera to watch the cow into which Io (*q.v.*) had been transformed but was slain by Hermes who stoned him to death, or put him to sleep by playing on the flute and then cut off his head. His eyes were transferred by Hera to the tail of the peacock. This Argus was often confused with the son of Niobe who gave his name to the city Argos (Aeschylus, *Prometheus Vinctus*; Ovid, *Metamorphoses*).

2. Argus, the old dog of Odysseus who recognized his master returning to Ithaca in disguise after 19 years, and promptly expired (Homer, *Odyssey*).

3. Argus, the architect of the ship "Argo" (*see* Argonauts).

(T. V. B.)

ARGYLL, EARLS AND DUKES OF. For the rise of this family of Scottish peers, originally the Campbells of Lochow, and first ennobled under the title of Lord Campbell, *see* Argyll. The 1st earl of Argyll, Colin, Lord Campbell (d. 1493), received his title in 1457. His son, Archibald, the 2nd earl, was killed at the battle of Flodden in 1513; the 3rd and 4th earls were Archibald's son Colin (d. 1529) and grandson Archibald (d. 1558).

Archibald Campbell (*c.* 1532–73), 5th earl of Argyll, succeeded his father in 1558. He was an adherent of John Knox and assisted Lord James Stewart (afterward the regent Moray) in the warfare of the lords of the congregation against the regent Mary of Lorraine, the mother of Mary Stewart. Argyll's support of Mary Stewart after her return to Scotland (1561) gradually separated him from John Knox's party. When Mary escaped from Lochleven castle in 1568, he commanded her forces during the few days which preceded her flight to England. He then made his peace with Moray, although he may have connived at his murder in 1570. He became lord high chancellor of Scotland in 1572 and died on Sept. 12, 1573. His first wife was an illegitimate daughter of James V, and he was thus half brother-in-law to Mary and Moray.

Archibald Campbell (1607–61), 1st marquess and 8th earl of Argyll, eldest son of Archibald (1575–1638), 7th earl, took over the management of the family estates in 1619 after his father had renounced Protestantism. As Lord Lorne (the title borne by the eldest son of an earl of Argyll) he was made a privy councilor in 1628, but his refusal to support the attempt by Charles I to enforce the use of a new liturgy in Scotland brought him into disfavour, and by a secret commission the earl of Antrim was permitted to invade Argyllshire. The expedition was unsuccessful, but it strengthened the determination of Argyll (who inherited the title by the death of his father in 1638) to join the Covenanters in defense of Presbyterianism. He wrote to Archbishop Laud in 1639, defending the abolition of episcopacy by the general assembly, which had continued to sit after its dissolution by Hamilton, the king's commissioner. His increasing opposition to the royal policy brought him gradually into conflict with the earl of Montrose and his associates, but their plot to discredit Argyll on the occasion of Charles's visit to Scotland in 1641 miscarried, and they were themselves imprisoned. Charles was obliged to make concessions to the Covenanters; he acquiesced in the transfer of judicial and political appointments to the parliament, and he created Argyll a marquess (1641) with a pension of £1,000 a year. During the next two years Argyll was mainly responsible for maintaining unity among the Scottish Presbyterians and for effecting the alliance with the English parliament (1643). He was made a member of the committee of both kingdoms and his active participation in the English Civil War began in Jan. 1644: he commanded a troop of horse when the Scottish army invaded England. But he was soon compelled to return in order to oppose royalist movements in the north and to defend his own territories against attack by the marquess of Huntly. During the summer of 1644 he fought inconclusively against Irish troops commanded by Montrose, but soon abandoned his commission, retiring to Inveraray castle. Montrose unexpectedly followed him there in December, forcing him to flee to Roseneath (Dumbartonshire) and devastating his territories. Argyll was surprised and defeated by Montrose at Inverlochy on Feb. 2, 1645, and again at Kilsyth on Aug. 15; but he was present when Montrose himself was finally beaten at Philiphaugh on Sept. 13.

Up to this point Argyll's statesmanship had been highly successful. Charles I became a prisoner and the national liberties and religion of Scotland had been defended and seemed to be further secured by the alliance with the triumphant parliament and army of England. But Argyll's whole policy depended on the maintenance of this alliance and he opposed vigorously but vainly the secret treaty concluded between the king and the Scots against the English parliament (the Engagement) in July 1648. The duke of Hamilton, marching to oppose Cromwell's advance in accordance with the new treaty, was defeated by him at Preston; but Argyll joined the extreme Covenanters in Edinburgh and established a new government which welcomed Cromwell on Oct. 4, 1648. This alignment was destroyed, however, by Scottish disapproval of the execution of Charles I (Jan. 1649) and Argyll supported the in-

vitation from the Covenanters which resulted in the arrival in Scotland (1650) of Prince Charles whom he himself crowned king of Scotland, as Charles II, at Scone on Jan. 1, 1651. He strongly opposed but was unable to prevent the expedition to England which resulted in Charles's defeat at Worcester (Sept. 3, 1651). In the subsequent reduction of Scotland, after holding out in Inveraray castle for nearly a year, he was at last surprised in Aug. 1652 and submitted to the Commonwealth. In Richard Cromwell's parliament of 1659 Argyll sat as member for Aberdeenshire. At the Restoration he presented himself at court, but was at once arrested by order of Charles II, and in Dec. 1660 was sent to Edinburgh to stand his trial for high treason. He was acquitted of complicity in the death of Charles I and his escape from the whole charge seemed imminent. But the arrival of a packet of letters written by Argyll to George Monck (commander in chief in Scotland from 1654 to 1660) showed conclusively his collaboration with Cromwell's government, particularly in the suppression of the earl of Glencairn's royalist rising of 1653–54. He was immediately sentenced to death and was beheaded at Edinburgh on May 27, 1661.

Bibliography.—J. Willcock, *The Great Marquess: Life and Times of Archibald, 8th Earl . . . of Argyll* (1903); S. R. Gardiner (ed.), *Charles II and Scotland in 1650* (1894); C. M. Firth (ed.), *Scotland and the Commonwealth* (1895); C. S. Terry (ed.), *The Cromwellian Union* (1902).

Archibald Campbell (1629–85), 9th earl of Argyll, eldest son of the 8th earl, was born on Feb. 26, 1629 at Dalkeith. He studied abroad, but returned to Scotland in 1649. He fought at Dunbar (Sept. 3, 1650) and, after the battle of Worcester, joined the royalist leader Glencairn in the Highlands. Ultimately he fell foul of both the royalists and their opponents; he was imprisoned in 1657 for refusing to renounce allegiance to the Stewarts and again in 1661 for incautious criticisms of the government of Charles II. He was released in 1663 and his father's earldom and lands were restored to him. However, his staunch Protestantism and great territorial influence made him suspect to James, duke of York, who became high commissioner in Scotland in 1680. He was sentenced to death on a dubious charge of high treason in 1681, but escaped to Holland and there joined the conspiracy to procure the succession of the duke of Monmouth. He led an unsuccessful invasion of Scotland in 1685, was captured at Inchinnan on the river Clyde on June 18 and was beheaded at Edinburgh on June 30.

See J. Maidment (ed.), *The Argyle Papers* (1834); J. Willcock, *A Scots Earl in Covenanting Times* (1907).

Archibald Campbell (1651?–1703), 10th earl and 1st duke of Argyll, was the eldest son of the 9th earl. Failing to obtain a reversal of his father's attainder, he went to The Hague and joined William of Orange. Despite the attainder he was admitted in 1689 to the convention of the Scottish estates and in June of that year an act was passed restoring his title and lands. He raised the earl of Argyll's regiment of foot, which served in the British army from 1692 to 1697, and was created duke of Argyll in 1701. He died on Sept. 25, 1703, at Cherton house near Newcastle.

John Campbell (1680–1743), 2nd duke of Argyll, son of the 1st duke of Argyll, was born at Petersham, Surrey, on Oct. 10, 1680. In return for his services in furthering the union of England and Scotland he was created a peer of England (1705), with the titles earl of Greenwich and baron of Chatham. He served under the duke of Marlborough from 1706 in the war of the Spanish Succession, gaining particular distinction at the battle of Malplaquet in 1709. He acted as commander in chief in Spain and as ambassador to the archduke Charles in 1711. Argyll's intervention at Queen Anne's last council meeting helped to ensure the Hanoverian succession (Aug. 1714) and during the early years of George I's reign he stood in high favour at court. As commander in chief of the forces in north Britain during the Jacobite rebellion of 1715, he managed with very little bloodshed to suppress the rising in Scotland. After a temporary eclipse, caused by disagreement with the ministry rather than the disfavour of the king, he regained his influence and was created duke of Greenwich (1719). He held various offices and in 1736 was made a field marshal. He strenuously opposed in 1737 the bill to penalize the city of Edinburgh over the Porteous riots, and a violent speech against the government in April 1740 led again to his dismissal from office. Apart from one further short period of power, he spent the remainder of his life in retirement, dying at Petersham on Oct. 4, 1743.

Archibald Campbell (1682–1761), 3rd duke of Argyll, brother of the 2nd duke, was born at Ham house, Surrey, in June 1682. He served for a short time under the duke of Marlborough, but was appointed treasurer of Scotland in 1705 and the following year was one of the commissioners for negotiating the union of the two kingdoms. Raised to the peerage of Scotland as earl of Islay he was among the 16 Scottish peers chosen to sit in the first parliament of Great Britain. He became a privy councilor in 1711, keeper of the privy seal of Scotland in 1721 and keeper of the great seal of Scotland in 1733. He played an important part in the movement led by Duncan Forbes of Culloden to promote Scottish loyalty to the Hanoverians by raising Highland regiments from among the Whig clans. Succeeding his brother as duke of Argyll in 1743, he rebuilt Inveraray castle and collected one of the most valuable private libraries in Great Britain. He died in London on April 15, 1761, without legitimate issue.

The succession thus passed to the descendants of the younger son of the 9th earl, the Campbells of Mamore. The 4th duke, John (*c.* 1693–1770), was succeeded by his son John (1723–1806), the 5th duke, who had represented Glasgow in the house of commons from 1744 to 1761, and Dover from 1765 to 1766, when he was created a peer of Great Britain as Baron Sundridge, the title by which until 1892 the dukes of Argyll sat in the house of lords. His sons George (1768–1839) and John (1777–1847) became in turn the 6th and 7th dukes.

George Douglas Campbell (1823–1900), 8th duke of Argyll, the second son of the 7th duke, was born at Ardencaple castle, Dumbartonshire, on April 30, 1823. He became a prominent Liberal member of the house of lords, and was lord privy seal (1852) and postmaster general (1855) in the cabinets of Lord Aberdeen and Lord Palmerston. As secretary of state for India in Gladstone's first ministry (1868–74), he was responsible, against the advice of the Indian administration, for the refusal of help to the amir of Afghanistan, which caused the amir to approach Russia and led later to the second Afghan War. His disapproval of Gladstone's second Irish Land act (1881) caused him to resign the office of lord privy seal to which he had been appointed in 1880; later he opposed the Home Rule bills with equal vigour. Detached from party politics, Argyll wrote many letters to *The Times* on questions which included the rights of landowners; he himself was a keen and enlightened landlord, and much interest still attaches to his *Scotland as It Was and as It Is* (1887). One of the duke's chief preoccupations was the reconciliation of the dogma of Christianity with the progress of scientific discovery. His *The Reign of Law* (1866), *Primeval Man* (1869), *The Unity of Nature* (1884), *The Unseen Foundations of Society* (1893) and other essays found a wide public. He also wrote on the eastern question with particular reference to India, on the history and antiquities of Iona, and on patronage in the Church of Scotland. Argyll, to whose Scottish title a dukedom of the United Kingdom was added in 1892, died at Inveraray on April 24, 1900; his *Autobiography and Memoirs* was published posthumously by his widow (1906).

John Douglas Sutherland Campbell (1845–1914), 9th duke of Argyll, eldest son of the 8th duke, was born at Stafford house, Westminster, on Aug. 6, 1845. His marriage in 1871 to Princess Louise, daughter of Queen Victoria, gave him a special prominence in British public life. He was governor general of Canada from 1878 to 1883, and Unionist member of parliament for South Manchester from 1895 to 1900. His reminiscences, *Pages from the Past*, were published in 1907. He died in the Isle of Wight on May 2, 1914, and was succeeded by his nephew Niall Diarmid Campbell (1872–1949), 10th duke; he in turn was succeeded by his cousin, Ian Douglas Campbell (1903–), 11th duke.

(G. S. P.)

ARGYLL, a county on the west coast of Scotland, is second in size only to Inverness-shire, which adjoins it to the north. It is bounded on the east by Perthshire and Dumbartonshire, on the west by the Atlantic and on the south by the Firth of Clyde with

its tributaries, while the Mull of Kintyre is separated from Ireland by the North channel, only 13 mi. wide. One-quarter of the county consists of islands, including the large islands of Mull, Jura and Islay, smaller ones such as Tiree, Colonsay, Iona, Staffa (*qq.v.*), Coll and Scarba (the latter separated from Jura by the notorious whirlpool of Corrievreckan), together with many tiny islets that are little more than rocks. The total land area is 3,110 sq.mi.

The boundaries of Argyll have varied at different times, and it has been (1) a small independent kingdom known as Dalriada; (2) a spacious province made up of north and south Argyll, stretching from Loch Broom to the Mull of Kintyre; and (3) an extensive county composed of the old shires of Argyll and Tarbert formally united in 1633. Argyll (Gaelic *Earraghaidheal* meaning "coastland of the Gael") has finally superseded the old alternative form of Argyle.

Physical Features.—Argyll comprises about one-third of the wet, deeply dissected western Highlands, whose rivers flow to the Atlantic. There is a repeated pattern of plateau blocks, sometimes roughly rhomboidal and bounded by valleys which have some correspondence to major fault lines. Thus the great Glen fault corresponds with the southwest-northeast line of the Firth of Lorne and Loch Linnhe, at the head of which Loch Eil runs due west at an acute angle. The Caledonian trend southwest-northeast is of particular importance in the grain of the country. The plateau blocks, at various dominant heights from 1,000 ft. to 3,000 ft., were dissected by water and ice to yield very spectacular scenery, particularly in the higher parts of the north and east, where residual heights such as Bidean nam Beann (3,766 ft.) and Ben Cruachan (3,689 ft.) rise above the general summit plane. Glacial action has gouged the corries and rock basins of freshwater lochs such as Awe (*q.v.*) and Avich, and of sea lochs like Fyne and Long, and deposited many hummocks of coarse moraine or boulder clay on lower ground. Postglacial drowning, in an area of local depression of the crust through the weight of the ice cap, has given the long, complex coastline of peninsulas and sea lochs, while later partial recovery of the land has left raised beaches in sheltered coastal reaches at about 25 ft. and about 100 ft. above mean sea level.

The solid rocks of Argyll include: the Dalradian and Moine schists (mainly mica-schists, slates and phyllites), with contemporary granites like those at Strontian, limestones as in Lismore Island and quartzites giving conical hills such as the Paps of Jura; the granites (Glen Etive), the andesite and rhyolite lavas (Glen Coe and Oban areas) and associated dikes of the Old Red Sandstone era; the downfaulted Carboniferous area between Campbeltown and Machrihanish, including some coal; the small patches of Mesozoic, Lias shales and Greensand (including the white sandstones of Lochaline) in the north; and the Tertiary cauldron-subsidence and associated basalt lavas and dolerite dikes of Mull and adjacent mainland areas.

Coastal Argyll has a cool, damp summer, a mild, wet winter with little snow and a drier, rather sunny late spring and early summer (July mean approximately 58° F.; January mean about 40° F.; mean annual rainfall in windward sites less than 40 in.). Inland conditions are much wetter (mean rainfall commonly exceeding 80 in.) and a little less equable, with from 10 to 30 days of snow on the hills and severe frosts in sheltered hollows.

Residuals of natural vegetation include: the valley oak woods, near their limit and tending to be on the sunny side; birch or pine on shady or higher sites (birch, for instance, regenerating naturally to 1,000 ft. or more if protected from grazing); hazel scrub in the lava country of Mull; a moorland flora varying with grazing and rather tolerant of wet conditions, with much reed and purple moor grass, though heather and mat grass and wild flowers such as harebells are also found; and small areas of Alpine flora including purple saxifrage.

Animals of inland Argyll include red deer, red squirrels, pine martens, wildcats, mountain hares, golden eagles, capercaillies and ptarmigan, with many badgers in the oak woods. Foxes, largely deprived of their natural diet of rabbits through myxomatosis, were frequently reported raiding poultry. Despite an overlap, the coastal tracts and islands may rather be associated with such fauna as gray seals, fulmar, petrels and (particularly on Tiree) migrating ducks and waders.

The fine Glen Coe motor road traverses the wild sad country associated with the massacre of 1692, while Sunart and Morar have fine mountain and coast scenery. In the southeast is the Argyll National forest park, including the mountain range popularly known as Argyll's bowling green between Loch Goil and Loch Long.

(A. T. A. L.)

History.—The secular and the religious history of Argyll are closely connected. The recorded secular history begins in the 2nd century A.D. when Argyll was invaded by Scots (Celts) who came from Ireland, then known as Scotia. The earliest Celtic settlement is assigned to the 3rd century when a victorious chief, Cairbre Riada, occupied lands in the area later known as mid Argyll. These lands, called Dalriada (*q.v.*), were reinforced from time to time by fresh bands of immigrants from Celtic Ireland. Dalriada developed gradually as an independent kingdom under ambitious rulers and maintained a separate existence until 844 when one of them, Kenneth Macalpine, united the men of Dalriada with the Picts of central Scotland and founded a new hybrid kingdom from which Scotland ultimately emerged. After Kenneth's departure from Argyll the Norsemen obtained control and held sway until 1266 when Argyll was added to the Scottish kingdom. Prior to this, however, semi-independent chiefs of mixed Celtic and Norse ancestry acquired power in Argyll and the Isles. One of them, Somerled, really the first lord of the Isles, was killed near Renfrew in 1164 on an expedition against the Scottish king, but the lordship of the Isles was held by his descendants until 1493 when John, the last MacDonald lord of the Isles, was deprived of his vast estates by James IV. The Campbells of Lochow (now Lochawe) rose on the ruin of the MacDonalds and had a run of success unparalleled in Scottish history. The Campbell chiefs were men of much natural ability and the prominence of the 9 Campbell earls of Argyll in Scottish history and of the subsequent 11 dukes of Argyll in the history of Great Britain is unsurpassed by any other single noble British family.

The failure of the second Jacobite rising, in which the men of Argyll with few exceptions served under the Hanoverian banner, was followed by important political and economic changes. The abolition of the heritable jurisdictions in 1747, prior to which Highland lairds and chiefs had been petty kings over their tenants and followers, led to the development of new relationships. The rents of tenants became of greater importance to their masters than the former friendly loyalties. Sentimental ties were broken and the small farms and holdings which had supported large numbers of occupants on a meagre scale of subsistence had to give way to larger farms stocked with flocks of sheep, immediately but only temporarily more profitable to their owners. Throughout the Highlands, including Argyll, thousands of small tenants were displaced by methods that were later universally condemned.

The ecclesiastical history of Argyll shows a people deeply concerned with matters of religion. The earliest phase was the old Celtic period when missionaries from Celtic Ireland spread the Christian faith. St. Columba (*q.v.*) with his associates from Iona (*q.v.*) and successors did more for the spreading of the Gospel than any other contemporary group of religious pioneers in Britain. The Celtic phase lasted for several centuries until it was displaced by the Roman Catholic period which continued until the first Scottish Reformation (1560) in which the 5th and 6th Campbell earls played a decisive part as the most influential Protestant laymen in Scotland. The Protestantism of Scotland and of Argyll was never seriously challenged at any subsequent period although there were conflicts between Episcopacy and Presbyterianism. In the end the latter prevailed and is still the commonest form of church government in Argyll.

Population and Administration.—The population of Argyll in 1961 was 59,345. The peak figure for the county was 100,973 in 1831, after which every decennial census, except 1881, 1921 and 1951, recorded a decrease. The decline in population tended to be greater in rural areas than elsewhere but, even so, the rural population still represents more than half the total. There are six

small burghs of which those with the biggest population in 1961 were Dunoon (9,215), Campbeltown (6,523) (*qq.v.*) and Oban (6,869). The oldest burgh, Inveraray (*q.v.*), chartered in 1474, had only 501 inhabitants compared with 1,208 for Lochgilphead (*q.v.*) and 668 for Tobermory. In 1961, 9,510 people (16.0% of the population) spoke Gaelic as well as English.

The headquarters of the various branches of the county council are in different burghs. Those of the county clerk, the chief constable and the county engineer are at Lochgilphead; the director of education, the county architect and the county librarian are stationed in Dunoon; the county medical officer and the chief sanitary inspector have their offices in Oban; and the county treasurer and the county assessor have their headquarters at Campbeltown.

The coat-of-arms of the county council shows its historical associations with the clans of the MacDougalls, MacDonalds and Campbells, while its motto is in Gaelic: *Seas ar coir* ("Maintain our right").

Industries and Communications.—Industries include farming, afforestation, quarrying, the tourist trade and numerous occupations requiring only small numbers of workers. Farming, including sheep and cattle raising, is the staple industry, giving employment to more than 6,000 persons in the early 1960s. The forestry commissioners, with their extensive estates well-planted with trees, gave employment to more than 1,000 workers and their activities were still expanding. Only about 5% of the total land area is agriculturally improved land, of which just over half is arable land mainly for oats, hay and other fodder crops, the rest being permanent grass. The agriculture of Argyll is somewhat transitional in character. There are individual farms like those of the lowlands in the southeast, in much of Kintyre and on Islay, but there is more crofting agriculture, including common grazings, in the north of the county, though the crofts may be fairly substantial as on Tiree. Both farms and crofts depend on rough grazings on the hills for sheep and cattle, and on winter pasture on the lower slopes, with the fodder from the improved pastures and arable to provide additional winter feed.

The only colliery in active production is at Machrihanish, where several hundred workers have a weekly output of about 3,000 tons. Small veins of silver were exploited at Silvercraigs near Lochgilphead in the 19th century and copper used to be worked in various localities. Lead was also produced in many areas, especially near Strontian, where the mineral strontianite containing the element strontium was found. The abundance of slate in different parts of Lorn supported many quarrymen at such places as Easdale, Luing and Ballachulish, but there are signs that the slate industry has passed its peak. A fine quality sand for making optical glass is produced at Lochaline.

At one time herring fishing was a major occupation but it languished and although many fishermen turned their attention to whitefish their number fell from 1,222 in 1921 to 807 in 1951. The tourist trade provides valuable additions to local incomes, but the county's chief hope lies in the introduction of a multiplicity of small industries such as the manufacture of chipwood and paper pulp, pit props and fence posts from the abundance of local timber. In the 1950s a clothing factory was established at Campbeltown and pottery factories for high-class articles were set up in Strachur and Dunoon.

The fresh-water lochs are used to supply both domestic water and electric power.

The county was slow in introducing railways and it was not until 1880 that Oban was linked with Glasgow by the extension of the existing line from Callander. Later came the construction of the branch line from Connel ferry to Ballachulish but this line was never continued to Kinlochleven, the chief industrial village in Argyll. Much transport still goes on by sea between Argyll ports and outside communities. The roads extend to 1,450 mi. and vary in quality from excellent to poor but the main roads in general are good. Much was hoped for in the early 1960s from the development of existing and projected air services to Tiree, Mull, Islay and other islands as well as to mainland airports; and it was thought that helicopters might be used to link isolated communities with airports of national importance. (C. M. M.)

ARGYRODITE, the silver sulfide mineral in which the element germanium was discovered (*see* Germanium). First discovered in the form of crystalline crusts in a silver mine at Freiberg, Saxony, it was later found in the form of large distinct crystals in Bolivia.

A relatively scarce mineral, it occurs associated with the tin ore cassiterite, the iron ore siderite and with silver sulfosalts in sulfide veins. It is opaque, with a metallic lustre; the colour is black with a purplish tinge. The hardness is 2.5, specific gravity 6.3. Argyrodite is isometric in crystallization. Named after its silver content, its formula is Ag_8GeS_6. The corresponding tin compound, Ag_8SnS_6, is known by the name canfieldite, and a complete solid solution series extends between this species and argyrodite. (Cl. F.)

ARGYROPULUS (Argyropoulos), **JOHN** (1415–1487), Byzantine humanist, an active promoter of the revival of learning in the west, was born in Constantinople and became a teacher there. Among his pupils was the scholar Constantine Lascaris (*q.v.*). He divided his time between Italy and Constantinople. He was in Italy for the council of Florence (1439) and also spent some time teaching in Padua. When Constantinople fell in 1453 he left it for the Peloponnesus and then in 1456 took refuge in Italy. He was professor of Greek in Florence, and in 1471 moved to Rome where he continued to teach Greek until his death on June 26, 1487. His pupils in Italy included Politian and Johann Reuchlin (*qq.v.*). He left Latin translations of a number of Aristotle's works, some letters in Greek and Latin and some Greek orations. His real importance lies in his work as a teacher in Italy rather than in his writings.

See S. P. Lampros, *Argyropouleia* (1910) for his minor works. See also G. Cammelli, *I dotti bisantini e le origini dell' umanesimo*, vol. 2, *Giovanni Argiropulo* (1941). (J. M. Hy.)

ARIA, a solo song, either simple or elaborate, with instrumental accompaniment, that is not only one of the most important ingredients of opera, especially up to the later 19th century, but is also found extensively outside opera in the 17th and 18th centuries, notably in cantatas and oratorios (*qq.v.*).

The term originated in Italy in the 16th century and first gained currency with the publication in 1602 of *Le Nuove Musiche*, a collection of solo songs with *continuo*, by Giulio Caccini, who called the strophic songs in his collection *arie*. The word can be seen as a counterpart to the contemporary English "ayre" and French *air* (*see* Air); it was later adopted in Germany, where the songs of composers such as Heinrich Albert and Adam and Johann P. Krieger are called *Arien*. All the more serious strophic songs composed thereafter in Italy—and there were a great many of them—were called arias; the form soon made its way into opera (*e.g.*, Orpheus' "Vi ricord', o boschi ombrosi" in Monteverdi's *Orfeo*, 1607). Instead of using the same music for every verse some composers varied a basic vocal line over a constant, steadily moving bass. Terms such as *canzonetta* and, later, *arietta* were used for arias of more popular or frivolous cast.

After about 1620 arias, still usually found as separate songs in published collections, were nearly always in triple time and became longer, notably at the hands of the Venetian organist Giovanni Pietro Berti; and new structural schemes, often suggested by the texts, were devised to lend unity to what might otherwise have become a somewhat sprawling form. It was Berti who composed a song, "Dove sei gita," published in 1634, that is probably the earliest aria in *da capo* form; this involved the organization of an aria as a whole and not merely that of a single verse whose music was then used for subsequent verses. (Berti achieved the new ABA form in the space of a single verse by placing a triple-time refrain at the beginning as well as at the end, the main body of the text being set in a contrasting duple time between them.)

For over a century the *da capo* aria, now mainly found in Italian operas and cantatas, was one of the most popular musical forms of all time. Texts became much shorter, since, instead of having several verses sung to the same music, all that was required was, first, a few lines, heard twice complete in the outer A sections to the same music, which treated the words expansively with plenty of repetition, and, secondly, a few more lines for the central B section, which was usually much terser and in a related key and frequently contrasted in mood and tempo. Instrumental ritornellos (sometimes sharing the vocal material) framed the arias, and snatches of them often punctuated the vocal sections. While the story of an opera was advanced through recitative, the arias were dramatically static, affording opportunities for single characters to reflect on the immediately preceding action, after which they left the stage. Arias might assume various moods and were codified as *Aria cantabile, Aria di bravura, Aria parlante* and so on; these were supposed to be carefully distributed throughout an opera or single act, though in fact their finest composers—among whom Alessandro Scarlatti and, especially, Handel stand pre-eminent—did not rigidly observe these conventions. The finest singers of these arias, particularly sopranos, both female and male (*castrati*), were the most popular international public entertainers of the age and decorated the reprise of the A section of an aria with brilliant improvised embellishments (sometimes in competition with an equally brilliant and agile obbligato instrument, such as flute or trumpet), culminating in an unaccompanied cadenza at the final cadence. The *da capo* aria was also a staple constituent of chamber cantatas and to a lesser extent of sacred cantatas (many of Bach's, for example) and oratorios (the finest examples being by Handel). Composers occasionally dispensed with the *da capo* form for dramatic effect.

By about the third quarter of the 18th century influential voices—those of Jean Jacques Rousseau, Francesco Algarotti and C. W. Gluck, for instance—began to protest against the *da capo* aria, and it suffered a sharp decline. These writers protested against abuses such as excessive coloratura; the dramatic impropriety of a return to the mood of section A after this mood had been dispelled by the sense of section B; and the "absurdity" of a character who had sworn, say, "immediate vengeance" in a recitative, having to wait before elaborating his point in the ensuing aria while the orchestra played a ritornello. It is tempting to attend to these admittedly reasonable complaints and to forget that in its long heyday the *da capo* aria gave immense pleasure. A reaction against it was bound to come. When baroque opera began to return to the operatic stage about the middle of the 20th century, it was seen that in the hands of an imaginative producer and musical director, unshackled by virtuoso singers, long successions of recitative and aria need not lead to dramatic absurdity or stagnation.

There is less to say about the aria after about 1770. It continued to play a prominent part in opera in many different, less stereotyped forms, ranging from simple strophic songs to long and elaborate *scenas*. Since Gluck was impatient of the *da capo* aria and he was the greatest operatic composer between Handel and Mozart it is not surprising that his operas are the first important ones to show this new variety. In the late 18th century the aria enjoyed a vogue as a concert piece (Mozart). At this time, too, many arias were in two distinct parts, one dramatic, one lyrical (e.g., Leporello's "Catalogue Aria" in Mozart's *Don Giovanni*). In Italian operas—those, for instance, of Donizetti and Verdi (up to *Aida*, produced in 1871)—the aria was cultivated over a longer period than in German operas. This was due not merely to the Italian love of singing but also to the operatic reforms of Wagner, which led to a "continuous" texture founded on orchestral motives in place of the discontinuous texture of separate numbers (aria, chorus, etc.), which, however, survive in special instances like the "Prize Song" in *Die Meistersinger von Nürnberg*, produced in 1868. In the 20th century arias occur mainly in operas by composers uninfluenced by, or hostile to, Wagner (*e.g.*, Stravinsky's *The Rake's Progress*, and the operas of Benjamin Britten). (*See* also OPERA and articles on individual composers.)

The term "aria" has also occasionally been used to denote instrumental pieces of a songlike nature (*e.g.*, the two middle movements of Stravinsky's Violin Concerto). (N. Fo.)

ARIADNE, a heroine of Greek mythology, daughter of Pasiphae and the Cretan king Minos. She fell in love with the Athenian hero Theseus, and with a thread or glittering jewels she helped him escape the Labyrinth after he slew the Minotaur (*q.v.*). Here the legends diverge: she was abandoned and hanged herself; she was carried to Naxos and left there to die or to marry Dionysus; she died in childbirth on Cyprus. Poetry and art preferred the picture of her asleep on the shore of Naxos while Dionysus gazes in admiration and love; and the Naxians, to oblige the view that she died, spoke of another and younger Ariadne. The jewels that guided Theseus through the Labyrinth became the stars in the constellation Corona, according to some.

Ariadne was once a vegetation-goddess of pre-Greek Minoan Crete, Cyprus, Naxos and perhaps elsewhere. The Naxians, who alone preserved her divinity, honoured the elder Ariadne, wife of Dionysus, with a joyous festival and the younger with gloomy sacrificial rites. Originally there must have been but one Ariadne, and these rituals reflected the death and revival of the vegetation she personified. Later Dionysus partly absorbed her cult, in one version (Odyssey, xi, *322*) even instigating her death. The myths say that Theseus "carried her off," as Paris did Helen, which may express the feeling that to pick the harvest fruit was to violate the plant's vital spirit. The goddess of the Minoan tree cult was apparently hanged in effigy on a tree, and Ariadne's hanging may go back to this (*see* also ARTEMIS; HELEN). She was honoured with dances, a common Minoan religious feature, whose motions and rhythms suggested the twistings of the Labyrinth. The myth that she died in childbirth on Cyprus arose from her role in the cult of Aphrodite, a role hard to assess because her name here may have been originally merely an epithet of Aphrodite, meaning "very holy" (Gr. *ari-*, *hagne*). Elsewhere, however, she was an individual, and indeed an original product of Minoan religious thought, since in comparable religions the dying vegetation is ordinarily thought of as male (*e.g.*, Attis and Adonis).

See Martin P. Nilsson, *Minoan-Mycenaean Religion*, 2nd ed. (1950), with references. (W. M. SE.)

ARIANISM is the belief, first propounded early in the 4th century by Arius (*q.v.*), that Christ is not truly divine, but a creature *ex nihilo*, who at one time did not exist. The controversy initiated by this teaching persisted until the 7th century.

The fundamental premiss of Arius was the uniqueness of God, who is alone self-existent and immutable. Because the Godhead is unique, it cannot be shared or communicated, so that the Son cannot be God. Because the Godhead is self-existent, the Son, who is not self-existent, cannot be God. Because the Godhead is immutable, the Son, who is mutable, being represented in the gospels as subject to growth and change, cannot be God. "He too is called God in name only"; *i.e.*, as a courtesy title. The Son must therefore be deemed a creature who has been called into existence out of nothing and has had a beginning—"there was when he was not." Consequently the Son can have no direct knowledge of the Father, being finite and of a different order of existence.

Arianism was the full flowering of the subordinatism that had been introduced into Christian theology in the 2nd century through the acceptance of the Logos or Word Christology, which tended to make the Son an impersonal function of and therefore inferior to the Father. Deriving his ideas possibly in part from Lucian (*q.v.*) of Antioch, Arius regarded himself as doing no more than carrying on the tradition exemplified by Dionysius of Alexandria and Origen (*qq.v.*). The latter was responsible for some very emphatic statements regarding the subordination of the Son, but whereas he balanced such ideas with his doctrine of the eternal generation, Arius seized upon the subordinationist elements alone and carried them to their logical conclusion.

Such teaching, as its opponents were not slow to point out, reduced the Son to a demigod, reintroduced polytheism (for the worship of the Son was not abandoned) and undermined the Christian concept of redemption, since only he who was truly God could be deemed to have reconciled man to the Godhead.

The controversy seemed to have been brought to an end by the

Council of Nicaea (A.D. 325; *see* COUNCIL), which condemned Arius and his teaching and issued a creed to safeguard orthodox belief. This creed states that the Son is *homoousion to patri* ("of one substance [or stuff] with the Father"), thus declaring him to be all that the Father is: he is completely divine. In fact, however, this was only the beginning of a long-protracted dispute, the intensity and duration of which were due to conservatism on the part of many who failed to appreciate what was at stake; to the readiness of many half-converted pagans to accept this rationalized brand of Christian belief; and to political intrigue and the entrance of the emperors into church affairs.

Arianism in the Empire After Nicaea.—The first stage, which centred in persons, lasted from 325 to 337 when Constantine I died. During this period the Arian leaders, exiled after Nicaea, sought by intrigue to engineer their own recall and then the banishment of their enemies. So in 328 Eusebius of Nicomedia was reinstated, although Arius himself had to wait a further seven years. Also in 328 Eustathius of Antioch, a prominent Nicene, was ousted, followed shortly by Marcellus of Ancyra; and in 336 after numerous *démarches* culminating in the synod of Tyre (335), Athanasius (*q.v.*) was exiled to Trier.

The second stage embraced the period of the joint rule (to 350) of Constans in the west and Constantius in the east, the latter being sympathetic toward the Arians and the former to the Nicenes. The Arian policy was now to have the Nicene statement replaced by another formulary, omitting the *homoousion* and so deposing it from its position as an ecumenical test; in this the Arians were at one with the general body of eastern opinion, which was essentially conservative and, while accepting the Nicene repudiation of Arianism, disliked the term because it was unscriptural. So at the synod held at Antioch in 341 an affirmation of faith, omitting the *homoousion*, was issued. In 342 a further council met at Sardica (mod. Sofia) to consider the case of Athanasius and to regulate the legal position of the many bishops who had suffered deposition. The easterns soon withdrew to Philippopolis (mod. Plovdiv) and held a separate meeting. Little was immediately achieved by either council, and the position became one of uneasy equilibrium until 350 when Constantius became sole ruler.

The third stage may be divided into two parts, the first, 350–356, witnessing the re-establishment of Arianism, the second, 357–361, its apparent triumph but inner disintegration. Under Constantius' leadership the Nicene party was largely crushed. In 353 at Arles the Gallican bishops were brought to heel; in 355 Liberius of Rome was exiled, to be followed by Ossius of Córdova; in 356 Hilary of Poitiers was sent to Phrygia and in the same year Athanasius had to withdraw from Alexandria to seek refuge among the desert monks. All sees were now either vacant or occupied by Arians or their sympathizers. The real Arians, who differed from their predecessors in being frank rather than evasive, now came out into the open with the declaration that the Son was "unlike" (*anomoios*) the Father. These Anomoeans, led by the bishops Aetius and Eunomius, succeeded in having their views endorsed at Sirmium in 357, but their extremism stimulated the moderates who, under Basil of Ancyra, asserted that the Son was "of similar substance" (*homoiousios*) to the Father. Constantius was initially favourable toward the Homoeousians, but soon transferred his support to the Homoeans, led by Acacius, who affirmed that the Son was "like" (*homoios*) the Father, and their views were approved in 360 at Constantinople, where all previous creeds were rejected, the term *ousia* ("substance" or "stuff") was repudiated and a statement of faith was issued stating the Son to be "*like* the Father who begot him."

The final stage of the controversy began with Constantius' death in 361. The rule of Julian the Apostate (361–363) impressed upon all parties the need for unity. Then the policy of neutrality in the west of Valentinian (364–375) enabled the orthodox majority to consolidate its position. The Arian persecution conducted by Valens (364–378) in the east and the success of the teaching of the Cappadocian trio, Basil of Caesarea, Gregory of Nyssa and Gregory of Nazianzus (*qq.v.*), led the Homoeousian majority to realize its fundamental agreement with the Nicene party. Hence the way was prepared for united action when Gratian (375–383) and Theodosius I (379–395) took up the defense of orthodoxy. Deprived of official protection and at last faced with a united opposition, Arianism could not escape the collapse that had for long threatened it. In 381 the second ecumenical council met at Constantinople; Arianism was proscribed and a statement of faith, the Nicene creed, was approved (*see* CREED). Both Gratian and Theodosius implemented these decisions with decrees that ousted all Arian office holders, and the heresy was speedily and finally extirpated.

Arianism Among the Germanic Tribes.—Although Arianism within the empire had become a spent force, beyond its borders among the Germanic tribes the situation was different. One of those present at the Homoean council of Constantinople in 360 was Ulfilas (*q.v.*), who had been consecrated bishop by Eusebius of Nicomedia. Ulfilas accepted the council's Homoean statement, and taught the similarity of the Son to the Father and the complete subordination of the Holy Spirit. He carried this teaching to the Visigoths, north of the Danube, and when they entered Italy under Alaric (who was to capture Rome itself in 410) the heresy once more found a foothold within the western empire. Yet, although it is customary to describe the beliefs of these invaders as Arian this is really a misnomer, for none of the articles of the old heresy made explicit by the Anomoeans, was professed by them. They were rather Semi-Arians, who refused to call the Son a creature, were prepared to acknowledge a Trinity, and would even accept a certain "unity" of substance, although they understood this to mean "similarity" of substance and affirmed a gradation of beings within the Trinity. The Catholic response, typified by the Athanasian creed (*see* CREED), was to emphasize the consequences of this unity of substance in the co-equality of the three persons, so that there is no subordination but a unity in Trinity.

While the Visigoths were preying upon Italy, the Vandals from Germany were pressing down into Gaul, having adopted Arianism in the sense defined immediately above as they traversed the middle Danube. In 409 they crossed the Pyrenees, thus bringing Arianism into Spain. Hard on their heels came the Visigoths, who had withdrawn from Italy, and, driving the Vandals before them across the sea into Africa in 429, they set up yet another Arian state in Spain; the Vandals, under Gaiseric and his successor Huneric, carried on a bitter persecution of the Catholics in north Africa. In the meanwhile the Franks, themselves pagan, were on the move from Belgium, and the baptism of Clovis (496 or 506?) brought an end to Arianism in Gaul. In Spain, the labours of Martin, bishop of Braga, and Leander, bishop of Seville, who converted the Arian Reccared, eventually culminated in the condemnation of Arianism at Toledo in 589. But in 603 Witteric headed a rebellion against Reccared's son, Liuva, and Arianism was temporarily restored. After Witteric's assassination in 610 it soon became a lost cause, but a following persisted until the extinction of the Visigothic kingdom by the conquering Muslims. In north Africa the successful campaign of Justinian, in part motivated by a concern for orthodoxy and the suffering of its adherents, ended the Arian domination. Justinian's defeat of the Arian Ostrogoths and reconquest of Italy, which began shortly after the death of their great leader Theodoric, only gave a short check to Arianism which was brought in again with the invading Lombards in 568. The continued loyalty and solidarity of the Catholic population and the lack of unity among the Arian churches, each limited to its particular tribe or kingdom, led to its final disappearance by the end of the 7th century, after a period of wavering. Liutprand (712–744), probably the greatest of the Lombard leaders, rejected Arianism and from then onward the movement failed to win any serious support.

Modern Holders of Arianism.—Arianism could maintain itself in force only against a background of polytheism, and once monotheism had become the generally accepted belief it showed no signs of a recrudescence. Throughout the centuries that followed its eclipse with the conversion of the Lombards, little or no hint of it is to be found, except in 18th-century England.

The questioning of fundamental beliefs that resulted from the Enlightenment, and issued in deism (*q.v.*), also led to a temporary reappearance of 4th-century Arianism in the person of Samuel

Clarke (*q.v.*), who in 1712 published *The Scripture Doctrine of the Holy Trinity* in which he maintained that Jesus was divine only by the communicating of divinity to him, being the Son of God rather than God the Son, and that the Holy Spirit was inferior to both Father and Son. Clarke, whose views were also held by his biographer, William Whiston (*q.v.*), was answered by Daniel Waterland, who in a series of works argued so convincingly that thereafter it became difficult to adopt any halfway position between orthodox Trinitarianism and complete Unitarianism, although it is to be acknowledged that some modern Unitarians are virtually Arians in that they are unwilling either to reduce Christ to a mere human being or to attribute to him a divine nature identical with that of the Father. The Christology of Jehovah's Witnesses too is a form of Arianism, Arius himself being regarded as a forerunner of C. T. Russell (*q.v.*), the founder of the movement.

ARIAS DE ÁVILA, PEDRO, commonly known as Pedrarias Dávila (1440?–1530), Spanish soldier and colonial governor, founder of the city of Panamá, was born probably at Segovia about 1440. He served in the wars against the Moors in Granada and Africa, and with ecclesiastical backing won the governorship of Castilla de Oro, later the republic of Panamá. He left Spain for that post in 1514, accompanied by 1,500 troops, his wife, two daughters and the first bishop of Darién. Upon his arrival in July he was kindly received by Vasco Núñez de Balboa (*q.v.*), who was later executed by Pedrarias.

Under Pedrarias' orders, Hernán Ponce and Bartolomé Hurtado explored in 1516 the territories comprising the modern states of Nicaragua and Costa Rica. Pedrarias himself led an unsuccessful expedition against the cacique, Urraca. His policy of eliminating all who might excel him gave him the reputation of being the most cruel and inhuman of all the Spanish captains. Replaced as governor of Panamá in 1526, Pedrarias became governor of Nicaragua and executed Francisco Hernández de Córdoba, whom earlier he had employed in the conquest of Nicaragua. Pedrarias died at León, Nicaragua, at about the age of 90. (R. G. Rr.)

ARIAS MONTANO, BENITO (1527–1598), Spanish orientalist, who directed the translation of the Antwerp polyglot Bible, was born at Frejenal de la Sierra, in Estremadura. In 1562 he was appointed consulting theologian to the Council of Trent. He retired to Peña de Aracena in 1564, wrote his commentary on the minor prophets (1571), and was sent in 1568 to Antwerp by Philip II to edit the *Biblia polyglotta* projected by Christophe Plantin (*q.v.*). The last years of his life were spent in seclusion in Seville, where he died.

He is the subject of an *Elogio histórico* by Tomás González Carvajal in the *Memorias de la Real Academia de la Historia*, vol. vii (1832).

ARIBAU, BUENAVENTURA CARLOS (1798–1862), full Catalan name, Bonaventura (Francesc Gervasi Protasi) Carles Aribau i Farriols, Spanish economist and man of letters, one of whose poems was of great importance in the revival of Catalan literature in the 19th century, was born in Barcelona, Nov. 4, 1798. He worked in Catalonia and later in Madrid, where he joined Gaspar Remisa's banking concern (1830–41) and became director of the treasury and financial secretary to the royal household. His writings voice the ideals of liberalism and the historical trend of early romanticism—as in his contributions to the Barcelona periodical *El Europeo* (1823–24), which he helped to found, and later in his *El Vapor* (1833–35). His collected Spanish essays were published as *Ensayos Literarios* (1827). Aribau edited the first four volumes of the well-known *Biblioteca de Autores Españoles* (1846–80), which he founded with Manuel de Rivadeneyra, but his fame rests chiefly on his Catalan poem *Oda a la Pàtria* (1832), marking the Catalan *renaixensa*—the re-establishment of Catalan as a literary language after an almost total eclipse of over a century. His poem, later translated into the main European languages, is a highly representative work uniting native traditions with contemporary literary ideas. It is written in Alexandrine double quatrains and contains echoes of Manzoni, Schiller and Scott. He died in Barcelona, Sept. 17, 1862.

ARICA (San Marcos de Arica), Chilean town and port near the Peruvian border, a free port for Bolivia and Peru. Pop. (1960) 43,344. Since May 1, 1930, it has been part of Tarapacá province (*q.v.*). Arica's main economic function is the handling of transit trade. The irrigated Lluta and Azapa valleys, which partially supply trade products for Arica, have a long agricultural history. Inca occupation may date from 1250. The Spanish, who used Arica's roadstead in the 1550s, gave the community city status in 1570.

Disasters that have befallen the city include sacking by pirates and the Chilean army, numerous earthquakes and a pair of tidal waves, one of which carried an American sailing vessel .3 of a mile inland. During the War of the Pacific, El Morro, the precipitous headland overlooking the city, was the scene of a battle memorable for the fanatic but fruitless resistance of the entrenched Peruvians. Chile controlled the city thereafter (June 1880). The treaty of Ancón (1883) outlined a procedure for determining ultimate sovereignty of the area, but the question of Chilean possession was not definitely resolved until 1929. The city is the terminus for a 39-mi.-long railway (completed 1854) to Tacna, Peru, and for a 285-mi.-long railway to La Paz, Bolivia (completed 1913). (J. T.)

ARICIA, an ancient city in Latium, the modern Ariccia in the Italian *regione* of Lazio, 16 mi. S.E. of Rome on the Via Appia. The nucleus of the old town originally lay 1,352 ft. above sea level above a volcanic depression known as Valle Ariccia; remains of its walls are traceable. After the construction of the Via Appia in 312 B.C. the inhabitants of Aricia moved southwest to form the lower town close to the road; about 250 yd. of fine substructions of polygonal masonry survive. There are remains of the walls of the lower town, of the *cella* of a temple of the 2nd century B.C. and also of later buildings connected with the post station and baths. Aricia was one of the oldest cities of Latium, and the name of the inhabitants, Aricini, with its ending *-cini*, suggests that an earlier stratum of population in Latium with names ending in *-ci* (*cf.* Volsci, Osci) may have been absorbed by a later stratum with names ending in *-ni* (*cf.* Latini, Sabini, etc.). Aricia was an early opponent of Rome. In the 6th century it opposed Tarquinius Superbus and was helped by Aristodemus of Cumae against the Etruscans at the battle of Aricia. It was a meetingplace of the Latin league, and the Aricini took part in the battle of Lake Regillus (early 5th century) and in the Latin War (340–338 B.C.), after which they received Roman citizenship. Aricia remained a prosperous *municipium* until the barbarian invasions. It was celebrated for the cult of Diana Nemorensis, whose temple was in the forest near Aricia, beside Lake Nemi. The priest, called *rex nemorensis*, acquired office by killing his predecessor and held it only so long as he could defend himself from any stronger rival.

Bibliography.—G. de Sanctis, *Storia dei Romani*, vol. i (1907); J. G. Frazer, *The Golden Bough*, part i (1915); A. E. Gordon, "Cults of Aricia," *University of California Publications in Classical Archaeology*, vol. ii (1934).

'ARID, AL ('Aridh) is the central district of Najd, the premier province of Saudi Arabia, containing the capital, Riyadh (*q.v.*). It occupies the width of the Tuwayq plateau between Al Mahmal (north) and Al Kharj (south) districts, extending east and west to the sand belts of Ad Dahna' and Qunayfidhah. In it are numerous oasis settlements, of which the most important are Ad Dir'iyah and Al 'Uyaynah in Wadi Hanifah; Durma, Al Ghatghat and Muzahimiya in Al Batin plain (west); Sudus and Ar Rimah. Their yeoman farmers, always renowned for their sturdy independence and martial qualities, at first resisted the Wahhabi (*q.v.*) movement in the mid-18th century but later became its stoutest champions until Wahhabism itself merged with

the latitudinarianism of the oil economy of modern times. (H. St. J. B. P.)

ARIÈGE, a frontier *département* of southern France, is bounded on the south by Spain and Andorra, on the west and north by Haute-Garonne, and on the east by Pyrénées-Orientales and Aude. Area 1,888 sq.mi. Pop. (1962) 137,192. The *département* extends to the crest of the central Pyrenees, where the mountain system attains its maximum development in breadth and height, with peaks above 9,000 ft. culminating in Montcalm (10,105 ft.), and passes above 6,000 ft., so near the snow line as to be impassable for a long winter period. No railway line crosses Ariège but the Col de Puymorens has long provided an important road route into Spain. North of the crystalline core of the Pyrenees the flanking belts of folded sedimentary rocks form parallel ridges and valleys. The outermost ridge, the Plantaurel, intersected by the Ariège river, drops steeply to the lowlands of Aquitaine. Controlling the Ariège gateway into the mountains and the approach to the Col de Puymorens, Foix (*q.v.*) was the centre of a county that retained its distinctness until the French Revolution. This ancient county now forms the nucleus of the *département,* which also includes parts of Languedoc and Gascony (*qq.v.*). Although it largely comprises the upper basin of the river Ariège, the *département* extends westward into that of the Salat headstream of the Garonne.

A pastoral economy prevails in the high mountains, and as use of the summer pastures from the French side has decreased, more use has been made of them by Spanish shepherds. There are some forests, but within the forest zone farming has made extensive encroachments. Maize, haricot beans, potatoes and deciduous fruits are grown in the lower valleys, and the mixed farming that is so typical of the lowlands of Aquitaine is practised in the lower country in the north of the *département.* Pockets of highgrade iron ore have been extensively worked in the mountains and there is still some exploitation of it at Puymorens and Montels. Iron-working industries also survive, especially at Pamiers. There are also deposits of lead and zinc ore, but more important than the ore bodies today are the deposits of gypsum and anhydrite at Tarascon (*q.v.*) and the talc of Luzenac. Several hydroelectric power stations are in operation and others are under construction, while the tourist industry is bringing new life to spa towns such as Aix-les-Thermes and other resorts along the roads that are being improved for motor traffic. The outer limestone ranges have picturesque gorges, river tunnels, and caves that are famous for the archaeological remains they have yielded. The grottoes of Le Mas d'Azil and Niaux, among Paleolithic sites, are especially worthy of mention. Foix, the departmental capital, Pamiers and St. Girons give their names to the three *arrondissements.* Pamiers is the seat of the bishopric that is co-extensive with the *département.* The court of appeal and educational headquarters (*académie*) are at Toulouse. (Ar. E. S.)

ARIEL, a biblical word used in several ways. In the Revised Standard Version it is given as an untranslated common noun in II Sam. xxiii, 20 and I Chron. xi, 22 ("he smote two ariels of Moab"), translated in the King James Version as "lionlike men" and in the Douai Version as "lions." Isa. (ch. xxix) uses Ariel as a synonym for Jerusalem, and in Ezra viii, 16 it is the name of one of Ezra's companions.

In Shakespeare's comedy *The Tempest* the spirit of the air delivered from captivity by Prospero, and thereafter his devoted familiar, is called Ariel. Milton used the name for one of the fallen angels in *Paradise Lost.*

ARIES (the "Ram"), in astronomy, a small constellation with three easily visible stars, the first sign of the zodiac. Aries is denoted by the sign ♈, in imitation of a ram's head. The "first point of Aries," which is now far away from the constellation and is situated in Pisces, is the zero from which the right ascensions and longitudes of the stars are measured. It is at the crossing point of the equator and ecliptic on the celestial sphere.

According to a Greek myth, Nephele, mother of Phrixus and Helle, gave her son a ram with a golden fleece. To avoid the evil designs of Ino, their stepmother, Phrixus and Helle fled on the back of the ram, and reaching the sea, attempted to cross. Helle fell from the ram and was drowned (hence the Hellespont); Phrixus, having arrived in Colchis, sacrificed the ram to Zeus, who placed it in the heavens as the constellation.

ARIKARA (Ricara or Ree), northernmost Caddoan-speaking Plains Indians, related linguistically and culturally to the Pawnee, Wichita and Caddo (*q.v.*). First reported in the early 1700s as consisting of several thousand persons living in many villages along the Missouri river in South Dakota, they continually moved upstream and lost population during the 19th century. In the 1860s they joined the Hidatsa-Mandan tribes at Ft. Berthold, N.D. where they have remained. By 1885 their village was dispersed into individual families on scattered farmsteads. Construction of the Garrison reservoir dam and discovery of oil in the Williston basin forced another removal to new homes in the 1950s. In the 1960s they constituted a population of about 700 on the Fort Berthold reservation (*see* Hidatsa).

Originally marginal horticulturalists surrounded by nomadic tribes of hunters, they lived in large permanent villages of earth lodges. Corn, beans, squash and sunflower crops were maintained by the women. Communal bison hunts under the direction of the men interspersed the horticultural cycle. Village activities were controlled by reference to a sacred bundle in the hands of a priest. This office and chiefly posts tended to be the hereditary prerogative of a few leading families. Lower posts associated with organized military, dancing and curing societies fell to the men of commoner families. Different personality ideals were demanded of the two groups. Matrilineal emphasis is indicated by high status for women, the avunculate, sororal polygyny and important maternal fertility roles in the religion. Their occupation of the banks of the Missouri for some 500 years is suggested by archaeological evidence. Comparative ethnology indicates the cultural roots of Caddoan-speaking peoples lay in the prehistoric mound-building cultures of the lower Mississippi valley with some important similarities to customs of the high cultures of Middle America. (*See* Plains Indians.)

See B. Neal, *Last of the Thundering Herd* (1960); J. J. F. Deetz, *The Dynamics of Stylistic Change in Arikara Ceramics* (1965). (P. Ho.)

ARIMASPI, an ancient people in the extreme northeast of Scythia, probably the eastern Altai. All accounts of them go back to a poem by Aristeas of Proconnesus, from whom Herodotus drew his information. They were supposed to be one eyed and to steal gold from the griffins that guarded it (the district contains gold-bearing ores). In art they are usually represented as richly dressed Asiatics, picturesquely grouped with their griffin foes; the subject is often described by poets from Aeschylus to Milton. They are so nearly mythical that it is impossible to insist on their identification with any historical people. *See* Scythians.

ARIMINUM: *see* Rimini.

ARIOBARZANES, the name of a Persian satrap of Hellespontine Phrygia, a king of Pontus, and three successive kings of Cappadocia. Ariobarzanes (4th century b.c.), son of a Persian nobleman, Mithradates, was satrap of Hellespontine Phrygia about 387 b.c. He cultivated the friendship of Athens and Sparta and led the revolt of the western satraps against Artaxerxes II (*c.* 366). When the revolt collapsed he was killed (*c.* 360).

Ariobarzanes (3rd century b.c.) was king of Pontus *c.* 265–255 b.c. in succession to his father Mithradates II.

Ariobarzanes I Philoromaios (1st century b.c.) became king of Cappadocia *c.* 95 b.c. Driven out by Mithradates VI of Pontus in 93 and 88 he was restored by the Romans in 92 and 85 b.c. In 63 he abdicated in favour of his son Ariobarzanes II Philopator. His who was king of Cappadocia till his assassination in 52 b.c. His son Ariobarzanes III Eusebes Philoromaios then succeeded him. Ariobarzanes III's rule was menaced by internal disaffection, and he owed large sums of money to Pompey, Marcus Junius Brutus and other prominent Romans. Cicero befriended him, as did Pompey and Caesar. He was put to death by Gaius Cassius Longinus in 42 b.c. on a charge of conspiracy. (R. H. St.)

ARION, the name of two figures in Greek legend.

1. Arion of Methymna in Lesbos, a semilegendary poet and musician, friend of Periander, tyrant of Corinth. He flourished about 625 b.c. He is said to have invented the dithyramb; *i.e.,* he gave it literary form. The name Cycleus given to his father indicates

the connection of the son with the cyclic or circular chorus of the dithyramb. No genuine work of his survives. Of his life, only the following story, popular in antiquity, is known.

After a successful "tour" in Sicily and Magna Graecia, Arion embarked at Taras (Tarentum) in a Corinthian vessel. The sight of his treasure roused the cupidity of the sailors, who resolved to possess themselves of it by putting him to death. Arion, as a last favour, begged permission to sing a parting song. The sailors, desirous of hearing so famous a musician, consented, and the poet, standing on the deck of the ship, in full minstrel's attire, sang a dirge accompanied by his lyre. He then threw himself overboard; but instead of perishing, he was miraculously borne up in safety by a dolphin, supposed to have been charmed by the music. Thus he was conveyed to Taenarum, whence he proceeded to Corinth, arriving before the ship. Periander, tyrant of Corinth, at first incredulous, eventually learned the truth by a stratagem. Summoning the sailors, he demanded what had become of the poet. They affirmed that he had remained behind at Tarentum; upon which they were suddenly confronted by Arion himself, arrayed in the same garments in which he had leapt overboard. The sailors confessed their guilt and were punished. Arion's lyre and the dolphin were translated to the stars.

Herodotus and Pausanias both refer to a bronze figure at Taenarum that was supposed to represent Arion seated on the dolphin's back. But this is quite as likely to be Phalanthus, the founder of Tarentum, who was commonly represented on the coins of that city riding on a dolphin.

2. Arion or Areion, a wonderful horse, offspring of Poseidon and Demeter Erinys (*see* DEMETER), which belonged to Adrastus, and by its speed saved its master, the only leader to escape from the disaster of the Seven against Thebes. (T. V. B.)

ARIOSTO, LUDOVICO (1474–1533), Italian poet and author of the *Orlando Furioso*, the most perfect expression of Renaissance classicism, was born on Sept. 8, 1474, at Reggio Emilia, where his father, Count Niccolo, of a Ferrarese family, was commander of the citadel; his mother was Daria Malaguzzi Valeri. At the age of ten he moved with his family to Ferrara, and always considered himself a Ferrarese. Although he early showed an inclination for poetry, his father intended him for a legal career, and he studied law unwillingly at Ferrara from 1489 to 1494. He then devoted himself to literary studies under Gregorio Elladio di Spoleto, who, however, left Ferrara in 1499 without having taught his pupil Greek.

When Niccolo died in 1500, Ludovico, being the eldest son, had to provide for his five sisters and four brothers: one of these, Gabriele, a cripple, remained with him all his life, helping in the administration of their shaky estates and sharing his interest in learning and poetry. Ludovico had to give up his dream of a peaceful life devoted to humanistic studies and seek public employment in order to provide for his family. In 1502 he became commander of the citadel of Canossa and in the following year entered the service of Cardinal Ippolito d'Este, the son of Duke Ercole I. His duties as a courtier were in sharp contrast with his simple tastes and, beside accompanying his master on dangerous expeditions and traveling for him on diplomatic missions, he had to be in constant attendance on him. In 1509 he followed the cardinal in the campaign against Venice and, in 1512, he went to Rome with Alfonso, the cardinal's brother, who has succeeded Ercole as duke in 1505, in an attempt to placate the pope, Julius II. Having been unsuccessful, they both had to flee over the Apennines to escape the pope's wrath.

In the hope of finding a situation at the Roman court which would allow him to follow his literary inclination, Ariosto went to Rome in 1513, after the election of Leo X. His hope proved vain and he returned to the cardinal, but when Ippolito was created bishop of Buda in 1517, Ludovico refused to follow him to Hungary and was dismissed. In the following year he entered into the personal service of Duke Alfonso. He was thus able to remain in Ferrara, near Alessandra Benucci, whom he had met in 1513 and who became his faithful companion, although he did not marry her until 1527 (secretly, in order not to lose certain ecclesiastical benefices). In 1522, however, financial necessity compelled him to accept the post of governor of the Garfagnana, in the wildest part of the Apennines. The province was torn by rival factions and brigands and Ariosto showed great skill and wisdom in keeping order.

In 1525 he was at last able to return to Ferrara and, with the money saved during his term of office he bought a little house with a garden. Thus his dreams of a peaceful life devoted to study and poetry came true, and he spent his last years with Alessandra and his own son Virginio, cultivating his garden and revising the *Orlando Furioso* which had been first published in 1516 and was published for the third time in 1532, a few months before his death on July 6, 1533.

Minor Works.—Ariosto's minor works are not on the same level as his masterpiece, although they reveal the same reflective and ironical attitude. His Latin verses, inspired by Tibullus and Horace, were mainly composed in his early years. Although they do not compare in technical skill with those by Marco Antonio Flaminio, Andrea Navagero, Giovanni Cotta and Pietro Bembo, they are much more sincere in feeling. Love is the main subject of his vernacular poems (sonnets, *canzoni* and elegies in *terza rima*) which are his least original work. More important is his *Satire* (1517–25), seven satires which derive from Horace's *Sermones* (*Satires*): the first, written in 1517 when he had refused to follow the cardinal abroad, is a noble assertion of the dignity and independence of writers; the second criticizes ecclesiastical corruption; the third moralizes on the need to refrain from ambition; the fourth deals with marriage; the fifth and sixth describe the personal feelings of the author when kept away from his family by his masters' selfishness; the seventh, addressed to Bembo, points out the vices of humanists and reveals the poet's sorrow at not having been allowed to finish his literary education. Ariosto's five comedies, *Cassaria* (1508), *I Suppositi* (1509), *Il Negromante* (1520), *Lena* (1529) and *I Studenti* (completed by his brother Gabriele and published posthumously under the title *La Scolastica*) mark the beginning of the Renaissance theatre and introduce the imitation of Latin comedy. Although based on the classics, they are all inspired by contemporary life.

The "Orlando Furioso."—Many of the elements scattered in Ariosto's minor works find their poetical development in the *Orlando Furioso*, the poem on which Ariosto worked for nearly 30 years, from *c.* 1502 or 1503 to the end of his life. In its first edition, published in Venice in 1516 at the cardinal's expense, it consisted of 40 cantos, as did the second edition (Ferrara, 1521), in which, however, some revisions of language and style show the influence of Bembo. Such revision is still more evident in the third edition (Ferrara, 1532), in which the poem was extended to 46 cantos. In this final version Ariosto's style achieved its perfection.

The *Furioso* is a continuation of Boiardo's *Orlando Innamorato* which places Orlando in imaginary circumstances. Ariosto's work consists of a number of episodes derived from the epics, romances and heroic poetry of the middle ages and early Renaissance. The poem, however, achieves homogeneity by the author's skill and economy in handling the various episodes. Despite complete disregard of unity of action (which was to become compulsory in the second half of the century) it is possible to identify three principal nuclei round which the various stories are grouped: Orlando's passion for Angelica, the war between Christians and pagans near Paris and the love between Ruggero and Bradamante. The first is the most important, particularly in the first part of the poem; the second represents the epic background to the whole narrative; the third is merely introduced as a literary courtesy, since the Este family was supposed to owe its origin to the union of the two lovers. The main unifying element, however, is the personality of Ariosto himself, who confers his own refined spirituality on all his characters. Sensual love is the prevailing sentiment; but it is tempered by the author's ironical attitude and artistic detachment. The metrical form of the poem is the *ottava*, according to a tradition which continued from Boccaccio to Politian and Boiardo.

In substance and form, the *Orlando Furioso* can be regarded as the most perfect expression of the artistic tendencies and spiritual

attitudes of the Italian Renaissance. It enjoyed immediate popularity all over Europe and greatly influenced the literature of the Renaissance. It was translated into French by Jean de Gouttes in 1543 and by Jean Formier in 1555, into Spanish by Jeronimo de Urrea in 1549, and into English by Sir John Harington in 1591.

Modern editions of Ariosto's works are: *Orlando Furioso*, ed. by L. Caretti (1954); *Opere minori*, ed. by C. Segre (1954), with a bibliography. For a portrait of Ariosto *see* ITALIAN LITERATURE.

ARIOVISTUS (1st century B.C.), king of the Suebi, a Germanic people, who led a mixed force of German tribes into Gaul at the invitation of the Sequani, perhaps as early as 71 B.C. Having defeated the Aedui at a place called Magetobriga in 61 B.C., he made them give hostages to the Sequani and settled Germans in territory of the Sequani on the left bank of the Rhine. The Romans, apparently not appreciating the danger at first, formally recognized Ariovistus as "friend of the Roman people" in 59; but in the spring of 58, after Julius Caesar's defeat of the Helvetii, a convention of the tribes of central Gaul, headed by the Aedui, at Bibracte asked the Romans for help. Caesar sent a courteous message to Ariovistus asking him to return the hostages of the Aedui and bring no more Germans into Gaul: Ariovistus refused and hostilities began. Caesar occupied Vesontio (Besançon) in the territory of the Aedui, and in the preliminary maneuvering Ariovistus managed to split Caesar's army and attack one division of it (somewhere north of the modern Mulhouse) in mid-September 58 B.C. A general engagement followed, doubtful at first, which was decided by the Roman reserve under P. Licinius Crassus. Ariovistus then fled over the Rhine. Although Caesar crossed the Rhine in 55 B.C. to affirm Roman control of the Rhine frontier, he seems to have left Ariovistus' settlements undisturbed.

See T. R. Holmes, *Caesar's Conquest of Gaul* (1911) and *The Roman Republic*, vol. ii (1923).

ARISTAENETUS (fl. 5th or 6th century A.D.), Greek letter writer, is credited with having written two extant books of love stories, in the form of letters. The subjects are borrowed from the erotic elegies of Alexandrian writers and the language is a patchwork of phrases from Plato, Lucian, Alciphron and others. The author was formerly identified with Aristaenetus of Nicaea, who perished in an earthquake at Nicomedia, A.D. 358, but internal evidence points to a much later date.

See R. Hercher, *Epistolographoi Hellenikoi* (1873); *The Love Epistles of Aristaenetus*, trans. by N. B. Halhed and R. B. Sheridan (1771, etc.).

ARISTAEUS, a divinity whose worship was widely spread throughout ancient Greece, but concerning whom the myths are somewhat obscure. The name is derived from the Greek *aristos*, "best." According to the generally received account, Apollo carried off the nymph Cyrene from Mt. Pelion in Thessaly and conveyed her to Libya, where she gave birth to Aristaeus. Having been brought up by the Horae or by the centaur Chiron, Aristaeus left Libya and went to Thebes. There he received instruction from the Muses in the arts of healing and prophecy and became the son-in-law of Cadmus and the father of Actaeon (*q.v.*). He is said to have visited Ceos, where, by erecting a temple to Zeus Ikmaios (the giver of moisture), he freed the inhabitants from a terrible drought; for this service he was himself honoured as Zeus Aristaios. After traveling extensively, Aristaeus reached Thrace, where he finally disappeared near Mt. Haemus. While in Thrace he is said to have caused the death of Eurydice, who was bitten by a snake while fleeing from him.

Aristaeus was essentially a benevolent deity. He introduced the cultivation of bees (Virgil, Georgics) and the vine and olive; he was the protector of herdsmen and hunters; he warded off the evil effects of the dog star, and possessed the arts of healing and prophecy. He was often identified with Zeus, Apollo and Dionysus. In ancient sculptures and on coins he is represented as a young man, dressed like a shepherd, and sometimes carrying a sheep on his shoulders. (T. V. B.)

ARISTAGORAS (d. 497 B.C.), Milesian statesman prominent in the Ionian revolt that led to the first of the Greco-Persian Wars, was son-in-law and cousin of Histiaeus, tyrant of Miletus. He acted as regent while Histiaeus was detained at the court of Darius. In 499 B.C. he persuaded the Persians to join him in an attack upon Naxos, but he quarreled with the Persian commander, who, according to Herodotus, warned the Naxians, so that the expedition failed. Finding himself out of favour with Persia, Aristagoras, prompted by a message from Histiaeus, raised Ionia in revolt. He then went to Greece (winter 499–498) to secure help and induced the Athenians to send the force which attacked Sardis. After the failure of the revolt, Aristagoras emigrated to Myrcinus in Thrace, where he was killed in an attack on a Thracian stronghold.

ARISTARCHUS OF SAMOS, Greek astronomer, flourished about 270 B.C. and is famous for having been the first to maintain that the earth revolves around the sun. On this ground Cleanthes the Stoic declared that he ought to be indicted for impiety.

Aristarchus' only extant work is a short treatise *On the Sizes and Distances of the Sun and Moon;* here he obtains, by geometry, certain results as regards sizes and distances which are inaccurate because of the incorrectness of the assumptions, due to the imperfect state of knowledge at the time. The heliocentric hypothesis does not appear in the treatise, but a quotation in the *Arenarius* of Archimedes from another work of Aristarchus proves that he anticipated the great discovery of Copernicus. Moreover, Copernicus himself was clearly aware of the achievement of Aristarchus, for he mentioned it in a passage which he afterward suppressed.

Aristarchus is also said to have invented a hemispherical sundial.

The Greek text of the extant treatise was first edited by Wallis (1688); for a new Greek text with English translation and notes *see* T. L. Heath, *Aristarchus of Samos* (1913).

ARISTARCHUS OF SAMOTHRACE (*c.* 220–*c.* 143 B.C.), Greek critic and grammarian, noted for his contribution to Homeric studies. He settled in Alexandria, where he was a pupil of Aristophanes of Byzantium, and, *c.* 153 B.C., became chief librarian there. Later he withdrew to Cyprus, where he died. Aristarchus founded a school of philologists, called after him "Aristarcheans," which long flourished in Alexandria and afterward at Rome. Cicero and Horace regarded him as the supreme critic. His works fall into three categories: (1) two editions of the text of Homer and editions of Hesiod, Pindar, Archilochus, Alcaeus, Anacreon; (2) commentaries stated in the *Suda* lexicon to number 800 on these poets, as on Aeschylus, Sophocles, Aristophanes and Herodotus; (3) critical brochures on particular problems, especially Homeric. In the time of Augustus two Aristarcheans, Didymus and Aristonicus, undertook the revision of his work on Homer, and the extracts from these two writers in the Venetian scholia to the *Iliad* give an idea of his achievements. Although there is some difference of opinion on the point, it would seem that the vulgate text of Homer has been little affected by the Alexandrian editions, except perhaps for the exclusion of surplus lines.

ARISTEAS, LETTER OF, a pseudonymous Jewish letter variously dated between 200 B.C. and A.D. 33, in which is described in legendary form, the origin of the Greek translation of the Old Testament known as the Septuagint (*q.v.*). The author represents himself as a Gentile Greek, but was really an Alexandrian Jew who lived under one of the later Ptolemies.

BIBLIOGRAPHY.—*See* modern editions of the Greek text by H. St. J. Thackeray in H. B. Swete (ed.), *Introduction to the Old Testament in Greek* (1900), and by P. Wendland (1900); and H. St. J. Thackeray, *The Letter of Aristeas* (1917), Eng. trans. with critical introduction and bibliography. *See* also H. G. Meecham, *The Letter of Aristeas* (1935).

ARISTIDES (ARISTEIDES) THE JUST (b. late 6th century B.C.), son of Lysimachus, Athenian statesman and general and founder of the Delian league (*q.v.*). Nothing is known of his early life except that he is said to have been a follower of the reformer

Cleisthenes (*q.v.*), but later he must have been prominent among the party that favoured resistance to Persia, since he commanded the regiment of his own tribe Antiochis at Marathon (490 B.C.), and in the spring of 489, before Miltiades' fall from power, he was elected archon for the coming year. He is not heard of again till 482, when he was ostracized, probably because he opposed Themistocles' plan, put through at this time, to use the silver from a new vein of the mines at Laurium to build a large fleet; Aristides may have preferred to build up Athens' land forces. Recalled with other exiles before Salamis (480), he loyally supported Themistocles, and led the Athenian infantry that landed on the island of Psyttaleia late in the battle and annihilated the Persian force stationed there.

He commanded the Athenian force at Plataea (479) as general with special powers. Herodotus makes much of the Athenian contribution to the Greek victory; Plutarch adds the suppression of an oligarchic conspiracy in the Athenian army. Next year (478) Aristides commanded the Athenian contingent of 30 ships in the fleet that Pausanias led to Cyprus and Byzantium. There, toward the end of the year, the eastern Greek allies revolted from Spartan control and offered their allegiance, through Aristides, to Athens. This was the origin of the Delian league, which was to become the Athenian empire. In the winter Aristides was entrusted with the assessment of the members' contributions, a task he carried out to general satisfaction, using as his basis the Persian assessment made by the satrap Artaphernes in 493, after the Ionian revolt. The military command of the league's forces passed to Cimon (*q.v.*), and there is no reliable information about Aristides' later career or the date of his death.

The foundation of the Delian league was his great achievement, based on Athens' naval power and the trust he himself inspired. His assessment was the conspicuous instance of his "justice" though not the origin of his reputation. Inevitably, his poverty became a legend, though he must have been a man of substance to qualify for the archonship; but a state pension was paid to some of his descendants. The view that he was a democratic reformer seems traceable to Aristotle and his school, who thought he planned from the start the development the empire underwent later; in fact his main associations are with Miltiades and Cimon, the enemies of the democratic leaders Xanthippus and Ephialtes. He is said to have collaborated with Themistocles in the winter of 479/478 over the refortification of Athens, but thereafter Themistocles' influence diminished while that of Aristides and Cimon increased.

ARISTIDES (ARISTEIDES) OF MILETUS (*c.* 150–100 B.C.), author of short narratives who wrote in Greek the very popular work, lost except for fragments, the *Milesiaca* (Milesian tales), a collection of erotic stories, often obscene. They were translated into Latin by the Roman historian Cornelius Sisenna in 1st century B.C. The Latin form of the title *Milesiae* (*fabulae*) became the name given to similar collections of erotic stories such as the *Satyricon* of Petronius (d. A.D. 66) and the *Metamorphoses* of Apuleius (b. *c.* A.D. 125). *Italica, Persica* and *Sicelica* are wrongly credited to this Aristides.

ARISTIDES (ARISTEIDES), **PUBLIUS AELIUS** (surnamed THEODORUS) (2nd century A.D.), Greek rhetorician and sophist, wrote a number of treatises and speeches which because of their correctness of style and eloquence, were destined to become school books and the subject of commentaries. After studying at Pergamum and Athens he lived at Smyrna and when it was destroyed by an earthquake in 178, he wrote an account of the disaster to the emperor Marcus Aurelius and induced him to rebuild the city. Aristides' extant works consist of two small rhetorical treatises on political and simple speech, with Demosthenes and Xenophon as models, and 55 declamations of which only the *Panathenascus* and the *Encomium of Rome* were actually delivered. Of the others, *The Sacred Discourses* deal with his illness and with miraculous cures and the rest are panegyrics or treat subjects from Greek history.

See W. Schmid (ed.), *Aristidis qui feruntur Libri Rhetorici II;* J. E. Sandys, *A History of Classical Scholarship*, vol. i (1921, etc.).

ARISTIDES, QUINTILIANUS (2nd or 3rd century A.D.), Greek Neoplatonist, author of a treatise on music (*Peri musikes*), which was regarded by Byzantine and Arab theorists as an important source for the study of Greek music, a judgment generally accepted by modern scholars. The treatise was first published in Marcus Meibohm's collection of writings by Greek musical theorists in 1652. A critical edition by A. Jahn appeared in 1882; and R. Schäfke published a German translation and commentary in 1937. (E. J. Wz.)

ARISTIDES, APOLOGY OF, one of the earliest (2nd century) Christian apologetic works. *See* APOLOGISTS, EARLY CHRISTIAN.

ARISTIPPUS (*c.* 435–356 B.C.), of Cyrene, was regarded in antiquity as the founder of the Cyrenaic school of philosophy (*see* CYRENAICS). He belonged to the circle of Socrates but taught for pay and led the wandering life typical of the Sophists, among whom Aristotle reckons him. Visits to the court of the elder and perhaps of the younger Dionysius of Syracuse are attested. No genuine writings survive, but numerous anecdotes, such as gather round a striking personality, make a consistent picture of a hedonist, proud of the practical good sense which makes him kindly, witty, adaptable, always ready to turn circumstances to the best account, the master and not the slave of his pleasures. The tenets of the Cyrenaics are recorded only in a form which, because of its vocabulary and its attention to the views of Epicurus, cannot be attributed to Aristippus but may perhaps be ascribed to his grandson, who had the same name. Nevertheless, the elder Aristippus was clearly the source of the school's principal doctrines. (F. H. SH.)

ARISTO (ARISTON) OF CHIOS (*c.* 250 B.C.), a Stoic philosopher and pupil of Zeno, though he approximated more closely to the Cynic school. He considered only ethics worthy of study, and in that only general and theoretical questions. He rejected Zeno's doctrine of desirable things, intermediate between virtue and vice. There is only one virtue—an intelligent, healthy state of mind (*hygieia*). Aristo is often confounded with Aristo(n) of Ceos, head of the Peripatetics about 230 B.C. *See* STOICS.

ARISTOBULUS OF PANEAS (fl. *c.* 160 B.C.), Jewish philosopher, a forerunner of Philo (*q.v.*) in the attempt to reconcile Greek philosophy with Judaism, lived at Alexandria in Egypt under the Ptolemies. According to some Church Fathers he was a Peripatetic, but he also used Platonic and Pythagorean concepts. Following the Stoic method of allegorizing Greek mythology, he interpreted the anthropomorphic references to God in Scripture as allegorical expressions. Mosaic laws such as that governing the Sabbath he explained symbolically. He tried to prove that the principal Greek philosophers and poets had borrowed from Judaism, but his quotations from Greek literature are often inaccurate or plainly false. Fragments of his work on the Mosaic laws are preserved in the *Praeparatio Evangelica* of Eusebius of Caesarea and in the *Miscellanies* of Clement of Alexandria.

See E. Schürer, *A History of the Jewish People in the Time of Jesus Christ*, vol. ii (1886); M. Joel, *Blicke in die Religionsgeschichte*, vol. i (1880). (A. AN.)

ARISTOCRACY today is a term referring to the nobility, and the qualities believed to be aristocratic are those associated with a hereditary nobility. These qualities cannot be simply enumerated, as was often done in the past, by reciting the traits, such as those characteristic of the "gentleman," that have been prevalent in western culture; for in each culture the nobility will exhibit those traits that are most highly prized in the particular culture's value and belief system. Thus *noblesse oblige* may mean participation in war and government in England, while it may mean the shunning of these very activities to a Brahmin. In contemporary usage, both aristocracy and nobility have acquired a somewhat antiquated flavour, and the term preferred by social

scientists, at least, is "elite." It is noteworthy how many of the generalizations at present discussed under that heading are found in older writers, such as Montesquieu, under the heading of aristocracy.

Aristocracy did not always have such a broad and rather indefinite connotation. Indeed, at its birth it did not refer to a class at all. In the Greek context aristocracy referred to those cities or *poleis* in which a small group governed who considered themselves (and usually were so considered by their fellow citizens) "the best." In all those cities that at the height of the struggle between Athens and Sparta were associated with Sparta, the aristocracy ruled. Thucydides describes the quick alteration between aristocratic and democratic factions which the shifting fortunes of that great and dramatic fight for supremacy in the Greek world brought with them.

This dichotomy between the rule of the many and the rule of the few is the true core of the arguments about government in both Plato and Aristotle, as well as the many writers who followed them. But the philosophers were unwilling to accept the popular connotations. Instead of the hereditary and plutocratic aristocracies, they pleaded for an aristocracy of merit, and they would see that merit in the possession of virtue, or *arete*. But whereas Plato stressed wisdom, in the transcendent sense of his idealistic philosophy, as the prime basis of virtue, Aristotle took a more traditional Greek view of virtue, though he incorporated the capacity to reason profoundly and thus achieve wisdom along with other kinds of superior performance.

What in the perspective of the Peloponnesian War had been the antithesis between Athens and Sparta became in the world of Roman thought the fight between nobles and plebeians. Polybius suggested that the blending of the aristocratic and the democratic principles (with a dash of monarchy) had given Rome its powerful government. He built upon Aristotle's earlier suggestion that a combination of aristocratic and democratic principles would result in the best form of government—ideal state, as it is often put. This notion continued to appeal to political thinkers not only among the Romans but also in the middle ages and down to modern times. Thomas Aquinas and Marsilius of Padua, no less than James Harrington and Machiavelli, were attached to it. But in the course of the 17th century the idea became transformed into that of the separation of powers.

Aristocracy had a considerable appeal to some of the U.S. founding fathers. There can be little doubt that the republicanism of men like George Washington, Alexander Hamilton and John Adams was aristocratic rather than democratic. On the other hand, Thomas Jefferson, although perhaps the most aristocratic of them all as far as personality was concerned, decried the aristocratic tendencies of many of his friends, especially the great plantation owners of the south, and raised the banner of democracy against them. Thus it may be said that the antithesis between aristocracy and democracy was one of the central themes of early U.S. party politics, with the Federalists standing for aristocracy, the Jeffersonian Republicans for democracy. It might be added, though, that the issue was a confused one, further complicated by the slavery problem. In the defense of slavery, some of the most extreme statements of an aristocratic and elitist nature in America were penned.

Aristocracy as the rule of the few has thus been recurrently associated with both monarchy and democracy. Evidently, a prince must seek to secure as helpers some group of people who will not only assist in governing but who will also provide a broader base for legitimacy and authority. Similarly, a democracy will strive to find "the best" to wield temporary power and rule in accordance with the people's wishes. This observation has led to the proposition that at bottom all governments are aristocracies, and the concept of the ruling class has served to emphasize this insight. Ruling class and elite are becoming synonymous terms to describe as actual what Plato and Aristotle argued for as ideal. But the "virtue" of the few who rule is once more seen as the capacity to succeed, rather than as a transcendent quality of goodness. Those who expound such notions often forget that to say "those few who succeed (the elite) always rule" is little more than a tautology that obscures the dialectic challenge inherent in the idea of aristocracy as "truly best."

ARISTODEMUS, the name of four personages in the ancient world, not all of them historical.

1. The legendary father of the twins Eurysthenes and Procles who were traditionally regarded by the Greeks in general as the founders of Dorian Sparta; the Spartans themselves, according to Herodotus, ascribed the foundation to Aristodemus.

2. King of Messenia in the 8th century B.C., the time of the Spartan conquest of Messenia. Although he was an historical figure, much that is related of him by Pausanias (writing in the 2nd century A.D.) is legend.

3. A Spartan, often included among the Seven Wise Men of Greece.

4. A tyrant of Cumae who defeated the Etruscans in the late 6th century B.C.

ARISTOLOCHIA, a genus of about 300 species of woody vines or herbs of the family Aristolochiaceae (birthworts), chiefly tropical. The flower forms a tube swollen at the base. The name (Gr. *aristos*, "best"; locheia, "childbirth") alludes to its reputed aid in parturition. The birthwort (*A. clematitus*) is a European species, found sometimes in England, apparently wild, on ruins and similar places, but not native. In the United States it occasionally escapes from cultivation from New York to Maryland. The Dutchman's-pipe or pipe vine (*A. durior*), native to rich woods in the eastern U.S. from Pennsylvania to Georgia and Alabama, is a vigorous climber, and it is widely planted in Europe and the U.S. as a porch vine. The flower is of an odd shape and bent like a pipe. About 12 other species are native to the U.S. Among the best known of these are the Virginia snakeroot (*A. serpentaria*), called also sangreeroot and serpentary, found in dry woods in the eastern U.S. and valued medicinally for its aromatic-stimulant root; the woolly pipe vine (*A. tomentosa*), native to woods from Indiana and Missouri southward; and the western Dutchman's-pipe (*A. californica*), native to California.

F. E. WESTLAKE

DUTCHMAN'S-PIPE (ARISTOLOCHIA DURIOR)

Among the various species grown in greenhouses are the remarkable pelican flower (*A. grandiflora*), a native of Jamaica, some varieties of which bear immense carrion-scented flowers 20 in. across with a taillike appendage 3 ft. long; and the showy calico flower (*A. elegans*), of Brazil, a graceful, free-blooming climber with solitary flowers having a yellow-green tube $1\frac{1}{2}$ in. long and a purple and white blotched limb 3 in. across. The tropical kinds are often called gooseflowers.

(N. TR.)

ARISTOMENES (according to one tradition 7th century B.C.) the hero of Messenian resistance to Sparta, may be a historical figure but has been heavily overlaid with legend. The standard version makes him leader of the rebellion of the 7th century B.C., the second Messenian War in which the poet Tyrtaeus took part on the Spartan side. After initial victories Aristomenes was betrayed by the Arcadian king Aristocrates at the battle of the Great Trench, and was besieged for many years in Eira in Messenia. This tradition probably goes back to the historian Callisthenes (4th century B.C.). The Cretan poet Rhianus (3rd century

B.C.) wrote an epic in six books, which apparently placed Aristomenes in a revolt of 490 B.C. and stressed his connection with Rhodes. The historian Myron of Priene (2nd century B.C.) connected him with the original Spartan conquest of Messenia in the 8th century. From these and other materials Pausanias compiled the longest surviving account, a story of the 7th-century rebellion with romantic embellishments drawn largely from Rhianus.

Pausanias records a tradition that Aristomenes' shield was dedicated in a temple at Lebadea, and used by Epaminondas at the battle of Leuctra. This may have been a popular story before the liberation of Messenia in 370, but that event gave a great impetus to the legend. Aristomenes' bones were brought from Rhodes to Messene, and heroic honours were paid to him for many centuries.

See, Pausanias iv; F. Jacoby, commentary to Rhianus in *Fragmente der griechischen Historiker* iii a. (1943). (A. As.)

ARISTOPHANES (*c.* 450–*c.* 388 B.C.), the most famous of all Greek writers of comedy. The little that is known of his life is derived mainly from Aristophanes' own words in the plays themselves, though a little outside information is to be had from the various hypotheses or arguments appended to these plays and stemming probably from a commentary or edition by the grammarian Symmachus (fl. *c.* A.D. 100). Aristophanes, son of Philippus, was an Athenian citizen belonging to the tribe named Pandionis, though he, or his father, seems to have owned some property on the island of Aegina. This fact is clear from his own words in the *Acharnes* (*The Acharnians;* lines 652–654); and it may be this which gave rise to certain unlikely, not to say absurd, accusations of foreign birth which seem to have been brought against him. He was born *c.* 450 B.C. (perhaps later) and must have died shortly after 388, the year in which his last play, *Ploutos* (or *Plutus;* "Wealth") was staged. Two posthumous comedies, *Aeolosicon* (probably a skit on Euripides' *Aeolus*) and *Kokalos* (or *Cocalus;* also, presumably, a mythological burlesque), were produced in or about the year 387 by his son, Araros. Aristophanes' dramatic activity covered the end of the period of Old and the start of that of the so-called Middle Comedy; and though the line of demarcation between these two is shadowy, it is not unreasonable to say that the first 10 of Aristophanes' 11 surviving plays belong to the Old and the last to the Middle. One of the indications of the change from Old to Middle Comedy being the dwindling importance of the chorus, it is worthy of note that whereas in the *Batrachoi* (*The Frogs;* 405 B.C.) the choric part still forms a fifth of the total number of lines, in the *Ecclesiazousai* (or *Ecclesiazusae; Ladies in Parliament;* 391 B.C.) it has shrunk to a mere twelfth, and in *Plutus* (388) has entirely disappeared, its place being taken by the performance of musical interludes.

Aristophanes' dramatic life covered about 40 years, and tradition ascribes to him a like number of comedies. (Some authorities, accepting a variant reading in the text of the *Suda Lexicon*, credit him with 44. In either case four of the total are generally attributed to Archippus, not Aristophanes.) The subject matter of these plays seems to have been highly diverse, and it is not easy to arrange even the extant plays, let alone those of which little is known except the titles, into anything approaching a satisfactory classification. (Little of any value has, in the case of Aristophanes, survived among papyrus finds, and most of the extant fragments are citations from lexicographers such as Photius and Hesychius, florilegists such as Stobaeus, grammarians such as Chaeroboscus, and literary antiquarians such as Athenaeus and Pollux. Of the 969 fragments that have been collected only four run to over ten lines; and many are no more than single words.) Roughly, however, the comedies may be divided into mythological burlesques and parodies; comedies of fancy; plays on social themes; war plays; and political plays.

Mythological Burlesques and Parodies.—These included the *Daedalos* (*Daedalus*) and the *Danaïdes* (*Danaïds*). There is no whole surviving play of this type, though many of the extant comedies contain much incidental parody, as did also many of those since lost.

Comedies of Fancy.—The only extant play of this type is the *Ornithes* (*The Birds;* 414 B.C.) with its Cloudcuckooborough or Land of Cockaigne setting—and even this seemingly fanciful play has by some scholars been accorded a political significance, being regarded as a satire on the imperialistic dreams of the city which had dispatched the ill-starred Sicilian expedition. The *Geras* (*Old Age* or *The Snakeskin*), with its chorus of rejuvenated old men, is lost.

Plays on Social Themes.—This is a numerous class and includes the *Nephelai* (*The Clouds*), the *Sphekes* (*The Wasps*), *The Frogs* and the *Ecclesiazusae*, all of which have survived complete.

The Clouds (423 B.C.) is an attack on "modern" education and morals, as imparted and taught by the sophists. In this play Socrates and his pupils are ridiculed, and at the end of it their school, the *Phrontisterion* or "Thinking Shop" is burned to the ground. Aristophanes' selection of Socrates as the typical sophist, Socrates being one of the sophists' most hostile and bitter critics, has long worried scholars. The most probable explanation is that the poet, who was in fact, as is known from Plato's *Symposium*, a personal friend of Socrates and not at all likely merely to have made a mistake, deliberately chose a man who, thanks to his odd looks and strange habits, was a figure much better known to the average Athenian than any of the genuine sophists.

The Wasps (422 B.C.) satirized the litigiousness of the Athenians in the person of the old juryman, Philocleon (*i.e.*, Love-Cleon), whose son, Bdelycleon (*i.e.*, Loathe-Cleon), arranges for his father to hold a "court" at home, where the first "case" to be heard is that of the house dog accused of the theft of a cheese, and so finally cures the father of his passion for the dicasteries (law courts).

The Frogs is a literary rather than a strictly "social" comedy. Dionysus, the god of drama, discontented with the poor quality of present-day tragedy, now that Euripides is dead, disguises himself as Hercules and goes down to Hades to bring back his favourite playwright to the land of the living. However, as the result of a competition which is arranged between Euripides and the elder poet, Aeschylus, Dionysus is won over from his old allegiance and returns to earth with the latter instead.

In the *Ecclesiazusae* the women of Athens are in power instead of the men. The plot introduces a communism of wealth, property and sex, which strongly recalls that discussed in the fifth book of Plato's *Republic*—so strongly, indeed, that one cannot help believing that in this play Aristophanes is parodying the philosopher's theories.

Of plays in this category only fragments of which have survived there may be mentioned (1) Aristophanes' earliest comedy *Daitales* (*The Banqueters*), which seems, like *The Clouds*, to have satirized modern educational and moral theories. It contained a "debate" between a good and a bad brother like that between the Just and Unjust Reason in the later play. (2) The *Heroes*, which apparently criticized adversely a modern tendency to neglect the old hero worship of Athens. (3) *Horai* (*The Seasons*), which dealt with the complementary theme of the growth and spread of new, mostly eastern, cults, among them that of the Thraco-Phrygian Sabazios, which is expelled from the city. (4) *Lemniai* (*The Women of Lemnos*), which satirized the immorality of the Athenian women. (5) *Gerytades* (*The Sweet Singer*), which was probably built on the same lines as *The Frogs* and depicted a similar attempt to recall older and better poets from the underworld.

War Plays.—About two-thirds of Aristophanes' dramatically active life was spent under the dark shadow of the Peloponnesian War, waged in the main between Athens and Sparta; and throughout this period the poet never ceased to use the theatre as a pulpit from which to preach his political doctrine of the criminal folly of war. *The Acharnians* (425 B.C.), his first extant play, deals with this subject. Its farmer-hero, Dicaeopolis, secures a private peace treaty for himself from the Spartans in spite of the violent opposition of the chorus of embittered and bellicose old charcoal burners of Acharnae. The play contains two harsh comic scenes set in Dicaepolis' private market: one in which a needy Megarian sells his own two daughters disguised as pigs rather than let them starve at home; and another in which a prosperous Boeotian, seeking a truly Athenian item, buys an informer. The *Eirene* (*Peace;* 421 B.C.), the title of which explains its theme, differs

from the earlier play in that it was staged seven months or so after the death in battle of Cleon and Brasidas, the two main champions of the war policy on the Athenian and Spartan sides respectively; indeed, only a few weeks, at most, could have elapsed after its production before the ratification of the peace of Nicias (? March 421 B.C.). Its main theme is the extraction of Peace from the cavern in which Zeus has allowed War to immure her.

The *Lysistrata* (411 B.C.), which was written not long after the Athenian disasters in Sicily and not long before the revolt of the Four Hundred, shows the seizure of the Acropolis and the treasury of Athens by the women who, at Lysistrata's instigation, have, together with all the women of Greece, declared a sex strike until such time as the men will make peace. The play is a strange mixture of humour, indecency, gravity and farce.

Of the plays in this category which have survived only in fragments may be mentioned (1) *Georgoi* (*The Farmers;* ? 424 B.C.), a comedy seemingly not unlike *Peace*, which also had a chorus of Attic farmers. There is indeed considerable confusion between the two plays, and it seems likely that one or two fragments sometimes attributed to a so-called second edition of *Peace* in fact come from *The Farmers.* (2) *Holkades* (*The Merchantmen*), described as a "peace play" in one of the arguments to *Peace*.

Political Plays.—These, as will be easily understood, are not easy to keep separate from the war plays, as, inevitably, during the last quarter of the 5th century B.C., politics meant foreign politics, and foreign politics meant but one thing: the question of continuing or stopping the Peloponnesian War. Aristophanes being a pacifist, in the sense that he was a convinced opponent of war, it was only to be expected that he should be "agin the government," so long as a series of bellicose politicians were in power. In all his earlier comedies, accordingly, there are assaults on the successive *Prostatai tou demou* (roughly, "prime ministers") from Pericles (whom he attacked posthumously) to Cleophon. As early as 426 B.C. the poet violently attacked in his *Babulonioi* (*Babylonians*) the regnant demagogue Cleon, and did not hesitate to criticize by implication the character of the Athenian empire by staging a chorus of Athenian "allies" shown as slaves of their master, the Athenian Demus. As this play was produced at the festival of the Great Dionysia, when deputies from those very "allied" cities were admitted among the audience, this piece of courage, or foolhardiness, involved its author in an impeachment at the hands of its chief victim. For the fact of this impeachment there is the word of the poet himself in the following year's play, *The Acharnians* (lines 377–382); though it is not known what form the case took. Aristophanes may have been tried for treason, or possibly "framed" by a *graphe xenias; i.e.*, an indictment on the score of foreign birth. But whatever the upshot, it may be supposed that the poet's punishment, if any, was light, for the production of the *Hippes* (*The Knights*) two years later shows that he had by no means learned his lesson. This play contains, or rather, is, a violent attack on the same demagogue, Cleon, who is depicted as the favourite slave of the stupid and irascible old man Demus, until he is at last ousted from his position of influence and authority by one Agoracritus, a sausage seller with even greater claims than himself to scoundrelism and impudence.

The Thesmophoriazusae and Plutus.—These two surviving comedies have been left out of this attempted classification. The *Thesmophoriazousai* (or *Thesmophoriazusae; Women Celebrating the Feast of Demeter;* 411 B.C.) is perhaps the funniest play that Aristophanes ever wrote. Its plot is as follows: Euripides has discovered that the women of Athens, angered by his constant attacks upon them in his tragedies, mean to discuss during their coming festival the question of compassing his death. Euripides calls on the effeminate Agathon, the tragic poet, to try and persuade him to plead his cause. Agathon refusing, Euripides gets his brother-in-law Mnesilochus to undertake the assignment. Mnesilochus is in consequence disguised (with great thoroughness) as a woman and sent on his mission. Unfortunately for him his true sex is discovered, and he is at once seized by the women. There follow three scenes in which he tries to escape; all three involve parodies of Euripides' tragedies, *Telephus*, *Palamedes* and (the extant) *Helen*, and all three attempts fail. Finally Euripides himself arrives and succeeds in rescuing his advocate by promising never again to revile women.

Plutus (*The God of Wealth*), a Middle Comedy (*see* above), will naturally not fit into the scheme. It is a somewhat drab play and does not enhance its author's reputation. The poor but honest Chremylus, on the advice of an oracle, pursues and possesses himself of a blind old man, who turns out to be none other than Plutus, god of wealth. Chremylus brings about the cure of his blindness, whereupon the god, his sight now restored, gives up his old and bad associates and begins to consort with worthy people who he can now see deserve his company and patronage. Three elucidatory, and not very interesting, scenes bring the play to an end.

Conclusion.—Aristophanes' reputation has stood the test of time, as witness the many modern translations of various of his plays and the frequent scenic and radio reproductions of them. When, however, we start to ask why the appeal of his comedies is still potent after the best part of two and a half millenniums—for comedy is as a rule a short-lived plant—it is not easy to give an answer. In the matter of plot construction Aristophanes' comedies leave much to be desired; they are often loosely put together and full of strange inconsequences, and, though in this matter the playwright was to a great extent at the mercy of tradition, the ends of most of his comedies degenerate into a series of disconnected and often somewhat boisterous and boring episodes. Nor can it be said that he is a good delineator of character; we look in vain in his plays for the equivalent of Falstaff or even of Dogberry or Sir Toby Belch. His personages are, when not, like George Bernard Shaw's, mere mouthpieces of their creator, little more than types. Where Aristophanes is great is in the wittiness of his dialogue, the keenness of his satire (good-humoured as a rule, though hardly so in the case of Euripides and certainly not in that of Cleon), the brilliance of his parody (particularly that of Euripides and especially in the *Thesmophoriazusae*), and perhaps above all in the ingenuity and invention of his comic scenes: Socrates suspended in his basket, Poseidon hiding from Zeus' observation under the umbrella, Trygaeus' ride to Heaven on his dung beetle, the trial of the dog Labes, Dionysus' bargaining with the corpse, and many more. And not the least claim on our admiration is that exacted by the beauty of some of his choral lyrics which, fresh and simple as they are, will be found by many readers as charming in their way as the more elaborate songs of the three great tragedians.

Where all is so excellent it is not easy to choose an example; but the *parodos* or entrance song of the chorus of *Clouds* in the play of that name (in B. B. Rogers' translation, pub. with the play by G. Bell & Sons, Ltd., London, 1916) is a typical specimen of the lyrics of Aristophanes at their best:

Clouds of all hue,
Rise we aloft with our garments of dew.
Come from old Ocean's unchangeable bed,
Come till the mountain's green summits we tread,
Come to the peaks with their landscapes untold,
Gaze on the Earth with her harvests of gold,
Gaze on the rivers in majesty streaming,
Gaze on the lordly, invincible Sea,
Come, for the Eye of the Ether is beaming,
Come, for all Nature is flashing and free.
Let us shake off this close-clinging dew
From our members eternally new,
And sail upwards the wide world to view.
Come away! Come away!

Come then with me,
Daughters of Mist, to the land of the free.
Come to the people whom Pallas hath blest,
Come to the soil where the Mysteries rest;
Come, where the glorified Temple invites
The pure to partake of its mystical rites:
Holy the gifts that are brought to the Gods,
Shrines with festoons and with garlands are crowned,
Pilgrims resort to the sacred abodes,
Gorgeous the festivals all the year round.
And the Bromian rejoicings in Spring,
When the flutes with their deep music ring,
And the sweetly-toned Choruses sing
Come away! Come away!

ARISTOPHANES OF BYZANTIUM (*c.* 257–180 B.C.), was a distinguished Greek literary critic and grammarian. He early removed to Alexandria, where he studied under leading scholars. He was appointed chief librarian there *c.* 195 B.C., and died *c.* 180 B.C. Aristophanes produced a text of Homer and also edited Hesiod's *Theogony,* Alcaeus, Pindar, Euripides, Aristophanes and perhaps Anacreon. Many of the *Arguments* prefixed in the manuscripts to Greek tragedies and comedies are ascribed to Aristophanes, and his study of Greek comedy led to separate works on Athenian courtesans and on character types. He revised and continued the *Pinakes* of Callimachus, a biographical history of Greek literature. As a lexicographer Aristophanes compiled collections of archaic and unusual words, of technical terms and of proverbs. As a grammarian Aristophanes founded a school and in his treatise *About Analogy* he laid down rules for declension, etc. In editing the lyric and dramatic poets he introduced innovations in metrical analysis and textual criticism which were widely adopted by later scholars. He was responsible for arranging Plato's dialogues in trilogies and is generally credited with the foundation of the so-called "Alexandrian Canon" (a selection in each genre of literary works which were considered models of excellence).

ARISTOTLE (384–322 B.C.), philosopher, psychologist, logician, moralist, political thinker, biologist, the founder of literary criticism, was born at Stagira, a Greek colonial town on the northwestern shores of the Aegean, in 384 B.C. He was the son of Nicomachus, a doctor belonging to the guild of the "sons of Aesculapius," who had acted as court physician to Amyntas II, the father of Philip of Macedon. We may perhaps attribute to this fact the interest which Aristotle afterward showed in physiological and zoological studies—though it must be admitted that these studies belong to his later years and were perhaps due less to early influence than to that general passion for detailed inquiry in every direction which marks the later stages of his development. Stagira had been largely colonized from the Ionic district of Chalcis in Euboea; Aristotle's mother was a native of that district; and to it he retired near the end of his life. His Ionic origin has been called in evidence to explain his interest in the facts of nature. It was the Ionian philosophers of Asia Minor who had first investigated "nature"; and Aristotle, it has been said, "was from first to last an Ionian, an observer of the facts of nature, a man for whom no problem was too detailed to whet his curiosity." But the development of Aristotle's thought probably would have led him to detailed scientific inquiry if he had been born an Athenian or a Theban.

ARISTOTLE. ROMAN SCULPTURE AFTER A GREEK ORIGINAL; IN THE SPADA GALLERY, ROME

Life of Aristotle.—The life of Aristotle falls into three clearly marked periods. First, there is the period of work in the philosophic school of Plato, the Academy at Athens, which covers the 20 years from the age of 17 to that of 37 (367–347 B.C.) and only comes to an end with the death of Plato. Next, there is the period of his *Wanderjahre*—at Assus, in the south of the Troad; on the island of Lesbos opposite; and at the Macedonian court in Pella, about 80 mi. to the west of Stagira—which covers the dozen years from the age of 37 to that of 49 (347–335 B.C.) and ends with the majority and accession of his pupil Alexander. Finally, there is a second period of work in Athens—a period of work on his own account as the head of the Peripatetic school in the Lyceum—which covers, roughly, another dozen years of his life, from the age of 49 to that of 62 (335–322 B.C.), and ends with his retirement to Chalcis and his death. These periods are not only stages in the external course of a life; they are also—it has been contended by W. Jaeger in his work on Aristotle—stages in the internal development of a body of thought.

The Aristotle of the first period differs from the Aristotle of the last; and it is thus of the first importance to follow the stages of his life in order to understand the stages, and the progress, of the development of his thought.

1. It must have been the greatest and the profoundest of factors in the life of Aristotle that he worked for 20 years by the side of Plato. He came as a disciple—a young disciple of 17—to sit at the feet of a master who had attained the age of 60; but in the course of time he must have become a fellow worker in the studies of the Academy. The Plato of those years—the gray-haired Plato in the evening of a life which reached 81—was no longer the Plato of the *Republic;* but he was more than ever the beloved master of a body of "friends" engaged in the pursuit of truth and goodness. His school was now in the stage which is marked by the *Theaetetus,* the *Politicus* and the other dialogues of this period: it had left the Socratic stage and was occupied with the problem of "ideas" and with the division of "ideas," down and down, until the indivisible (or final unit of division, by which Plato meant the *infima species*) was eventually reached. Here was the germ from which grew Aristotle's logic and from which, again, his metaphysics took its beginning. But the Academy was also engaged in some measure of concrete and scientific study. Mathematics and astronomy were especially cultivated: the *Laws* of Plato, the work of his old age, presupposes a body of research in legal and constitutional questions; and the study of medicine seems also to have been in some measure pursued. We may guess that Aristotle took his part in these various studies. His sketch of an ideal state in the last two books of the *Politics* shows a study of, and is partly based on, Plato's *Laws.* He hardly shared, indeed, in Plato's passion for mathematics; and he was perhaps always more interested than Plato in biological study. Some scholars have drawn a distinction between Plato the mathematician and Aristotle the biologist. There is some truth in the distinction. Plato's interest in "ideas" found a natural basis in geometrical forms and the abstract rules of numbers; Aristotle's interest in the classification of genera and species led him naturally toward the world of organic nature, and the emphasis which he came to place on development (*genesis*) accentuated that tendency. Yet it may be contended that the mathematical knowledge of Plato went little

deeper than that of Aristotle; and on the other hand it is easy to exaggerate the importance of the biological element in Aristotle's general system of thought. What seems certain is that there is no proof of any serious division of opinion between Aristotle and Plato during the 20 years of their intercourse.

Aristotle remained one of the circle of "friends" in the Academy throughout that period; he joined in its researches and possibly its teaching[1]; and the dialogues which he wrote during those years —dialogues now lost, but celebrated in antiquity alike for their style and their content—were modeled largely on the style of the later series of Platonic dialogues which begins with the *Theaetetus*. We may admit, indeed, that in his later dialogues, and particularly in that entitled *De philosophia*, he diverged from the Platonic doctrine of "ideas" as "separable" from and existing "beyond" individual things; but there is no reason for thinking that this divergence ever approached the nature of a sharp contention or was anything more than a friendly difference of opinion.

The master and the pupil were undivided when Plato died in 347; and the noble words which Aristotle wrote for an altar of friendship in memory of Plato attest the depth of the pupil's feeling even after the master's death.

2. On Plato's death his nephew Speusippus became the head of the Academy. Aristotle and another of Plato's pupils, Xenocrates, thereupon left Athens, perhaps believing, as Jaeger suggests, that Speusippus was the heir not of the spirit, but only of the office of the master, and perhaps desiring to find a new place for the habitation of the spirit. They chose Assus for interesting reasons. Two old pupils of Plato, Erastus and Coriscus, had taken his teaching back to their native town of Scepsis, on the slopes of Mt. Ida. There they had come in contact with Hermias, a eunuch, who had perhaps been a banker's clerk and had thrived sufficiently to buy mining property near Mt. Ida and eventually to acquire the title of prince from the Persians and establish himself as "tyrant" in Atarneus, a town to the southeast of Assus. The two Platonists and Hermias had studied together. Plato had written to them the sixth of his *Epistles* for their guidance; and Hermias, some time before the death of Plato, had given the town of Assus in gratitude to his two companions in study. To Assus, in this conjuncture of affairs, Aristotle and his fellow pupil came in order to join the Platonic circle; and there Aristotle set up a school in which he taught for the next three years. Hermias was among his pupils; and Theophrastus came from the neighbouring island of Lesbos to join the company. Two consequences followed. In the first place, Hermias gave his adopted daughter (who was also his niece) in marriage to Aristotle. In the second place, perhaps on the suggestion of Theophrastus, Aristotle moved, about 344 B.C., to the island of Lesbos, and there he spent two years (344–342 B.C.) largely in the study of natural history, especially marine biology. But politics, as they had been present in his thought and probably in his teaching from his first coming to Assus and joining the company of Hermias (we may attribute the germ of the *Politics* to this date), continued to be present and pressing while he was at work in Lesbos. Hermias seems to have been negotiating about this time with Philip of Macedon, who was already thinking of the expedition against Persia and might naturally desire a foothold on the south of the Dardanelles in the territory of the "tyrant" of Atarneus. It may have been in this way and in consequence of these negotiations that Aristotle, the son-in-law of Hermias, was invited by Philip to come to Pella and continue his teaching there for the benefit of the young Alexander. In 342 he accepted the invitation; and the next seven years of his life (342–335 B.C.) were spent in Macedonia. He had scarcely settled in Pella when he heard the news that Hermias had been seized by the Persians, taken to Susa, tortured and crucified, with the final words on his lips, "Tell my friends and companions that I have done nothing unworthy of philosophy." The news may have helped to inspire Aristotle (who wrote an ode celebrating Hermias, along with Achilles, as a follower of true valour) with anti-Persian feeling; and it may conceivably have led him to inspire his pupil to follow the way of Achilles[2] and, as the champion and leader of a united Greece, to lay low the great king of the east. Unfortunately, there is little evidence which bears on Aristotle's work and teaching in Macedonia. Possibly he had a little circle of "friends" (including Theophrastus) with whom he continued his general studies and teaching. It is known that he formed a friendship with Antipater, and this friendship was one of the chief factors in the last phase of his life.

3. Even before the death of Philip in 336 Alexander was more and more concerned in affairs, and Aristotle must have seen less of his pupil. After the accession of Alexander there was nothing to keep him in Macedonia, and he naturally returned to Athens, the intellectual centre of Greece, consecrated for him by the memory of Plato, where he could hope to work quietly under the protection of Antipater, now acting as regent in Macedonia and Greece after the departure of Alexander on his eastern campaign. His relations with Alexander now were practically at an end. True, his nephew Callisthenes accompanied Alexander to the east; true, he received scientific material from the scientific staff which accompanied the eastern expedition; true, again, he wrote a treatise *Alexander, or On Colonies*, which seems to belong to the period of Alexander's foundation of colonial cities in Egypt and Asia. But Callisthenes was done to death by Alexander in 327; and even before that time Alexander had already departed widely from Aristotle's teaching and had deserted anti-Persian feeling and notions of Greek supremacy for the plan of an empire resting on the equal and harmonious co-operation of Persians and Greeks. In any case the Aristotle of the last 13 years (335–322 B.C.) is an Aristotle immersed in pure science and investigation. Side by side with the Academy (now under Xenocrates, the fellow pupil of Plato who had once followed him to Assus) he set up his own school in the Lyceum—a school which came to be known as the Peripatetic, from the *peripatos* or "walk" in its garden in which he walked and talked with his pupils. The school was a definite organization (*thiasos*), somewhat like a college, which formed a society devoted to the cult of the Muses; and like a college it had its regular dinners and even its plate. It was furnished with maps and a library, it had something of a staff, and Theophrastus was among its lecturers. The great body of the extant Aristotelian treatises represents the lectures which Aristotle delivered in his school at Athens in the evening of his life—not that they were then all composed for the first time (on the contrary, they may have grown during the years of wandering, and the extant forms may perhaps contain traces of earlier versions and views); rather they were now reduced by Aristotle to the form in which we know them. The range of studies was catholic and indeed universal. It is now that Aristotle departs from his master Plato—not so much in altering his theory of "ideas" as in shifting the whole balance of his interest and in turning from "the heavenly things that are the objects of the higher philosophy" to the detailed facts of historical and biological process. He leaves "philosophy," it may be said, for "history," in that wide sense of the word in which it means the sober registering of recorded fact; and here he shows himself more Baconian than the Bacon of the *Novum Organum*. The work of his last years is an encyclopaedia—an encyclopaedia of unique value, in that it proceeds from a single mind informed by a single set of controlling ideas. In the field of human history he produced, on the one side, lists of the victors in the Pythian and Olympic games and a chronology of the Athenian drama (which supplemented the *Poetics*); on the other, a record of 158 constitutions (which equally supplemented the *Politics*), an account of "the customs of barbarians" and a treatise on "cases of constitutional law." In the field of natural history the volume of his production was greater still. It included the *Historia Animalium*, a record of biological facts, in which the material furnished by Alexander's expedition seems to have been used (as it also seems to have been used in a treatise "on the rising of the Nile"); it included biological treatises based on these facts; it included a body of treatises which inaugurated the study of psychology; and it has been suggested that it also included both a scheme for the

[1]Rhetoric was possibly the subject of his lectures; and we may perhaps date the beginning of the *Rhetoric* in this period.

[2]One of the first acts of Alexander, after crossing the Dardanelles, was to place a garland on the tomb of Achilles.

history of the sciences (physics—including metaphysics—mathematics and medicine) and researches in medical subjects such as anatomy and physiology.

In 323, in the midst of all these activities, Aristotle received the news of the death of Alexander. Antipater had been summoned to the presence of Alexander and was absent from Greece; a nationalist party raised its head in Athens; and Aristotle fled to his mother's home in Chalcis, on the island of Euboea, where he died in 322 at the age of 62.[1] By his marriage with the adopted daughter of Hermias he had a daughter, called Pythias; by a later union he had a son, called according to Greek custom by the name of his grandfather Nicomachus.

Aristotle's personality is hidden behind his works. Tradition makes him speak with a lisp and pay attention to dress. The busts, which seem to be authentic, show firm lips and intent eyes. He was a man of affairs, versed in the ways of courts; and he had at its height the invincible and insatiable curiosity of the Greek mind. But there was something more in him than the light of a pure intellect. The study of his life leaves the impression of generous humanity. His will shows him concerned for every relative and dependent, not least for the emancipation of his slaves. And there is a phrase in an Aristotelian fragment, which may come from a letter of his later years, which cannot be forgotten: "The more I find myself by myself and alone, the more I have become a lover of myth." "Myth" may have meant to Aristotle a little of what revelation has meant to millions in later centuries; and for all his scientific labours he may yet have felt at the last—what indeed he suggests in passages of his own treatises—that there was a supreme consolation in the life of contemplation which might lead, at its highest moments, to visions of the divine.

The Writings of Aristotle.—The writings of Aristotle fall into three main kinds. There are literary essays intended for publication, such as the early dialogues (now lost except for fragments); there are the set works of his later years, such as the *Constitution of Athens* (*q.v.*; from his record of 158 constitutions); and above all there are what may be called treatises, intended for use in lectures or for the reading of the students of the Lyceum, of which there are a large variety.

1. The dialogues, written with a conscious art and a definite pursuit of style, were modeled on those of Plato; but they are said by ancient writers to have differed from Plato's dialogues in representing different persons as stating at length their different views on the subject treated. They were famed for their lucidity and the easy flow of their style; they belong to the period of Aristotle's discipleship in the Academy (367–347 B.C.); almost to the very last they followed the doctrine of Plato; and their clear and stirring account of Platonic doctrine exercised a large influence in antiquity down to the days of St. Augustine. The two most famous and considerable of these dialogues were (*a*) the *Protrepticus*, an exhortation to the philosophic life, which was a model for Cicero's *Hortensius* and was partly incorporated by Iamblichus (as Ingram Bywater first recognized in 1869) in a philosophic textbook for beginners, also called the *Protrepticus;* and (*b*) the *De philosophia*, perhaps the latest of all the dialogues, in which, as we have already seen, Aristotle first showed signs of a movement away from Plato's theory of "ideas." Generally, however, the dialogues of Aristotle were purely Platonic in the range and in the substance of their thought; and several of them, such as the *Politicus* and the *Sophistes*, bore the same name and perhaps handled the same theme as Platonic dialogues. If only we could recover the lost dialogue "On Justice," which appears from its title to correspond to Plato's *Republic* (for the *Republic*, too, treats of justice, and indeed its alternative title is "On Justice"), it would be interesting to compare Aristotle's views in this dialogue both with those of his master and with his own later views on the doctrines of the *Republic* as they are expressed in the second book of the *Politics*.

2. Midway between the dialogues and the treatises of Aristotle come a number of works which, like the dialogues, were set compositions in literary form intended for publication, but which, like the treatises, were mainly of the nature of scientific compilations. Apart from an essay *On Monarchy*, which may belong to the time of his residence at Pella, these works belong to the third and last period of his life, during which he was occupied in investigation and teaching in the Lyceum. They include the *Alexander, or On Colonies;* the accounts of 158 constitutions; the compilations of *The Customs of Barbarians* and of *Cases of Constitutional Law;* the chronological tables of victors in the Pythian and Olympic games; and a list of the successful dramas produced at the festivals of Dionysus at Athens.

3. The treatises, as we have seen, may possibly have been begun during the *Wanderjahre* from 347 to 335, but in the form in which they have come down to us they belong to the final period between 335 and 322. They were all written by Aristotle in connection with his courses of lectures—not so much, probably, in the way of "notes" to be followed in the delivery of lectures (the actual lectures may have been more discursive and more of the nature of discussions or conversations with a class) as in the way of "memoranda," which may have been written afterward, to preserve a record of the main results attained in lectures and discussions.

The treatises may be grouped under some eight main heads, though we cannot for a moment say that each of these heads corresponds to a separate "course" of lectures, or that the classification is the same as Aristotle himself would have made. The first head is what Aristotle calls "analytics," or, as we should say, logic. Under this head there are half a dozen treatises (the *Categories*, the *De interpretatione*, the *Topics*, the *Sophistici Elenchi* and the *Prior* and *Posterior Analytics*) which came to be known, centuries afterward, as the *Organon*, or "instrument" of science and scientific reasoning. The second head we may call by the name of "physics," using that term in a wider sense than that in which we use it today and taking it to mean the general study of inorganic "nature" (*physis*). Here we have to reckon the treatise on *Physics*, the *De caelo*, the *De generatione et corruptione* and the *Meteorologica*. The third head may be termed psychology—of which (as also of logic) Aristotle was the inventor. Under it fall the *De anima* and the *Parva naturalia*—the latter a collection of essays on subjects such as sensation, memory, sleep and dreams. The fourth head may be called by the name of biology. We have seen that Aristotle was interested in the study of this subject as early as 344–342 B.C., and that he continued his interest and extended his studies in the final period of his life. His biological treatises are the *Historia animalium* (a record of data corresponding, in the sphere of natural history, to the record of 158 constitutions in the sphere of politics) and a number of theoretical works, based on the data of the *Historia*, which include studies of the "parts," the "progression," the "motion" and the "reproduction" of animals. It was indeed, in the sphere of biology that Aristotle made one of his greatest contributions to the advancement of learning.

The remaining heads under which his treatises may be grouped are the metaphysical, the ethical, the political and the literary. Under the head of metaphysics, or "first philosophy," which is an inquiry into the nature of existence (*ousia*) and involves a discussion of the question whether universals exist as substances "separable" from their particulars, we have a composite treatise, containing different strata put together by later editors, which is called the *Metaphysics*. Under the head of ethics there are two treatises—the *Eudemian Ethics* (so called from Eudemus, one of Aristotle's pupils) and the *Nicomachean Ethics* (which derives its name from his son Nicomachus). It is now held that the former is a genuine work of Aristotle, belonging to the middle period of his life and was subsequently edited by Eudemus; and that the latter is a statement, edited by his son, of his final views on ethics

[1] An archaeological discovery, which may bear on Aristotle, was made about 1890. Near Eretria, in Euboea, in an ancient cemetery in which nonresidents as well as residents had been buried, there was exhumed from a rich tomb with marble foundations a number of objects—seven gold diadems, two styluses, a pen, a signet ring and a terra-cotta statuette of a man in an attitude like that which Christodorus (*Anthologia Palatina*, ii) ascribes to a statue of Aristotle. On a sepulchral stone in the grave was found the inscription, in lettering of the early 3rd century B.C., [B]ιοτη [A]ριστοτελου ("Life of Aristotle"). The grave may have been connected with the family of Aristotle (though Chalcis is over a dozen miles away from Eretria); the styluses, pen and statuette may, in that case, be connected with Aristotle himself; and a skull which was also discovered may have been his. (See *Corpus Inscriptionum Graecarum*, vol. xii, fasc. ix, under "Eretria," where references are given to the literature on the subject.)

in the last period of his life. (However, even the *Nicomachean Ethics* is somewhat simple, not to say elementary, in its psychological foundations and shows little connection with the detailed study of the problems of psychology in the treatises which deal with that subject.) Under the head of politics there is the treatise called the *Politics,* which falls into three parts—a philosophical "theory of the state" in books i–iii; a detailed study (running into practical suggestions) of the "forms and methods of government" in books iv–vi; and a torso of a sketch of an ideal state in books vii–viii. Opinions differ in regard to the dates of the different parts; but it has been suggested that the last two books, which show a considerable dependence on Plato's *Laws,* are early and that the three middle books, which go naturally with the collection of 158 constitutions and suggest in their method the biological studies of Aristotle's last period, are of a later date. Finally, we have to count, under the head of literary criticism, the three books of the *Rhetoric* and the short treatise called the *Poetics.*

More important than the classification of Aristotle's treatises is the chronology of their composition, although as it is, it must also remain conjectural. We are justified, however, in saying that Aristotle seems to have moved from an earlier concern with logic and "the higher philosophy of heavenly things" (or, in other words, from the circle of Platonic interests) toward a later and more absorbing passion for the study and record of actual facts alike in the world of "nature" and in the world of political and literary "art." On this basis some would assign the first form of a number of treatises (which, it is true, must have been expanded later in connection with Aristotle's later lectures) to the period before 335. Among these may have been the *Organon,* the *Physics,* the third (and most general) book of the *De anima,* the *Eudemian Ethics,* a considerable part of the *Metaphysics* and some parts of the *Politics.* The rest of the treatises may be ascribed to the final period of Aristotle's life. But such speculations in the chronology of his writings are at best conjectural.

The Philosophy of Aristotle.—It is impossible, within the space of this brief article, to give any account of Aristotle's teaching on the many specific branches of knowledge with which he dealt. (*See* rather such articles as LOGIC, HISTORY OF; ETHICS, HISTORY OF; and KNOWLEDGE, THEORY OF.) Here we can only deal with the general development of Aristotle's thought, the general views which run through his treatises and the particular opinions which have influenced subsequent thought most profoundly. Starting with a veneration for Plato and an acceptance of the Platonic tradition which lasted almost to the death of Plato and his own middle age, he followed even more in the last 25 years of his life (347–322 B.C.) a peculiar and distinctive method of his own. Plato had studied reality as a whole; and the reality that he had studied had been the suprasensible reality of "ideas." Aristotle divided reality into the several spheres of physics, biology, ethics, politics and psychology; and the reality that he studied in these spheres was constituted by the observable facts of actual and concrete individual substances. The essence of his procedure in each field of inquiry was observation of the data (coupled, in biology at any rate, with experimental research in the way of dissection, with a view to determining the data more exactly); and the object of his study was to discover some general theory which, in the Greek phrase, "saved"—or, as we might say, explained without doing violence to them—the data which had been observed. ("The course of exposition," he says in the *De partibus animalium,* "must be, first, to state the attributes common to whole groups of animals, and then to attempt to give their explanation.") Aristotle possessed in a remarkable degree the scientific habit of mind. On the one hand he distinguished the various "sciences" (or, as he would have preferred to say, "inquiries"), drawing the lines of division between them and attaching to some of them the names that they have since continued to bear; on the other hand he followed a scientific procedure in each of the subjects treated and, within the limits of his technique (he had few instruments at his disposal and he had to discover for himself the rules of reasoning), observed the permanent canons of scientific inquiry. If the essence of his method and teaching had been followed, the fruit would have been a great period of scientific investigation and discovery. No nobler exordium to such a period could be furnished than the great passage in the *De partibus animalium* (642b, 22 ff.), in which he propounds the program and the justification of a study of nature. But the essence of his teaching and method was not followed. The reason may partly be that his treatises seem to have been submerged for more than 200 years following his death. According to a tradition of antiquity which may well be accepted, the library and the treatises of Aristotle passed at his death to Neleus, the son of that Coriscus of Scepsis whom he had left Athens to join in 347 B.C.; and they continued in the hands of the descendants of Neleus, apparently neglected and forgotten, until they were recovered for the learned world from the cellar of a house in Scepsis in the time of Sulla (80 B.C.). Destitute of the master's treatises and rapidly forgetting his spirit, the Peripatetic school hardened into a logical tradition of its own; and even when the treatises were recovered, they were treated not as incentives to inquiry and further discovery but as a rounded body of complete knowledge (perhaps the last thing that Aristotle would have claimed for his tentative conclusions), on which commentators might write and lecture as if it contained the final word of perfection. As a spirit and an incentive, Aristotle was dead; he only remained as "the master of those who know" and a *corpus scientiae.* In this way the great researcher was made the enemy of research; and this continued to be his fate for centuries. The middle ages, as we shall see, inherited the Peripatetic cult of "the master"; they "made his torch," as Dryden said, "their universal light"; and thus the beginning of modern science in the 16th century took the form of a revolt against Aristotle—one of the most scientific spirits that ever lived.

Aristotle had a profound respect for given facts and a deep passion for classifying these facts with a scrupulous respect for their exact character. He was no longer, when he reached the definitely scientific stage of his development, interested in "ideas" as they were conceived by Plato; but he was profoundly interested in "forms"—in the common attributes which can be observed in the same kind of things and enable us to classify such things in terms of genera and species. "The principal object of natural philosophy," he wrote, "is not the material elements, but their composition and the totality of the form." The aim of all science, we may say, is to form an intelligible universe by discovering the universal in the particulars—particulars which are the primary and only substances or existences, but which none the less have no existence independently of the universal which is their "form" and makes them the class or kind of existence which they are. Such universals are concepts formed by the intuitive reason on the basis of repeated "sensations," which rise to "memory" and then to "experience" of the same kind of thing. By making such concepts we make a world we can understand—the world of knowledge; and within that world we can reason and use the methods of valid argument.

It is one of the greatest services of Aristotle to knowledge that he laid down these methods, that he was the first to do so, and that he invented the science of logic. There was reasoning before Aristotle, and the dialogues of Plato abundantly imply its methods and rules. But Aristotle was the first to make them explicit; and the inventor of the syllogism, as he may justly be called, deserves to be celebrated in the annals of human thought.

One of the general views which runs through Aristotle's thought, if it is expressed more particularly in the *Physics,* is a view which we may call by the name of evolution or *genesis.* Whether this view was a result of study of biology, or his study of biology was a result and an application of a general view which he had formed on general grounds, we cannot pause to inquire. In any case, a pervading conception of growth is what chiefly distinguishes his thought from that of Plato. Plato had been more deeply interested in being than in becoming, which belonged in his view to the deceptive world of fallible sense; and he had tried to interpret true and permanent being in the light of the permanent truths of mathematics, making number the basis of the universe and identifying matter with space. His universe was thus a static universe.

The universe of Aristotle is dynamic; his world is engaged in becoming; the "nature" of each thing is a potentiality which

moves through a process of development (a process which is also "nature") to an actuality which is true and final and perfect "nature"—for "nature is the end," as he writes in the *Politics*, "and what each thing is when fully developed we call its nature." There is thus a teleological view behind Aristotle's conception of the nature of things. The movement which he sees incessantly at work is a movement toward an end immanent from the first in the subject of movement and determining all its growth; "for the process of evolution is for the sake of the thing finally evolved, and not this for the sake of the process." This general conception is applied by Aristotle not only to developments in the sphere of organic nature, but also to constructions in the sphere of human art. The activity of man, alike in the building of a house and in the making of a statue, in the putting together of a state and in the composition of a tragedy, is the activity of realizing a plan or "form" and of causing a material which has the proper potentiality—be it wood and stone, or marble, or the human trend to association, or the human passion for imitation—to move toward the "form" which is also its "end." There is thus no distinction between "nature" and "art" in Aristotle's view. They move on parallel lines; they may co-operate. As he says of the state in the *Politics*, "by nature there is an impulse in all men toward political association, but he who first put them together was the cause of the greatest of benefits."

Of all Aristotle's treatises it is perhaps those on ethics and on politics (along with that on logic) which have exercised the deepest and most continuous influence on subsequent thought. There have been many who, like Archbishop Laud (St. Thomas Aquinas and Dante might equally have made the confession), have acknowledged Aristotle as their "master *in humanis*." The *Nicomachean Ethics* is one of the great books of the world. Its application of the doctrine of the mean to the various virtues; its theory of the relation between external goods and the inward happiness of the spirit; its doctrine of habit and of the importance of the stage of habituation in moral development—all these are among the permanent possessions of human thought. We may reckon in the same class what Aristotle says of the life of contemplation (which is "a laying hold on immortality as far as is possible for men") and what he writes of the connection between "leisure" (an activity to be distinguished alike from "work" and from "amusement") and the contemplative life. The *Politics*, if it has not all the qualities of the *Ethics*, has furnished the generations with many of the great axioms of political truth. That "the state is by nature" (which does not prevent it from also being "by art"); that it exists for the good life, if it begins for the sake of life only; that law is the true sovereign of states, and governments are servants of law; that there is a fundamental difference between the lawful monarch and the tyrant who governs by his arbitrary will; that there is a right inherent in the people, in virtue of their capacity of collective judgment, to elect their rulers and call them to account—these are some of the axioms on which men have argued from century to century. Here, and in this example, we can see a service which Aristotle—schematized and glossed and ossified as he might be in the teaching of the schools—nonetheless continued to render for generations. He supplied the great "topics" of thought—the themes for discussion and the standard "commonplaces" on these themes; and he supplied, too, a terminology in the grooves of which thought could run. When thought had to be rebuilt after the collapse of classical civilization and while the middle ages were toiling at the work, it was no small thing that men should have the tools of a terminology and the rules of accepted axioms.

The History of Aristotle's Writings and Philosophy.—The tradition of Aristotle was continued—and forgotten, perhaps, even more than it was continued—in the Peripatetic school. But it never affected classical antiquity so deeply as the tradition of Plato, which—whether it was fused, as by Posidonius of Apamea, into an eclectic philosophy which also included Stoic theory, or was exaggerated, as it was by the Neoplatonists, into a sort of mysticism—continued to be a magnet to ancient thought. It is in the period between the collapse of ancient civilization in the 5th century A.D. and the beginning of the classical Renaissance in the 15th that the influence of Aristotle is strongest and most diffused. It was the logic of Aristotle which for more than half of this period (from 500 to 1200) was alone known in the west; and not only so, but down to the beginning of the 12th century it was only the earlier and more elementary parts of the *Organon* which were known and studied. Even this was only studied in a Latin translation and commentary made by Boethius; and indeed the study of Aristotle through the whole of the middle ages was the study of Aristotle in a Latin version, not in the original Greek. But the Latin version of the first half of the *Organon* was nonetheless a considerable instrument of education for many centuries. It was the staple of dialectic, one of the three subjects of the medieval trivium; and as dialectic was the subject of all others which set students effectively thinking, we may say that Aristotle was in this way the chief influence, outside theology, in the educational system of the early middle ages. His logical treatises were studied in the chapter schools attached to cathedrals and in the schools of the Benedictine monasteries; and along with grammar and rhetoric, the other two subjects of the trivium, they were the discipline of thousands of students.

A new epoch begins in the 12th century. In the first place, the methods of dialectic, no longer studied merely as a discipline in schools, begin to be applied to problems of theology; for already Berenger of Tours in the 11th century had brought Aristotelian logic to bear on the problem of transubstantiation. The application of logic to theology became still more evident when Roscelin, Guillaume de Champeaux and, above all, Abelard began to ventilate theories about the nature of universals and to draw their theories to theological consequences. The old difference between Platonic "ideas" and Aristotelian "forms" re-emerged in the field of theology; and conceptions of the nature of God were made to depend on the difference. In the second place, about 1130, the whole of the *Organon* became known to the west and began to be studied there, and before the middle of the 12th century Otto of Freising had come to Paris, as he tells, to study the subtleties of Aristotelian logic in the later and profounder *Analytics* as well as in the earlier treatises of the *Organon*. Finally, about 1170, the University of Paris came into existence as an organized body; and with the foundation of the medieval university the great cadre was provided in which the whole body of Aristotelian writings might find a place and in which, as soon as they had found their place, the great attempt might be made—the attempt which we call scholasticism—to reconcile their tenets and their secular wisdom with the revelation of the Bible and the divine wisdom of the fathers of the church.

Between 1200 and 1270, the general body of the Aristotelian writings other than the *Organon* (the *Physics*, the *Metaphysics* and the *De anima;* the *Politics* and the *Ethics*) began to be imported into the University of Paris, the University of Oxford, which had arisen at the same time, and the University of Cambridge, which had arisen a little later. It was from Córdoba and Constantinople that the new knowledge of the works of Aristotle was derived; and the process of the transmission of his various writings to the Latin west is one of the curiosities of the history of learning.

Córdoba in the 12th century was the great seat of Arabic learning. Arabic learning had included, after about A.D. 800, the study of the Aristotelian treatises and especially of those which dealt with physics, metaphysics and psychology. The tradition of Aristotle had survived among the Syrians, and the Arabs had acquired it when they conquered Syria in the 7th century. Great Aristotelian commentators had arisen among the Arabs—especially Avicenna (*q.v.*), who lived in the east and died at Hamadan in 1037, and Averroës (*q.v.*), who lived in Arabic Spain and died at Córdoba in 1198. The Arabic paraphrases and commentaries began to penetrate into the Latin west after 1200, partly across the Pyrenees and partly by way of Palermo, the half-Arabic capital of Sicily, in which the emperor Frederick II was a patron of science and literature. They came in a curious form—the form of Latin translations (which sometimes sank to the level of transliterations and sometimes were not even made directly, but only from an intervening Hebrew version) of Arabic exegesis, which itself was not based on the original Greek, but rested on Arabic versions of

Aristotle, which might rest in turn on Syriac versions of the original text. Not only did they come in a curious form, but they also brought curious views of Aristotle's doctrines, which had suffered a change in the course of their wanderings; and Aristotle would hardly have recognized as his own the idea, which the Arabs had extracted from the *De anima*, that the mortal soul of man was reabsorbed at death into the universal creative soul of the universe. With their curious form and their dubious views the Aristotelian treatises which the west received from the Arabs were at first suspect; their study was at one time prohibited by the church, which frowned on the *fisica et metafisica;* but they won their way and established their place in study. A school of "Averroists," which lasted until the 16th century, drew its inspiration from these writings. (*See* AVERROISM, LATIN.)

Constantinople supplied the west with a more sober and recognizable Aristotle. All through its history, from the time of Justinian onward, the scholars of the city had pursued the study of Aristotelian philosophy; and toward the reign of Alexius Comnenus, about A.D. 1100, we find Michael of Ephesus lecturing in the school of philosophy (which had been recently refounded by the empire and of which the great scholar Psellus had been the head) on the physics and metaphysics, and also the ethics and politics of Aristotle. When the city was captured by the Latins during the fourth crusade (1204) Latin clergy settled in the Byzantine empire. They learned Greek: they found Greek manuscripts; and two of them (both Dominicans), William of Moerbecke in Flanders and Henry of Brabant, translated, under the impulse of the great Dominican scholar St. Thomas and in collaboration with him, many of the writings of Aristotle (1260–70): It was mainly in this way that St. Thomas learned the Aristotle on whom he wrote commentaries and whose views he sought to co-ordinate with Christian revelation in the great edifice of his *Summa*.

In the writings of St. Thomas, Aristotle the encyclopaedist, 1,600 years after his death, was wrought upon by another great and massive encyclopaedist, who sought to inform the sum of ancient knowledge with the spirit of Christian faith; and the pagan scholar, who had built his own great monument, was incorporated by a Christian thinker into another of the great and enduring monuments of human knowledge.

By 1300 Aristotle was the acknowledged "master of those who know." For Dante, indeed, he was "the philosopher": his views run through the *De monarchia,* appear in the exegesis of the poems of the *Vita nuova* and are part of the texture and framework of the *Divina commedia*. The empire of Aristotle lasted for two centuries. It passed with the Italian Renaissance, which was Platonic rather than Aristotelian; it passed with the German Reformation, which, through Luther, denounced the "Aristotelianism" of the schoolmen; it passed with the beginnings of modern science, which, seeking to escape from the medieval tradition and dogma, in which Aristotle had been incorporated, left Aristotle, neglecting the deep and genuine science of his writings because it had been yoked with what they sought to escape. Only in the latter part of the 19th century, with the development of biological study, did Aristotle the scientist—the student of biology and the prophet of growth—come to be recognized once more, and only in the 20th century did the development of his mind and the growth of his philosophy of nature begin to be understood in terms of his own doctrine of "evolution."

See also references under "Aristotle" in the Index.

BIBLIOGRAPHY.—For Aristotle's works in Greek, there is the edition by the Royal Prussian academy, *Aristotelis opera*, 5 vol. (1831–70), which includes an excellent *Index Aristotelicus*. There are also editions of a number of his works in the "Teubner Series" of texts. There is a complete English translation of *The Works of Aristotle,* ed. by J. A. Smith and by W. D. Ross, 12 vol. (1908–52), as well as a volume of *Selections* in English ed. by W. D. Ross (1928). The Greek commentaries have likewise been published by the Royal Prussian academy, *Commentaria in Aristotelem Graeca,* 23 vol. (1882–1909), with a *Supplementum Aristotelicum*, 3 vol. (1885–1903).

Among modern editions of separate works the following may be mentioned For logic. T. Waitz, *Organon* (1844–46); W. D. Ross, *Prior and Posterior Analytics*, text and commentary (1949); L. Minio Paluello, *Categories* and *De interpretatione*, text (1949). For the *Ethics* and the political writings: J. Burnet, *Ethics* (1906); H. H. Joachim, *Ethics,* commentary (1951); W. L. Newman, *Politics,* text and commentary (1887–1902); E. Barker, *Politics*, trans. with introduction and notes (1946); J. E. Sandys, *The Constitution of Athens* (1912). For the *Rhetoric* and the *Poetics:* E. M. Cope and J. E. Sandys, *Rhetoric* (1887); I. Bywater, *Poetics* (1909). For the *Physics* and writings on natural history: W. D. Ross, *Physics,* text and commentary (1936), W. K. C. Guthrie, *De caelo,* text and trans. (1939); H. D. P. Lee, *Meteorologica,* text and trans. (1952); A. L. Peck, *De partibus animalium,* text and trans. (1937); W. D. Ross, *Parva naturalia,* text and commentary (1955); H. H. Joachim, *De generatione et corruptione* (1922). For the *Metaphysics:* W. D. Ross, *Metaphysics* (1924). For psychology: W. D. Ross, *De anima* (1956). For fragmentary works: V. Rose, *Fragmenta* (1886); R. Walzer, *Dialogorum fragmenta* (1934); W. D. Ross, *Fragmenta selecta* (1953).

Modern works dealing generally with the thought of Aristotle and with the body of his writings include: W. Jaeger, *Aristoteles* (1923; 2nd ed. as Eng. trans., 1948), W. D. Ross, *Aristotle* (1923; rev. ed., 1949); D. J. Allan, *The Philosophy of Aristotle* (1952).

Among modern works dealing with particular treatises or themes mention may be made of the following. On logic: J. Lukasiewicz, *Aristotle's Syllogistic From the Standpoint of Modern Formal Logic* (1952). On the *Ethics* and the political writings: M. E. Hamburger, *Morals and Law: the Growth of Aristotle's Legal Theory* (1951); A. Mansion, *Autour des Éthiques attribués à Aristote* (1931); R. Walzer, *Magna Moralia und Aristotelische Ethik* (1929); E. Barker, *The Political Thought of Plato and Aristotle* (1906); W. Oncken, *Die Staatslehre des Aristoteles* (1870). On the *Physics* and on the works of natural history: A. Mansion, *Introduction à la physique aristotélicienne* (1913; 2nd ed., 1931); T. E. Jones, *Aristotle's Researches in Natural Science* (1912); W. D'Arcy Thompson, essay in *The Legacy of Greece*, ed. by R. W. Livingstone (1921). On the *Metaphysics* and on general philosophy: H von Arnim, *Die Entstehung der Gotteslehre des Aristoteles* (1929); E. Bignone, *L'Aristotele perduto e la formazione filosofica di Epicuro* (1934); H. Cherniss, *Aristotle's Criticism of Plato and the Academy* (1944-), W Jaeger, *Studien zur Entstehungsgeschichte der Metaphysik des Aristoteles* (1912); J. Stenzel. *Zahl und Gestalt bei Platon und Aristoteles* (1924); J. Wilpert, *Zwei Aristotelische Frühschriften über die Ideenlehre* (1949). On psychology: H. Cassirer *Aristoteles Schrift von der Seele* (1932); F. Nuyens, *L'Évolution de la psychologie d'Aristote* (1939).

On the history of Aristotle's writings in the middle ages the following works may be mentioned: T. J. de Boer, *Geschichte der Philosophie im Islam* (1901); M. Grabmann, *Forschungen uber die lateinischen Aristoteles-Übersetzungen des 13. Jahrhunderts* (1916); E. Renan *Averroès et l'averroisme* (1866); F. von Steenberghen, *Aristotle in the West: the Origin of Later Aristoteleanism* (1955). (E. B.)

ARISTOTLE'S LANTERN, the name applied to the complex masticatory apparatus of sea urchins. *See* SEA URCHIN.

ARISTOXENUS (fl. late in the 4th century B.C.), Greek philosopher, the first authority for musical theory in the classical world, was born at Tarentum (Taranto) in southern Italy but studied under Aristotle and Theophrastus in Athens and became one of the Peripatetics (*q.v.*). He was interested in ethics as well as in music and wrote much, but most of his work is lost. Apart from his musical treatises, fragments of his reconstruction of the old Pythagorean ethics as well as of his biographies of Pythagoras, of Archytas, of Socrates and of Plato are still extant. His theory that the soul is related to the body as harmony to the parts of a musical instrument seems to follow early Pythagorean doctrine.

In musical theory Aristoxenus held that the notes of the scale are to be judged not by mathematical ratio but by the ear. Parts of his *Elements of Harmony* and of his *Elements of Rhythm* are extant.

The *Elements of Harmony* was edited by P. Marquard (1868) and by H. Macran (1902). *Elements of Rhythm* by R. Westphal (1861 and 1883). The fragments of his other works were edited by F. Wehrli in *Aristoxenos*, being part ii of Wehrli's *Die Schule des Aristoteles; Texte und Kommentar* (1945). (F. W1)

ARITHMETIC. The word arithmetic is derived from the Greek word *arithmos*, meaning "number." The term is ordinarily applied to the more elementary aspects of the theory of numbers, in particular to the arts of mensuration and computation.

There is a tendency to consider arithmetic not as a logically defined branch of mathematics but rather as consisting of those topics which are taught before algebra. From this point of view arithmetic is not concerned with negative numbers or with literal notation. A few simple geometric concepts such as area and volume are frequently included.

The term arithmetic usually implies a limitation in rigour as

marked as the limitations in subject matter; for example, the incommensurable numbers are ordinarily assumed with very little attempt at justification. The point of view is generally utilitarian and dogmatic. A student who is interested in the logical foundations of arithmetic should consult a book on the theory of numbers. (See NUMBERS, THEORY OF.)

There have been, on the other hand, a few mathematicians who would consider arithmetic to be synonymous with the theory of numbers or at least with some parts of the theory of numbers. Thus Leonard Eugene Dickson speaks of the arithmetic of a linear associative algebra, meaning the number theory of the maximal integral ring of that algebra.

The Fundamental Laws for the Positive Integers.—Two sets of objects which can be paired so that each pair contains one object from each set are said to possess the same (cardinal) number. If a set of objects can be thus paired with the symbols of the sequence 1, 2, 3, . . . , n, then the set is said to contain the number n of objects. The determination of this number n is called counting. The numbers thus obtained are known as the natural numbers, the whole numbers or the positive integers.

If a set A contains a objects and a set B contains b objects, the two sets together constitute a set containing $a + b$ objects. The number $a + b$ is called the sum of the numbers a and b, the numbers a and b are called the summands, and the binary operation of forming the sum is called addition. The symbol $+$ of this operation is read plus.

From the process of counting it is evident that the following fundamental laws hold for the operation of addition:

1. The commutative law of addition: $a + b = b + a$
2. The associative law of addition: $a + (b + c) = (a + b) + c$

If there exists a positive integer k such that $a = b + k$, it is said that a is greater than b (written $a > b$), and that b is less than a (written $b < a$). If a and b are any two positive integers, either $a = b$ or $a > b$ or $a < b$.

From the above laws it is evident that a repeated sum such as $5 + 5 + 5$ is independent of the way in which the summands are grouped and is written 3×5. Thus a second binary operation called multiplication is defined. The number 5 is called the multiplicand, the number 3 which denotes the number of summands is called the multiplier and the result 3×5 is called the product. The symbol $\times$ of this operation is read times. If letters such as a and b are used to denote the numbers, the product $a \times b$ is often written $a.b$ or simply ab.

If 3 rows of 5 dots each are written,

```
. . . . .
. . . . .
. . . . .
```

it is clear that the total number of dots in the array is 3×5 or 15. This same number of dots can evidently be written in 5 rows of 3 dots each, whence $5 \times 3 = 15$. The argument is general, leading to

3. The commutative law of multiplication: $ab = ba$

By the use of a three-dimensional array of dots, the following law becomes evident:

4. The associative law of multiplication: $a(bc) = (ab)c$

Separate the 15 dots written above into two sets:

```
. . .   . .
. . .   . .
. . .   . .
```

The first set consists of 3 columns of 3 dots each, or 3×3 dots; the second set consists of 2 columns of 3 dots each, or 2×3 dots; the sum $3 \times 3 + 2 \times 3$ consists of $3 + 2 = 5$ columns of 3 dots each, or $(3 + 2) \times 3$ dots. In general one may prove

5. The distributive law: $(a + b)c = ac + bc$

Just as a repeated sum $a + a + \ldots + a$ of k summands is written ka, so a repeated product $a \times a \times \ldots \times a$ of k factors is written a^k. The number k is called the exponent and a the base of the power a^k.

The following fundamental laws of exponents follow easily from the definitions:

6. $a^m a^n = a^{m+n}$ 7. $(a^m)^n = a^{mn}$ 8. $a^m b^m = (ab)^m$

Other laws such as

$$a^m \div a^n = a^{m-n} \qquad m > n$$

are immediate consequences of these.

Theory of Divisors.—If three positive integers a, b and c are in the relation $ab = c$, it is said that a and b are divisors or factors of c, or that a divides c (written $a \mid c$) and b divides c. The number c is said to be a multiple of a and a multiple of b.

The number 1 is called the unit, and it is clear that 1 is a divisor of every positive integer. If c can be expressed as a product ab where a and b are positive integers each greater than 1, then c is called composite. A positive integer neither 1 nor composite is called prime. Thus 2, 3, 5, 7, 11, 13, 17, 19, . . . are prime numbers. Euclid proved that the number of prime numbers is infinite (*Elements*, book ix, proposition 20).

The fundamental theorem of arithmetic (Carl Friedrich Gauss, *Disquisitiones Arithmeticae*, 1801) states that every composite number can be expressed as a product of prime numbers and that, save for the order in which the factors are written, this representation is unique. This theorem follows rather directly from a theorem of Euclid (*Elements*, book vii, prop. 30) to the effect that if a prime divides a product, it divides one of its factors, and the fundamental theorem is therefore sometimes credited to Euclid.

For every finite set $a_1, a_2, \ldots, a_k$ of positive integers, there exists a largest integer d which divides each of these numbers, called their greatest common divisor (g.c.d.). If $d = 1$, the numbers are said to be relatively prime. There also exists a smallest positive integer m which is a multiple of each of the numbers. This is called their least common multiple (l.c.m.).

If $p_1, p_2, \ldots, p_h$ are the distinct primes which divide all of the numbers $a_1, a_2, \ldots, a_k$, and if e_i is the smallest exponent to which p_i occurs in any of them, then

$$d = p_1^{e_1} p_2^{e_2} \ldots p_h^{e_h}$$

is the g.c.d. of $a_1, a_2, \ldots, a_k$. If $p_1, p_2, \ldots, p_t$ are the distinct primes which divide any one or more of the numbers $a_1, a_2, \ldots, a_k$, and if n_i is the largest exponent to which p_i occurs in any of them, then

$$m = p_1^{n_1} p_2^{n_2} \ldots p_t^{n_t}$$

is the l.c.m. of $a_1, a_2, \ldots, a_k$. Thus if

$$a_1 = 2^3.3.5^3.7^4 \qquad a_2 = 2.3^5.7^3.11^3$$
$$d = 2.3.7^3 \qquad m = 2^3.3^5.5^3.7^4.11^3$$

Obviously if $k = 2$, $a_1 a_2 = dm$.

If a and b are two positive integers, $a > b$, by means of the division algorithm (*q.v.*) two integers q and r can be determined such that

$$a = bq + r \qquad 0 \leqq r < b$$

The number q is called the partial quotient (the quotient if $r = 0$) and r is called the remainder. The g.c.d. of a and b is equal to the g.c.d. of b and r. If the division algorithm is applied successively, a remainder 0 must ultimately appear. The last remainder > 0 is the g.c.d. of a and b. Thus if $a = 544$, $b = 119$,

$$544 = 4.119 + 68 \qquad 119 = 1.68 + 51$$
$$68 = 1.51 + 17 \qquad 51 = 3.17$$

The g.c.d. of 544 and 119 is 17.

This process is known as the Euclid algorithm (*Elements*, book vii, prop. 1). By means of it, the g.c.d. can be obtained without first factoring the numbers a and b into prime factors.

Common Fractions.—In certain problems it may happen that the unit of measure is inconveniently large. Thus in measuring the width of a room the number of feet in this width may not give a sufficiently accurate measurement. In such a case a smaller unit of measure called the inch may be adopted, 12 of which are equivalent to one foot. But without surrendering the foot as the fundamental unit, the inch may be denoted by the symbol $\frac{1}{12}$. (See FRACTION.)

In general the fractional unit $\frac{1}{d}$ is defined by the property $d \times \frac{1}{d} = 1$. The number $a \times \frac{1}{d}$ is written $\frac{a}{d}$ and is called a (common or vulgar) fraction. It may be considered as the quotient of a divided by d. The number d is called the denominator (since it determines the fractional unit or denomination) and a is called the numerator (since it enumerates the number of fractional units which are taken). The numerator and denominator together are called the terms of the fraction.

A positive fraction $\frac{a}{d}$ is said to be proper if $a < d$, otherwise improper.

The positive integers and fractions are sometimes called the positive rational numbers.

The numerator and denominator of a fraction are not unique, since for every positive integer k,

$$\frac{a}{d} = \frac{ka}{kd}$$

Clearly every fraction can be written as the quotient of two relatively prime integers. In this form it is said to be in lowest terms.

It is not difficult to show that the five fundamental laws, which in the first section were proved to hold for positive integers, hold more generally for all positive rational numbers.

It is obvious from the definition of fraction that the sum (or difference) of two fractions having the same denominator is a fraction with this denominator whose numerator is the sum (or difference) of the numerators of the given fractions. Two fractions having different denominators may be added by first reducing them to fractions with the same denominator. Thus to add $\frac{a}{d}$ and $\frac{b}{e}$ we first determine the l.c.m. m of d and e, often called the least common denominator of the fractions. Then there exist numbers k and l such that $m = kd = le$,

$$\frac{a}{d} = \frac{ka}{kd} = \frac{ka}{m}, \quad \frac{b}{e} = \frac{lb}{le} = \frac{lb}{m}$$

so that

$$\frac{a}{d} \pm \frac{b}{e} = \frac{ka}{m} \pm \frac{lb}{m} = \frac{ka \pm lb}{m}$$

The product of two fractions is a fraction whose numerator is the product of the numerators of the factors, and whose denominator is the product of the denominators of the factors. Thus

$$\frac{a}{d} \times \frac{b}{e} = \frac{ab}{de}$$

The quotient of two fractions is equal to the product of the dividend by the divisor inverted, *i.e.*, the divisor with its terms interchanged. That is,

$$\frac{a}{d} \div \frac{b}{e} = \frac{a}{d} \times \frac{e}{b} = \frac{ae}{db}$$

A method of introducing the positive rational numbers which is free from intuition was given by Ernst Steinitz in 1910. Consider the set of all number pairs (a,d), (b,e), . . . where a, b, d, e, . . . are positive integers. Define the equals relation $(a,d) = (b,e)$ to mean that $ae = bd$. Define the two operations $+$ and $\times$ as follows:

$$(a,d) + (b,e) = (ae + bd,\ de)$$
$$(a,d) \times (b,e) = (ab,\ de)$$

It can now be proved that the fundamental laws of section one hold for these pairs, and that the pairs of the type $(a,1)$ are abstractly identical with the positive integers a. Moreover, $d \times (a,d) = a$, so that the pair (a,d) is abstractly identical with the fraction $\frac{a}{d}$.

Irrational Numbers.—It was known to the Pythagoreans that, given a straight line segment a and a unit segment u, it is not always possible to find a fractional unit such that both a and u are multiples of it. Thus the hypotenuse of an isosceles right triangle whose sides are taken as the unit u must by the Pythagorean theorem have a length whose square is 2, *i.e.*, a length of $\sqrt{2u}$. But there exists no rational fraction whose square is 2.

It is customary to assume as an axiom that, corresponding to every line segment and every unit length, there exists a number (called a positive real number) which represents the length of the line segment. Not all such numbers are rational, but every one can be approximated arbitrarily closely by a rational number. That is, if α is real and ϵ is any positive rational number no matter how small, it is possible to find two positive rational numbers a and b such that

$$a < \alpha < b \qquad a - b < \epsilon$$

In problems in mensuration, real numbers are usually replaced by rational approximations.

A rigorous development of the irrational numbers is beyond the scope of arithmetic. They are most satisfactorily introduced by means of Dedekind cuts or Cauchy (or regular or fundamental) sequences or the infinite decimals of Georg Cantor. These methods are discussed in books on the theory of functions of a real variable.

The employment of irrational numbers greatly increases the scope and usefulness of arithmetic. For instance, if n is any whole number and a is any positive real number, there exists a unique positive real number $\sqrt[n]{a}$, called the nth root of a, whose nth power is a. The root symbol $\surd$ is a conventionalized r for radix or root.

The term evolution is sometimes applied to the process of finding a rational approximation to an nth root.

A number such as

$$\sqrt[3]{\frac{\sqrt{2} + \sqrt[6]{3}}{\sqrt{5}}}$$

which is obtainable from rational numbers by a finite number of additions, multiplications, divisions and root extractions is called a surd. An irrational number of the form $\sqrt{a}$ where a is rational is called a pure surd of index n. For $n = 2$, it is called a quadratic surd or square root and is written simply $\sqrt{a}$. A surd which is not pure is called mixed.

A pure surd of index n may be reduced to a rational multiple of the nth root of a positive integer no prime factor of which occurs to an exponent as high as n. Such a surd is in lowest terms. Thus consider $\sqrt[3]{125/18}$. Since $18 = 2.3^2$, it becomes a perfect cube upon multiplication by $2^2.3 = 12$. Then

$$\sqrt[8]{\frac{125}{18}} = \sqrt[3]{\frac{125 \cdot 12}{18 \cdot 12}} = \sqrt[3]{\frac{5^3 \cdot 12}{6^3}} = \frac{5}{6}\sqrt[3]{12}$$

Two surds which can be written as rational multiples of the same surd are called similar. Their sum is similar to each of them, its rational coefficient being the sum of the rational coefficients of the summands.

The following elementary properties of surds are readily provable:

9. $\sqrt[n]{a} \cdot \sqrt[n]{b} = \sqrt[n]{ab}$

10. $\sqrt[n]{\sqrt[m]{a}} = \sqrt[mn]{a}$

11. $(\sqrt[m]{a})^k = \sqrt[m]{a^k}$

12. $\sqrt[mn]{a^{kn}} = \sqrt[m]{a^k}$

13. $\sqrt[n]{\frac{a}{b}} = \frac{\sqrt[n]{a}}{\sqrt[n]{b}}$

The theory of surds can be much simplified by the introduction of negative and fractional exponents. By definition

$$a^0 = 1 \qquad a^{-n} = 1/a^n \qquad a^{p/q} = \sqrt[q]{a^p} \qquad a \neq 0$$

It can be shown that the fundamental laws of exponents (6), (7) and (8) together with the properties of the rational fractions, are equivalent to the above elementary properties (9), (10), (11) and (12). For instance,

$$\sqrt[n]{a} \cdot \sqrt[n]{b} = a^{1/n}b^{1/n} = (ab)^{1/n} = \sqrt[n]{ab}$$

$$\sqrt[m]{a^k} = a^{k/m} = a^{kn/mn} = \sqrt[mn]{a^{kn}}$$

The Decimal System.—It was only after the adoption of the Hindu-Arabic, or decimal, notation that the easy methods in use for adding, subtracting, multiplying and dividing were possible. In this notation every number is written as a linear combination of powers of 10.

Thus

$$32{,}158 = 3.10^4 + 2.10^3 + 1.10^2 + 5.10 + 8$$

where each coefficient is $\geqq 0$ and $\leqq 9$.

Large numbers are usually separated into periods of three digits each, starting at the right, or at the decimal point in the case of a fraction.

This makes it easier to tell at a glance the approximate size of the number.

The notations

32 158   32,158   32'158

are all in use.

The use of 10 as a base is doubtless due to the fact that early man used his 10 digits or fingers as counters. There are vestiges of systems using the base 12 (the dozen and gross), the base 20 (the score) and the Babylonian system with base 60 which still survives in our system of dividing the angular degree into minutes.

From time to time there has been some agitation to supplant the decimal system with the duodecimal system having 12 as its base, but the advantages of this system over the decimal system are scarcely material.

With the introduction of decimal fractions, the decimal system has been extended so that all positive numbers, integral, fractional and irrational, can be approximated to any desired degree of accuracy by a decimal number.

Thus

$$241\frac{37}{100} = 2.10^2 + 4.10 + 1.10^0 + 3.10^{-1} + 7.10^{-2} = 241.37$$

The decimal point precedes the digits which are coefficients of negative powers of 10. This is written as a period in the United States but is slightly raised (241·37) in Britain, while the French use a comma (241,37). (*See* NUMBER; NUMERALS AND NUMERAL SYSTEMS: FRACTION.)

Addition and Subtraction.—Numbers in decimal notation can easily be added by adding the coefficients of corresponding powers of 10, and then adjusting the coefficients which exceed 9 by the process known as carrying.

For example:

$$\begin{array}{lrrrrrr}
47.65 = & & 4.10 + & 7 + & 6.10^{-1} + & 5.10^{-2} & \\
5.473 = & & & 5 + & 4.10^{-1} + & 7.10^{-2} + & 3.10^{-3} \\
\underline{649.8} = & \underline{6.10^2 +} & \underline{4.10 +} & \underline{9 +} & \underline{8.10^{-1}} & & \\
\text{Sum} = & 6.10^2 + & 8.10 + & 21 + & 18.10^{-1} + & 12.10^{-2} + & 3.10^{-3}
\end{array}$$

After adjustment of the coefficients, this is

$$7.10^2 + 0.10 + 2 + 9.10^{-1} + 2.10^{-2} + 3.10^{-3} = 702.923$$

The process of addition is commonly carried out as follows.

$$\begin{array}{r} \underline{2\,1\,1} \\ 47.65 \\ 5.473 \\ \underline{649.8} \\ 702.923 \end{array}$$

Begin at the right. The sum of the coefficients of 10^{-3} is 3, which is written below the answer line. The sum of the coefficients of 10^{-2} is 12; the digit 2 is placed to the left of the 3 in the sum, but the 10 becomes a 1 in the preceding position and may be placed at the top of the column of coefficients of 10^{-1}, etc. In practice the "carrying" is usually performed mentally.

Subtraction is performed by reversing the above procedure. In order to subtract 170.8 from 563.142, place the smaller number

$$\begin{array}{r} 563.142 \\ \underline{170.8} \\ 392.342 \end{array}$$

under the larger with the decimal points under each other. Begin at the right. Since .8 = .800, 0 subtracted from 2 is 2 (which is written below the line) and 0 from 4 is 4. Since 8 exceeds 1, a unit is borrowed from unit's place (which changes the 3 to 2) and the 1 in tenth's place becomes 11. Then 8 from 11 is 3, 0 from 2 is 2, etc.

Multiplication.—Multiplication of decimal numbers is based upon the distributive law. Thus

$$\begin{aligned} 25.78 \times 7 &= 20 \times 7 + 5 \times 7 + .7 \times 7 + .08 \times 7 \\ &= 140 + 35 + 4.9 + .56 = 180.46 \end{aligned}$$

This process may be carried out as follows by a process known

$$\begin{array}{r} \underline{45\;5} \\ 25.78 \\ \underline{7} \\ 180.46 \end{array}$$

as short multiplication. Start at the right. Since $7 \times 8 = 56$, write 6 below the answer line, and place the 5 above the 7 in the multiplicand. Then $7 \times 7 = 49$, to which is added the 5 which was carried, making 54. The 4 is written in the answer, the 5 is carried as before. The numbers written above the top line are usually carried mentally.

If the multiplier has more than one digit, long multiplication is used. This process also is based upon the distributive law. The

$$\begin{array}{r} 25.78 \\ \underline{45.7} \\ 18046 \\ 12890 \\ \underline{10312} \\ 1178.146 \end{array}$$

first partial product is 18.046, which was obtained by multiplying 25.78 by .7 by short multiplication. The second partial product is $25.78 \times 5 = 128.90$; the third is $25.78 \times 40 = 1031.2$. The product is the sum of these partial products. It is customary to ignore the decimal point in these partial products but to indent each partial product one more place than the partial product above it. In the product, point off from the right as many digits as the sum of the number of digits to the right of the decimal point in the multiplicand and the number of digits to the right of the decimal point in the multiplier.

When only approximate accuracy is demanded, a shorter form of multiplication may be used. If measurements can be made

$$\begin{array}{r} 2.578 \\ \underline{.457} \\ 18 \\ 129 \\ \underline{1031} \\ 1.178 \end{array}$$

only to three decimal places, the accuracy of the product beyond three places is fictitious. The number 2.578 is rounded off to 2.6; then $6 \times 7 = 42$, which is rounded to 40, and the 4 is carried. Then $2 \times 7 + 4 = 18$, which is the first partial product. Next 2.578 is rounded off to 2.58, $8 \times 5 = 40$, again giving 4 to be carried; $25 \times 5 + 4 = 129$, which is the second partial product. In the last step 2.578 is not rounded off, $8 \times 4 = 32$, which gives 3 to carry and $257 \times 4 + 3 = 1.031$. The approximate product is the sum, 1.178. As many decimal places are pointed off from the right as there are in each of the given numbers, namely three.

Another short method which is useful in the hands of experts is as follows. Start at the right. Since $8 \times 7 = 56$, write 6 in the

$$\begin{array}{r} 25.78 \\ \underline{45.7} \\ 1178.146 \end{array}$$

answer and carry 5. Then $7 \times 7 + 8 \times 5 + 5 = 94$; write 4 and carry 9. Then $5 \times 7 + 7 \times 5 + 8 \times 4 + 9 = 111$; write 1 and carry 11. Then $2 \times 7 + 5 \times 5 + 7 \times 4 + 11 = 78$; write 8 and carry 7. Then $2 \times 5 + 5 \times 4 + 7 = 37$; write 7 and carry 3. Finally, $2 \times 4 + 3 = 11$, which is written down. The product is 1,178.146.

Division.—The division algorithm was mentioned earlier. If a and b are two whole numbers, $a > b$, there exist two whole numbers q and r such that

$$a = bq + r \qquad 0 \leqq r < b$$

The process of finding these numbers can be carried out by the processes called long and short division.

If $b < 10$, say $b = 7$, use short division. Let $a = 53{,}149$. Start at the left. Since $5 < 7$, consider the first two digits, 53. The

$$\begin{array}{r} 4\;6\,1\,5 \\ 7\,\overline{)\,53\;1\,4\,9} \\ 7\;5\,9\,2 \end{array}$$

largest multiple of 7 which is less than or equal to 53 is $49 = 7 \times 7$. Write 7 below the 3, and the remainder, $53 - 49 = 4$, above the 3. This remainder with the next digit in the dividend is 41; the largest multiple of $7 \leqq 41$ is $35 = 7 \times 5$. Write 5 below the 1 and the remainder $41 - 35 = 6$ above the 1. The last remainder is 5. Usually the remainders which have been written above the dividend are carried mentally and not written down.

It should be noted that this process involves guessing the largest multiple of the divisor which is less than a certain number. But only a few guesses are ever required and no practical difficulty is encountered.

Since $53{,}149 = 7{,}592 \times 7 + 5$, one may write

$$\frac{53{,}149}{7} = 7{,}592\tfrac{5}{7}$$

where 7,592 is the partial quotient and 5 is the remainder.

If the divisor exceeds 10, long division is preferable. Let it be required to divide 83,742 by 621. Since the largest multiple of $621 \leqq 837$ is 621×1, write 1 as the first digit of the quotient and subtract 621×1 from 837. Actually what is done is to subtract 621×100 from 83,742 leaving a remainder of 21,642. Since only the 2,164 will be used in the next step, the final 2 of the dividend need not be brought down yet. The largest multiple of $621 \leqq 2{,}164$ is $621 \times 3 = 1{,}863$, and the remainder is 301.

```
621) 83742 (134
     621
     2164
     1863
      3012
      2484
       528
```

Now the final 2 must be brought down to make 3,012. The largest multiple of $621 < 3{,}012$ is $621 \times 4 = 2{,}484$, and the remainder is 528.

Thus

$$83{,}742 = 621 \times 134 + 528$$

This method of long division can be condensed as follows by subtracting the partial product as it is formed:

```
621) 83 742  (134
     21 64
      3 012
        528
```

By this process it is possible to express an improper fraction as the sum of an integer and a proper fraction,

$$\frac{83\,742}{621} = 134\frac{528}{621}$$

If it is preferable to express the result as a decimal fraction carried out to any desired number of decimal places, the process is merely continued:

```
621) 83742 (134.8502
      2164
       3012
        5280
         3120
           1500
            258
```

$$\frac{83742}{621} = 134.8502$$

Any two numbers written decimally may be so divided. The number of digits to the right of the decimal point in the quotient is equal to the number of such digits in the dividend diminished by the number of such digits in the divisor, care being necessary to add to the dividend all 0s which are brought down. Thus in the above example

$$\frac{83742.0000}{621} = 134.8502$$

An alternative method for determining the position of the decimal point in the quotient is to write

$$\frac{83742}{621} = \frac{837.42}{6.21} = 134.8502$$

making the divisor lie between 0 and 10, whence it is obvious that the quotient lies between 100 and 1,000.

Square and Cube Root.—An algorithm for the determination of the square root of a decimal number is carried out as follows.

```
      15 78.42 (39.72
       9
  69 | 678
     | 621
 787 | 5742
     | 5509
7942 | 23300
     | 15884
        7416
```

Starting at the decimal point, the number is separated into periods of two digits each. The leftmost period is 15, and the largest square $\leqq 15$ is $9 = 3^2$. The 3 is written at the right and the remainder $15 - 9 = 6$ is brought down. The next period 78 is brought down beside the 6, giving 678. The 3 is doubled and written at the left. By trial it is found that 9 is the largest digit such that $69 \times 9 = 621 \leqq 678$. The 9 is written after the 3 in the answer, and the difference 57 is brought down, followed by the next period 42. The partial answer 39 is doubled and written at the left under the 69. By trial it is found that $787 \times 7 = 5{,}509 \leqq 5{,}742$ while $788 \times 8 > 5{,}742$. The next digit in the answer is therefore 7. The process is continued until the desired degree of accuracy is attained. In the present example the last remainder 7,416 exceeds half of the last trial divisor 7,942 so that 3 is a better approximation than 2 for the last digit. In fact $39.73^2 = 1{,}578.4729$.

The above process is based upon the relation $(a + b)^2 = a^2 + (2a + b)b$. In each step the part of the square root already obtained is a; the part remaining to be found is b. In the example, $(a + b)^2 = 1{,}578.42$, $a = 30$. Then $2ab + b^2 = 678.42$. In order to determine the largest integer n in b, one must find the largest integer n (namely 9) such that $(2a + n)n \leqq 678.42$. The trial divisor is $2a + n = 69$. In the next step $a = 39$, $2ab + b^2 = 57.42$ etc.

Cube and Higher Roots.—The cube root of a number may be calculated by a similar algorithm based upon the relation

$$(a + b)^3 - a^3 = (3a^2 + 3ab + b^2)b$$

Thus to find the approximate cube root of 279,463, proceed as in the example.

```
          279 463.000 (65.38−
          216
    10800 | 63 463
      900 |
       25 |
    11725 | 58 625
  1267500 | 4 838 000
     5850 |
        9 |
  1273359 | 3 820 077
127922700 | 1 017 923 000
   156720 |
       64 |
128079484 | 1 024 635 872
```

This last remainder is too large, but much closer than the remainder resulting from using 7 as the last digit.

A fourth root is easily obtained as the square root of the square root. Fifth and higher roots can be obtained by an algorithm similar to those just given, based upon the expansion of $(a + b)^n$ by the binomial theorem. The method is cumbersome and is seldom used, for the method of logarithms is easy and rapid.

In fact, if tables of logarithms are not available, the fifth root of a (for instance) can be quite quickly found by solving the equation $x^5 - a = 0$ by Newton's or Horner's method. (*See* EQUATIONS, THEORY OF.)

Checking.—An easy and fairly reliable check applicable to any arithmetic calculation is based upon the method of "casting out nines." This method, presumably of Hindu origin, has been known for a thousand years. The proof of its validity may be found in any book on the theory of numbers.

Let a and m be any positive integers. By the division algorithm there is a unique least positive remainder a' such that

$$a = qm + a' \qquad 0 \leqq a' < m$$

Similarly let b determine the least positive remainder b', and let c similarly determine c'. If $a + b = c$, then $a' + b'$ has the same least positive remainder c' as does c; if $ab = c$, then $a'b'$ likewise determines c'; and if $a^n = c$, then a'^n determines c'.

If $m = 9$ is chosen, the check is particularly simple to apply for then 10, 100, 1,000, . . . each have the least positive remainder 1 so that every number determines the same least positive remainder as does the sum of its digits.

Consider the multiplication problem of the section on multiplication, $25.78 \times 45.7 = 1{,}178.146$. Let $a = 2{,}578$, $b = 457$, $c =$ 1,178,146. Then $a' = 4$, $b' = 7$, $c' = 1$. To find c', for instance, add the digits of c, getting 28; the sum of the digits of 28 is 10; the sum of the digits of 10 is 1, so that $c' = 1$. Now $a' \times b' = 28$ also determines 1, which checks the multiplication. It does not, of course, check the placing of the decimal point.

Consider the square root problem of the section on square root. We found that the approximate square root of 1,578.42 was 39.72 with a remainder of 7,416. Let $a = 157{,}842$, $b = 3{,}972$, $r =$ 7,416. Then $a' = 0$, $b' = 3$, $r' = 0$. To check, $b'^2 + r'$ must have the same least positive remainder as a, namely 0, which it does.

It should be remembered that this check is not infallible. The problem may be incorrect and still check, but this situation will occur only if the error is divisible by 9. But if the problem does not check, either the problem or the check necessarily contains a numerical error.

Logarithms.—If $10^x = n$, then x is called the (common) logarithm of n, written $x = \log n$. Except for a very few numbers n the logarithm of n is irrational and is usually represented by its decimal approximation. Since logarithms are fully treated elsewhere (*see* LOGARITHMS) their applications to arithmetic will be only briefly sketched.

Since $\log xy = \log x + \log y$, the product of two numbers is quickly obtainable by logarithms. Using four-place tables, it is

found that

$$\begin{aligned} \log\ 2.578 &= .4113 \\ \log\ .457 &= 9.6599 - 10 \\ \hline &.0712 = \log\ 1.178 \end{aligned}$$

Hence the product $2.578 \times .457$ is equal to 1.178 to four significant figures.

Similarly division may be performed by subtracting logarithms. If accuracy to five significant figures is desired, five-place logarithms must be used. Thus

$$\begin{aligned} \log\ 837.42 &= 2.92294 \\ \log\ 6.21 &= .79309 \\ \hline &2.12985 = \log\ 134.85 \end{aligned}$$

so that $837.42 \div 6.21 = 134.85$.

Perhaps the most spectacular common use of logarithms is in finding powers and roots. This application is based upon the relation

$$\log x^k = k \log x$$

For $k = 1/3$, $\log \sqrt[3]{x} = \frac{1}{3} \log x$. Using six-place tables,

$$\begin{aligned} \log\ 279{,}463 &= 5.446324 \\ 1/3\ \log\ 279{,}463 &= 1.815441 = \log\ 65.3795 \end{aligned}$$

Thus $\sqrt[3]{279{,}463} = 65.3795$ to six significant figures.

ARIUS (d. *c.* A.D. 335), Christian priest at Alexandria who was the originator of Arianism (*q.v.*), the theory that Christ, the Son of God, is not divine but a created being. Born in Libya, and possibly a pupil of Lucian of Antioch, Arius was made a deacon at Alexandria under the bishop Peter (300–311), but was excommunicated for his association with the Meletians (*see* MELETIUS), being restored under Achillas (311–312) and advanced to the priesthood in charge of the church of Baucalis.

Arius came into conflict with Bishop Alexander (312–328), according to some scholars in 318, according to others in 323. The sequence of events is uncertain, but if 323 is accepted, a reasonable chronology can be presented. In Aug. 323 Alexander investigated Arius' teaching. Arius then wrote to Eusebius of Caesarea (*q.v.*) seeking his support and also to Eusebius of Nicomedia (*q.v.*), a statesman-bishop who had the ear of Constantia, sister of the emperor Constantine I and wife of Licinius. In September a synod of Alexandrian clergy condemned his teaching. Meanwhile another synod in Palestine obtained an undertaking from the Arians that they would refrain from public disputation, together with a doctrinal statement upon which a truce could be negotiated. Alexander accepted this. In October another synod met in Bithynia under Eusebius of Nicomedia and declared that the dissidents should be admitted to communion. Alexander replied in March 324 with a provincial synod, which did not repudiate the truce but anathematized the Arians as a "hands off" sign to overseas bishops.

Arius published his *Thalia* (extant only in so far as it is quoted by Athanasius), partly in verse, to further his views, and in September himself repudiated the truce. In November the emperor decided to intervene, sending Ossius of Cordova, who satisfied himself of the rightness of Alexander's position. In Feb. 325 Arius was condemned by a synod at Antioch, and in March he followed Alexander to Nicomedia. The emperor then summoned an ecumenical council, which met on May 20 at Nicaea and condemned Arius and his teaching (*see* COUNCIL). Arius forthwith was banished to Illyricum, and although he continued to teach there, converting to his ideas such men as Valens of Mursa and Ursacius of Singidunum, he no longer had a principal part to play in the controversy he had originated.

It was not until 332 or 333, after much intrigue, that Constantine wrote to Arius expressing a wish to see him. Arius was mistrustful, but in 335, on receipt of a second letter, he went to Nicomedia and presented a confession of faith which the emperor considered sufficiently orthodox to warrant the reopening of his case. At the synod of Jerusalem, which followed the dedication of the Church of the Resurrection, Arius was declared restored to communion but is said to have died in Constantinople on the eve of the day when he was to be readmitted.

ARIZONA, the "Grand Canyon state," is situated in the southwestern part of the United States between approximately 31° 20′ and 37° N and 109° 2′ and 114° 45′ W. It is bounded north by Utah, east by New Mexico, south by Mexico, and west by California and Nevada, the Colorado River separating it from California and in part from Nevada. Of its total area of 113,909 sq.mi. (water surface, 334 sq.mi.), approximately 39,000 are less than 3,000 ft. above sea level, 27,000 are from 3,000 to 5,000 ft., and 47,000 are above 5,000 ft. The popular name "Apache state" was also given it as the home of the Apache Indians. Arizona is the 6th state of the Union in size. The state capital is Phoenix.

Arizona entered the Union in 1912, as the 48th state. The state flower is the flower of the saguaro cactus; the state tree, the paloverde; and the state bird, the cactus wren. The name Arizona comes from the Indian *arizonac* meaning "little spring."

PHYSICAL GEOGRAPHY

General Features.—Three characteristic physiographic regions are distinctly marked: first, the great Colorado plateau, about 45,000 sq.mi. in area, in the northern part of the state; next, a broad zone of compacted mountain ranges with a southern limit of similar trend; and, lastly, a region of desert plains, occupying the southwestern quarter of the state. The plateau is not a plain. It is dominated by high mountains, gashed by superb river canyons, scarred with dry gullies and washes, the beds of intermittent streams, varied with great shallow basins, sunken deserts, dreary levels, bold buttes, picturesque mesas, forests, and rare verdant bits of valley. The surface in general is rolling, and drains through the Little Colorado (or Colorado Chiquito), Rio Puerco, and other streams into the Grand Canyon (*q.v.*). Along the Colorado is the Painted Desert (*q.v.*), remarkable for the bright colours—red, brown, blue, purple, yellow, and white—of its sandstones, shales, and clays. Within the desert is a petrified forest of Mesozoic time, the most remarkable in the U.S. The marks of volcanic action, particularly lava flows, are abundant and widely scattered.

Separating the plateau from the mountain region is an abrupt transition slope, often deeply eroded, crossing the entire state in a northwest-southeast direction. In localities the slope is a true escarpment falling 150 and even 250 ft. per mile. The mountain region has a width of 70 to 150 mi. and is filled with short ranges parallel to the plateau escarpment. Many of the mountains are extinct volcanoes. The southeastern corner of Arizona is a region of greatly eroded ranges and gently sloping valleys. This mountain zone has an average elevation of not less than 4,000 ft., while in places its crests are 5,000 ft. above the plains. These plains, the third or desert region of the state, have their mountains also, but they are lower and not compacted. The plains near the mountain region slope toward the Gulf of California across wide valleys separated by isolated ranges, then across broad desert stretches traversed by rocky ridges, and finally there is no obstruction to the slope at all.

Climate.—Arizona's climate is marked by extreme variety, re-

MARKOW

STATE CAPITOL AT PHOENIX. THE BUILDING AT CENTRE DATES FROM 1900; THE TWO WINGS, OCCUPIED BY THE SENATE AND THE HOUSE OF REPRESENTATIVES, WERE COMPLETED IN 1960

sulting from the wide range of elevations (from 12,670 ft. at the top of Humphrey's Peak in the San Francisco Mountains to 138 ft. at Yuma) and the approximately 400-mi. difference in latitude from the northern to the southern boundaries of the state. The general classification, however, is arid or semiarid.

Maximum annual precipitation is represented by Crown King's 32.42 in., while the true desert regions are represented by Yuma's 3.10 in. Temperatures in the desert often are higher than those at the Equator, while minimums in Arizona's mountains not infrequently are the lowest recorded in the United States on a given day. Phoenix, typical of the less extreme desert regions, is 1,117 ft. above sea level, and has an annual average temperature of 69° F. Its annual 7.20 in. of precipitation comes principally in July, August, and September, and December, January, and February. Annual relative humidity is fairly constant through the year at 38%, while Phoenix enjoys an annual average of 86% of possible hours of sunshine. Flagstaff, at an altitude of 6,907 ft., is typical of northern Arizona with an annual mean temperature of 45.7° F. Annual precipitation at Flagstaff is 18.31 in. Flagstaff averages 79% of possible hours of sunshine, and its annual average of snowfall totals 74.3 in.

Rainfall comes from the Gulf of Mexico in summer and from the Pacific Ocean or the Gulf of California in winter. Heavy thunderstorms and accompanying cloudbursts are not uncommon in season, and frequently convert the arroyos (dry stream beds) throughout the state into swirling, muddy torrents, occasionally causing flood damage. Sudden spring thaws of mountain snows sometimes flood such streams as the Little Colorado River, the Bill Williams, Oak Creek, the Rio Puerco, and the Hassayampa.

Arizona's diurnal temperature variation is typical of arid and semiarid regions where radiation is rapid. Frequently it is as much as 50° to 60° F. The dry, clear air is one of Arizona's major attractions as a year-round health and vacation resort.

Soil and Irrigation.—The great bulk of Arizona's acreage is composed of mountainous forest and woodland in the northern plateaus, and of desert and grassland in the south and west. The bottomland and lower valleys are very fertile. Since most of the agricultural land is in the semiarid region, water has been the vital problem. Because of the arid climate, the soil is alkaline and contains from 2% to 10% calcium carbonate.

The early melting of the mountain snow makes reservoirs necessary. Several dams were built in early territorial days and frequently destroyed by floods. The Roosevelt Dam, the key structure of the Salt River project, was completed in 1911. It was the first sound construction and was followed by others on the same river. Hoover (Boulder) Dam was completed in 1936. The Upper Colorado Basin compact was completed in 1948 and approved by Arizona in 1949.

Because of the rapidly lowering groundwater level, the Arizona legislature enacted early in the 1950s laws governing the drilling of wells in an attempt to stabilize the declining underground water table. The number of acres irrigated in the state was estimated at more than 1,000,000 in the second half of the 20th century. Arizona pioneered in the area of organized, state-controlled watershed management programs.

Plant and Animal Life.—From the summit of the San Francisco Mountains to the Painted Desert are found representatives of every life zone except the humid tropical. In the highlands coyotes are common; wildcats and mountain lions are fairly plentiful, but animal life is relatively scant. Jaguars occasionally stray into Arizona from Mexico. Lizards and toads are conspicuous in the more desert areas. Snakes are not numerous. The

THE ROOSEVELT DAM ON THE SALT RIVER; COMPLETED IN 1911

Gila monster, tarantula, and scorpion occur in some localities in the rainy season.

A narrow belt along the lower Colorado River, with a short arm extending into the valley of the Gila, supports desert birds and mammals and other desert life. The largest native predator, the grizzly bear, and the most dangerous predator, the lobo wolf, have been hunted to virtual extinction. The native elk met a similar fate, but Arizona now supports a large population of transplanted Wyoming elk. Other large animals found in Arizona include the prong-horned antelope, several varieties of deer, the black and brown bears, and the javelina (a wild boar).

The general conditions of distribution of plant and animal life are shown even more distinctly by the vegetation. There are firs and spruces on the mountains, pines farther down, and piñon juniper, greasewood, and sagebrush in the north, extending as far south as Flagstaff. In southern and western Arizona the giant saguaro cactus grows in groves, attaining a height of 40 and even 50 ft. In many localities the mesquite is the only important native tree. But it is easy to exaggerate the barrenness of an arid country. There are fine indigenous grasses that spring up over the mesas after the summer rains, furnishing range for livestock; some of these grasses are extraordinarily independent of the rainfall. The cliff-dweller country supports a scant vegetation—a few cottonwoods in the washes, some cedars on the mesas.

Continuous forest areas are few. A fair variety of trees—cottonwood, sycamore, ash willow, walnut, and cherry—grow in thickets in the canyons, and each mountain range is a forest area. The lower timberline is about 7,000 ft. and the upper timberline about 11,500 ft. Of Arizona's total area, about 42% supports typical desert vegetation; about 23% is grassland; about 19% is piñon and juniper forest, 9% other forest, and 7% chaparral. From 1898 almost all of the wooded lands were made reservations, and work was done also to preserve the forest areas in the mountains in the southeast, from which there are few streams of permanent flow to the enclosing arid valleys.

Parks and Monuments.—There are a number of national monuments, and Grand Canyon and Petrified Forest National parks, administered by the National Park Service. Prehistoric cliff dwellings are preserved at Canyon de Chelly, Montezuma Castle, Navajo, and Tonto National monuments; cliff dwellings built between A.D. 900 and 1100 are preserved in Walnut Canyon National Monument. A prehistoric pueblo city may be seen at Casa Grande National Monument, and pueblos of more recent occupation (*c.* A.D. 1200) may be seen at Tuzigoot and Wupatki National monuments. Among the natural wonders protected by the national government are the natural rock pinnacles of Chiricahua National Monument; the extinct volcano, ice caves, and lava flows of Sunset Crater National Monument; the petrified trees, Painted Desert, and Indian ruins of Petrified Forest National Park; more than 80 sq.mi. of giant cacti in Saguaro National Monument; and a 330,870-ac. desert supporting the unique cacti of Organ Pipe Cactus National Monument. Tumacacori National Monument houses the ruins of one of the earliest Spanish missions in the territory; and a 40-ac. tract dedicated to American pioneers in Arizona has been preserved as Pipe Spring National Monument. One of the last states to do so, Arizona established in 1957 a state park board to set aside and administer state park areas.

HISTORY

Prehistory.—The history of the southwest is full of interest to the archaeologist. The dryness has preserved invaluable evidences of early cultures which, in other climates, would have disintegrated rapidly. Seeds, cloth, baskets, and even human mummies have been discovered in most sections of the state, giving proof that several well-advanced ancient cultures flourished. Many of the more notable sites of these cultures are preserved as national monuments and parks.

Earliest prehistoric culture proved to have existed in the southwest was the Sandia, which centred in New Mexico *c.* 25,000 B.C. and which quite possibly spread into Arizona and other present states. From about 25,000 to about 10,000 B.C. the Folsom people were in the area, while Yuman people thrived in Colorado.

AUTHENTICATED NEWS INTERNATIONAL

MONTEZUMA CASTLE NATIONAL MONUMENT, NEAR CAMP VERDE, A FIVE-STORY, 20-ROOM SERIES OF CLIFF DWELLINGS DATING FROM ABOUT A.D. 1100

Both probably came into what is now Arizona. They were followed by the increasingly complex Cochise, Hohokam, and Anasazi cultures which have received remarkably detailed study.

The cooperative aspects of the Hohokam culture are demonstrated in the great public works these people built in the Gila and Salt River valleys. They constructed dwellings and extensive systems of dams and ditches for irrigation purposes. In many cases the courses of their canals, laid out with only the crudest of instruments, are followed exactly by modern irrigation waterways.

The Apaches and the Navahos, both primarily nomadic and predatory, appeared in Arizona probably between A.D. 1000 and 1300. The Hohokam culture, which had absorbed such other peoples as the Sinaguans and the Salados from the north disappeared about 1450, probably as a result of a combination of drought, Apache raids, and possibly sickness. Evidence supports the belief that some of the modern Indian tribes of central Arizona are their direct descendants (*see* also INDIAN, NORTH AMERICAN).

Arizona north of the Gila, except for a very limited and intermittent missionary effort and for scant exploring expeditions, was practically unknown to the white man until well after the beginning of rule by the United States. The Santa Cruz Valley, however, has much older annals of a past that charms by its picturesque contrasts with the present.

Spanish Settlement.—Arizona history begins with the arrival in Sonora in 1536 of Alvar Núñez Cabeza de Vaca, whose stories of Arizona and New Mexico incited the Spaniards to explore the unknown north in hope of finding the wealth of the fabled Seven Cities of Cibola. Marcos de Niza, a Franciscan friar to whom the first reconnaissance was entrusted, was, in 1539, the first Spaniard to enter the limits of Arizona. Members of Francisco Vázquez de Coronado's expedition (1540–42) explored the Moqui country and reached the Grand Canyon, and after this a succession of remarkable and heroic explorations followed through the century. All this has left traces in still-living myths about the early history of the southwest. Early in the 17th century considerable progress had been made in Christianizing the Pimas, Papagoes, and Moquis. Following 1680 came a great Indian revolt in New Mexico and Arizona, and thereafter the Moquis remained independent of Spanish and Christian domination, although visited occasionally by rival Jesuits and Franciscans. During this period Jesuit missions

were founded at San Xavier del Bac and Guevavi, but in 1767 the Jesuits were banned from Spanish dominions and superseded by the Franciscans. The region south of the Gila had already been repeatedly explored. In the second half of the 18th century there were a presidio at Tubac and about six *pueblos de visita,* including the Indian settlement of Tucson.

Persistent traditions have greatly exaggerated the former prosperity of the old southwest. The Spaniards probably provoked some intertribal dealings among the Indians, and encouraged agriculture in several tribes. Their own farms and settlements, confined to the Santa Cruz Valley, were often plundered and abandoned, except in the immediate vicinity of the presidio. From about 1790 to 1822 there was a period of peace with the Apaches and of comparative prosperity for church and state. The fine Indian mission church at San Xavier del Bac, long abandoned and neglected, was rebuilt in 1783–97.

In 1752 the first post of Spanish authority on Arizona soil was established as a presidio at the ancient Indian village of Tubac, just north of the Mexican border, on the Santa Cruz River. The establishment of a presidio at Tucson in 1776 marks its beginning as a Spanish settlement, which it remained until 1821 when Mexican independence was granted. The decay of the military power of the presidios during the Mexican War of Independence, the expulsion of loyal Spaniards—notably friars—and the renewal of Apache wars led to the temporary abandonment of all settlements except Tubac and Tucson. The church practically forsook the field about 1828.

United States Entry.—American traders and explorers including Sylvester and James O. Pattie, Bill Williams, Kit Carson, Ewing Young, Pauline Weaver, and Al Sieber first penetrated Arizona in the first quarter of the 19th century. As a result of the Mexican War, New Mexico, which then included all Arizona north of the Gila, was ceded to the U.S. (1848). California gold discoveries drew particular attention to the country south of the Gila, which was wanted also for a transcontinental railway route. This strip was bought in 1853 by the U.S., which took possession in 1856. (*See* GADSDEN PURCHASE.) This portion also was added to New Mexico. The Mexicans, pressed by the Apaches, had in 1848 abandoned Tubac and Tumacacori, first a *visita* of Guevavi, and after 1784 a mission. The progress of U.S. settlement was interrupted by the Civil War, which caused the withdrawal of the troops and the outbreak of prolonged Indian wars.

Meanwhile, a convention at Tucson in 1856 sent a delegate to Congress and petitioned for independent territorial government. The movements that followed were ignored by Congress because of the general slavery question, and especially the belief of northern members that the control of Arizona was an objective of the proslavery party. In 1862 Arizona was established as a separate territory by the Confederate Congress, but Union forces reoccupied Tucson later that year. Congress organized Arizona territory on Feb. 24, 1863, as the country west of 109° W longitude which remained the state's eastern boundary. In December an itinerant government headed by Gov. John N. Goodwin, sent out from Washington, D.C., entered Arizona and effected a formal organization. The territorial capital was first at Prescott and after 1889 at Phoenix.

There were boundary difficulties with every contiguous state or territory. The early period of U.S. rule was extremely unsettled. The California gold discoveries (1849) and overland travel directed many prospecting adventurers to Arizona. For several years there was considerable sentiment in favour of filibustering in Sonora, Mex. The Indian wars, breeding a habit of dependence on force, and the heterogeneous elements of cattle thieves, Sonora cowboys, mine labourers, and adventurers led to one of the worst periods of U.S. border history.

Admission to the Union.—Agitation for statehood, which began as early as 1872, seemed on the point of success in 1891, when a constitution was drafted, submitted to the people of the state, and ratified. The U.S. Senate objected to this constitution because

BY COURTESY OF TUCSON CHAMBER OF COMMERCE; PHOTOGRAPH, RAY MANLEY

INDIAN MISSION CHURCH AT SAN XAVIER DEL BAC, FOUNDED IN 1700 BY PADRE EUSEBIO KINO; REBUILT, 1783–97

it seemed to repudiate certain contracts and set up a double monetary standard. The Senate continued to reject bills providing for statehood until the state sent up a new constitution in 1910. The constitution raised a question of national importance in the form of a provision for the recall of judges by popular vote. After much argument Pres. William Howard Taft and Congress finally agreed on a resolution granting statehood on condition that the provision for recall be struck out. This was done, and on Feb. 14, 1912, the president signed the proclamation admitting Arizona as a state. After admission the people of the state promptly inserted by amendment the original provision for the recall of judges.

George W. P. Hunt, chairman of the Constitutional Convention and a Democrat, was elected as first governor of Arizona in December 1911. His securing for labour certain contested clauses in the constitution won for him the support of that faction. He was reelected in 1914 and in 1916 was a candidate for the third time, but was declared defeated by Thomas E. Campbell, a Republican. After a bitter struggle the state supreme court decided in December 1917 that Hunt had been elected. In 1918 Campbell was elected the first Republican governor.

The political struggle reflected a tense industrial situation. In 1915 a serious strike occurred at Clifton-Morenci in the copper-mining district, and several other camps were struck in the next two years. In 1917 the Industrial Workers of the World (IWW) gained considerable strength in the state and struck a number of mines. A major strike at Bisbee was climaxed by the Bisbee deportation (July 12, 1917) in which more than 1,250 men suspected of being members of the IWW were loaded on railroad cattle cars and boxcars and escorted to Columbus, N.M. The incident became a *cause célèbre*, and repercussions were felt as late as World War II. Arizona mines were not effectively unionized until the mid-1930s. Meanwhile, the railroad brotherhoods and numerous other unions were growing. After 1945 unionization was accelerated by the arrival of many union members during Arizona's postwar population boom, and by the concurrent tremendous increase of industrialization and building in the state.

Colorado River Controversy.—A major problem confronting the state after 1920 was the disposal of the Colorado River water for irrigation and power. The problem was more critical because of the state's location on the Lower Colorado and its inability to develop hydroelectric plants. Governor Hunt, who was elected to the position of chief executive for seven terms, opposed the Colorado River compact and the construction of Hoover Dam on the grounds that Arizona might lose much-needed water that could by agreement go to Mexico. The Parker Dam was also opposed, since it would send Arizona water to Los Angeles, Calif. Arizona in 1931 brought suit to prevent construction on the grounds that the Colorado was a navigable river, but the U.S. Supreme Court subsequently dismissed the case. In 1948 an appropriation was made to aid the Arizona Interstate Stream Commission to stop California's effort "to use all the water in the river." An agreement of the states of the upper basin was reached in 1949, but disputes over the use of the Colorado River continued into the second half of the 20th century. (See *Soil and Irrigation*, above.)

From its admission to the Union, Arizona voted primarily Democratic, especially in local and state elections. From 1930 until 1950 Democrats won every gubernatorial election in the state. After mid-20th century, Republicans gained, winning the governorship in 1950, 1952, and in 1958, 1960, 1962, and 1966.

GOVERNMENT

Arizona was acquired from Mexico in 1848 and became a separate territory in 1863. From that time until attainment of statehood its organic law consisted of sections of the revised statutes of the U.S. While the territory was Democratic, its administrative officials were Republican; so the territorial governor worked with a legislature of the opposite party. One important control was the Arizona rangers, organized in 1901 to protect the cattle interests against thieves. Licensed public gambling was prohibited by law in 1907, but later became a vital issue until an attempted constitutional amendment legalizing gambling was defeated at the election of 1950. The Constitution specifically protected child labour.

Constitutional amendments of 1912 provided for recall of judges and for woman suffrage; an amendment (1914, 1916) provided for prohibition but was repealed by referendum in 1932; an attempt to secure local option was defeated in 1950 by popular election. The death penalty, abolished in 1916 as a liberal political issue, was restored in 1918, and in 1933 there was ratified a constitutional amendment making lethal gas the state's mode of capital

NETWORK OF IRRIGATION CANALS IN THE GILA RIVER VALLEY, NEAR SNAKETOWN, BUILT BY THE HOHOKAM IN THE EARLY CENTURIES OF THE CHRISTIAN ERA

After extensive study and photographing by the University of Arizona, the entire Snaketown excavation site was recovered with earth in 1965 to protect it from weather and vandalism

punishment. In 1947 provision was made for the election of the state's two congressmen (three after the 1960 census) by districts instead of at large. Both houses of the Legislature were reapportioned on the basis of population by federal court action in 1966.

Finance and Taxation.—After mid-20th century the state's receipts from all sources amounted to over $450,000,000 annually. Property taxes and sales taxes were the main sources of the state's revenue. General expenditures totaled about $400,000,000 annually, of which about $157,000,000 was spent on education. At the same time the state's gross debt was reduced to less than $50,000. The state's income in the 1960s was about ten times as great as it had been just prior to World War II. In the same period per capita income increased from less than $500 (just over 80% of the national average) to about $2,300, approaching the average for the nation as a whole. Sources of income were manufacturing, mining, crops, tourism, and livestock, in that order. Annual income from the tourist industry had reached $250,000,000 by 1960.

POPULATION

General.—The population of Arizona in 1870 (the first census after the state was incorporated as a territory, 1863) was less than 10,000. By the beginning of the 20th century it was more than 122,931. By 1920 (the first census after the state entered the Union) it had almost tripled and totaled 334,167; the population ranked 45th among the states and was two-thirds rural. During the succeeding 20 years Arizona's population increased gradually; by 1940 it was 499,261, still ranked 45th in the Union and was still two-thirds rural. The state's rate of growth increased markedly after World War II, primarily because of increased industrialization. By 1950 the population totaled 749,587, ranked 37th in the Union and was 55.5% urban. Continuing its rapid growth, the state's population exceeded 1,000,000 after mid-20th century. By 1960 it totaled 1,302,161, ranked 35th in the union and was 74.5% urban. Always one of the most sparsely settled of the United States, there were only 11.4 residents per square mile in 1960. Only New Mexico, Montana, Wyoming, Nevada, and Alaska were less densely populated. In 1960 the population of the state was distributed by colour and nativity as follows: 72.2% native white; 17.6% foreign-born white; and 10.2% nonwhite (Indians 6.9%; Negroes 3.3%). Phoenix and Tucson (*qq.v.*) are the only standard metropolitan statistical areas.

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

Indians.—The Indian population has increased steadily since 1900, but its proportion relative to that of the state as a whole has decreased from more than 20% in 1900 to less than 10% by mid-20th century. Nevertheless Arizona's Indian population was larger than that of any state in the union.

The Indians are organized in 15 tribes, divided into three language groups: Athabascan (Navaho and Apache); Yuman (Mohave, Yuma, Cocopa, Maricopa, Walapai, Yavapai, and Havasupai); Uto-Aztecan (Pima, Papago, Hopi, Paiute, Chemehuevi, and Yaqui). The Pimas and Papagoes figured much in early Arizona history; the Hopis or Moquis are of unusual interest for their prehistoric culture (Tusayan); the Navahos and kindred Apaches were perhaps the most relentless and savage of Indian warriors.

After 1900 a few hundred Yaquis, because of difficulties with the Mexican government, settled in southern Arizona.

The 19 Indian reservations in the state occupy a total of 30,845 sq.mi., slightly more than 25% of Arizona land. The largest is the Navaho reservation in northeastern Arizona. It is a huge, barren area in which the nomadic Navahos raise a few goats and sheep. During the uranium rush of the late 1940s and the 1950s, rich deposits were found on their land. There has also been considerable prospecting for oil in the area. The Hopi reservation lies in the middle of the Navaho tract and is surrounded by it. The Apaches occupy two reservations in the east-central portion of the state, their lands varying from warm valleys to high mountains. The several reservations along the Colorado River provide potentially rich agricultural lands, as do those in the irrigated central valleys. Most of these lands are leased to large farm operators. By far the most picturesque reservation is that in Havasu Canyon, a deep and colourful adjunct to the Grand Canyon of the Colorado. It is reached only by a narrow trail.

EDUCATION

A few school districts of Arizona were established as early as 1864, and a definite public-school system was adopted in 1871. At the time of statehood (1912) land grants of more than one-ninth of the state's area were made for education. Public-school education was made available to pupils between 6 and 21 years of age, and from 1921 compulsory attendance was required of pupils between 8 and 16 years of age. In 1936 requirements for elementary teaching certificates were designated as four years beyond high school, and for high-school teachers, five years. Because of its climate, many private schools have been located in Arizona. In the 1960s there were 58 federal schools for Indians (34 day schools, 17 boarding schools, and 7 boarding-day schools) with an enrollment of about 7,500. In addition there were Indians in attendance at public schools and mission schools.

The Arizona State Industrial School for boys was located at Ft. Grant in 1913, more than half the inmates being of Mexican-American descent. The Arizona State School for Deaf and Blind was established at Tucson in 1910. There were two public junior colleges, at Thatcher and Phoenix; Northern Arizona University, formerly Arizona State College, at Flagstaff (1899); and Arizona State University at Tempe (1885). The University of Arizona at Tucson (1885), has its agricultural experiment station, Steward Observatory, Arizona Bureau of Mines, State Museum, University Extension Division, and Agricultural Extension Service all on the campus; six agricultural research centres, an archaeological field school, and a summer session in Guadalajara, Mex. In 1945 the three state institutions of higher learning were brought under one board of regents. Near Glendale is the American Institute for Foreign Trade offering bachelor's and master's degrees in foreign trade.

THE ECONOMY

Agriculture.—Because of the long seasons, semitropical climate, and irrigation, farming in Arizona has been varied and intensive. Arizona derives most of its agricultural income from crops, which were followed in value by truck farming and livestock raising. Crops include dates, cotton lint and cottonseed, alfalfa (which yields four to seven cuttings a year), hay, barley, flaxseed, grain sorghums, potatoes, wheat, grapefruit, and oranges. Cotton was first grown commercially in the state just before World War I, but by mid-20th century it was Arizona's most important cash crop. In the 1960s only about 14% (approximately 10,000,000 ac.) of Arizona land was privately owned. The federal government owned about 45%, and held in trust for Indians about 26%. The remaining 14% was state owned.

Eight national forests, which occupied a total of about one-sixth of Arizona's area, yielded an annual crop of about 175,000,000 bd.ft. of timber. State and private land yielded an additional annual crop of about 100,000,000 bd.ft.

Industry.—Because of high cost of power, manufacturing in Arizona has not been a leading industry, smelting and sawmills being the most important. Other establishments were brick kilns, concrete block producers, cottonseed oil and cottonseed meal factories, flour mills, lime kilns, canning and dried fruit factories, and mattress factories. Manufacturing products included electronic devices and components, aircraft and parts, and machine tools.

Minerals.—Mining is the leading industry of Arizona. Contrary to tradition, there is no evidence that mining was practised except to a very limited extent by aborigines, Spanish conquistadors, or Jesuits. In 1738 an extraordinary deposit of silver nuggets, quickly exhausted (1741), was discovered at Arizona. At the end of the 18th century the Mexicans considerably developed the mines in the southeast. The second half of the 19th century witnessed several great finds: first, of gold placers on the lower Gila and Colorado (1858–69); later, of lodes at Tombstone, which flourished from 1879 to 1886 then decayed, but in 1905 had again become the centre of important mining interests; and still later, of copper at Jerome and around Bisbee. Several of the Arizona copper mines are among the greatest in the world. The Copper Queen at Bisbee from 1880 to 1902 produced 378,047,210 lb. of crude copper, which was then practically the total output of the territory. Other valuable mines were developed later; the Ajo, Morenci, and Jerome districts are secondary to Bisbee.

Important mines of gold and silver, considerable deposits of wolframite (chief ore of tungsten), valuable ores of molybdenum and vanadium, and quarries of onyx marble are also worked. Low-grade coal deposits occur in the east central part of the state and near the junction of the Gila and San Pedro rivers. Fine gems of peridot (gem olivine), garnet, and turquoise have also been found there.

In the 1960s Arizona was the nation's leader in the value of production of nonferrous metals. The principal mining products are copper, sand and gravel, molybdenum, silver, and zinc.

Transportation.—Until railroads reached the territory in the 1880s, Arizona was accessible from the east only by the sea voyage around Cape Horn and then across southern California or, from east or west, by a difficult and perilous overland trek by horse or wagon. For more than 40 years after their arrival, the railroads remained the principal means of transportation throughout the state. The state was served by two transcontinental railways, the Atchison, Topeka and Santa Fe in the north and the Southern Pacific in the south; in the 1960s there were about 2,000 mi. of railroad trackage.

Arizona lagged behind most of the United States in its use of automobiles. The expense of highway construction in the deserts and mountains was so great, and the state so sparsely settled, that by the early 1920s only about 250 mi. of improved roads carried motor traffic. By the late 1960s, however, there were about 40,000 mi. in the federal, state, and county road systems and the ratio of automobiles to people was high. Four east-west transcontinental highways and one north-south transcontinental highway crossed Arizona. The state was served by commercial airlines, and several transcontinental and interurban bus lines.

(H. A. H.; E. H. P.)

ARK, derived from Lat. *arca* ("container," "box"), is used exclusively in biblical contexts, where it represents two different

Hebrew words: *tebah* and *aron*.

Tebah.—This word, borrowed from Egyptian, means either a box or a palace (as a rectangular building with a flat roof). *Tebah* in Ex. ii, 3 means "box"; the infant Moses was put into a box of calked papyrus. The story of the flood uses the word in the second sense of "palace" for Noah's ark (Gen. vi–ix). Here *tebah* is a house made of wood that can float. While the older Yahwist tradition (*see* PENTATEUCH) does not describe Noah's ark in detail, the later Priestly version gives detailed information, perhaps based on a regained knowledge of the Babylonian prototype. The ark was built from wood timbers or planks, calked with pitch on the outside. It had three stories and a door at the side. The model for the story of the ark is found in the 11th tablet of the Gilgamesh (*q.v.*) epic. Here too the ark is a box, synonymous with both a ship and a palace; it is even larger than in the biblical story, with six stories.

Aron.—This Hebrew word is common to other Semitic languages and also exists in Akkadian as *'aranu*. It occurs in three usages. There is a single example of it describing the coffin in which Joseph's body is said to have been brought from Egypt to Shechem (Gen. l, 26). The narrator evidently knew Egyptian wooden coffins, which were chestlike. Further, in a historically reliable account in II Kings xii, 9, 10 (in Hebrew text verses 10, 11; *cf.* II Chron. xxiv, 8–11), *aron* is applied to a wooden chest with a hole in the lid for the collecting of money.

Ark as a Holy Vessel.—In contrast to these two rare mentions of the chest there are nearly 200 references in the Old Testament to a holy vessel closely connected with the presence of the God of Israel. Where the context is clear (*e.g.*, Num. x, 35 ff.; Josh. iv, 10) it is simply called "the ark." Usually, however, it is distinguished from secular chests by a descriptive word. Even these epithets show that various conceptions were associated with the ark. There are five such titles: the ark of God (*e.g.*, I Sam. iv, 13), the ark of the God of Israel (*e.g.*, I Sam. v, 7), the ark of the Lord (Yahweh; *e.g.*, I Sam. iv, 6), the ark of the covenant of the Lord (*e.g.*, Deut. x, 8; xxxi, 9; *cf.* Jer. iii, 16) and the ark of the testimony (especially Ex. xxv, 21 ff.). The significance of these various titles will be discussed in the course of considering the history of the ark.

The first question is the ark's appearance. It is described only once, in the Priestly narrative (Ex. xxv), which dates from a period when the ark was no longer in existence, since it was lost during the destruction of Jerusalem by Nebuchadrezzar (587 B.C.). The legend, dating from the 2nd century B.C. and related in II Macc. ii, 4–8, that Jeremiah hid the tabernacle, the altar of incense and the ark in a cave where they would remain until the return of Israel from exile, stresses the continuity of the cult. Rabbinical sources suggest a subterranean chamber under the holy of holies in the Temple or a particular place in the forecourt. In Jer. iii, 16 it is stated that the ark should not be remade after its destruction. Although the description of the ark in the Priestly account in Ex. xxv is not based on personal observation, it is at least founded on a good and early tradition, as is shown particularly by the mention of the *kapporeth* ("mercy seat"). According to Ex. xxv the ark was a chest of acacia wood 2½ cubits long, 1½ cubits wide and 1½ cubits high. The poles supported by rings on the long sides made it possible for the ark to be carried (Ex. xxv, 12–15; *cf.* I Kings viii, 7–8). Although the earlier accounts do not mention the number of the bearers, Josh. iii and II Sam. vi, 13 show that the ark was normally carried; it was the exception for it to be driven (I Sam. vi, 8 ff.; II Sam. vi, 3). The gilding of the ark commanded in Ex. xxv, 11, 13 is unknown to the older tradition (*e.g.*, Deut. x, 3); it is a parallel to the gold of the mercy seat.

The wooden ark doubtless had a lid that could be opened and shut. This is the only explanation for the belief (known at least as early as the pre-exilic period) that the ark was a container in which the tablets containing the ten commandments were kept (*cf.* Deut. x, 1–5). Hence came the title "the ark of the covenant." The Priestly tradition also recognizes the presence of something inside the ark; it is the testimony (of the covenant?), Hebrew *eduth*, which Moses received from God and which he was to put into the ark. Hence in the Priestly traditions the ark is called "the ark of testimony." It would be the two tablets of the decalogue that were in question, not the Pentateuch, for otherwise the name would have been "the ark of the Law" (the Torah).

The Priestly account also is interested in another holy object, the *kapporeth*, a golden slab of the same measurements as the top of the ark, with two golden-winged cherubim at the sides (Ex. xxv, 17–22). The Priestly account shows that the *kapporeth* is not identical with the lid of the ark but is a separate object (*e.g.*, Ex. xxxi, 7; Ex. xxxv, 12; according to Ex. xl, 20 Moses set the *kapporeth* on the ark outside the tabernacle; according to Ex. xxvi, 34 it is only set upon the ark within the holy of holies of the tabernacle). Hence the ark with the *kapporeth* has been very variously reconstructed. An attempt has been made to see behind the text different traditions with perhaps two different conceptions of the position of the cherubim on the ark, but this has met with no success. The presupposition must rather be that behind the Priestly account in I Kings vi, 23–28 lies the description of the great cherubim in the holy of holies of the temple whose task was, according to I Kings viii, 6–7, to cover the ark. Just as the Priestly account of the tabernacle which belonged to the period of the wandering in the wilderness is coloured by detail from the temple of Solomon, so here it places the two cherubim of the temple (which were independent of the ark) in the period of the wandering in the wilderness and by means of the *kapporeth* associates them with the wooden ark. In the same way the cherubim carved on the doors of the temple in I Kings vi, 32, are found again on the curtain in the tabernacle (Ex. xxvi, 31).

History of the Ark.—The early history of the ark before the time of Saul (*cf.* I Sam. iii–vi) is obscure in many respects. Its place of origin is also an open question. It is not clear whether the ark was the holy thing that guaranteed the helping presence of God to the Israelite groups on Sinai and in Kadesh, or whether it was the tabernacle that had this function. The earlier narrators do not know the story of Moses making the ark on Sinai (which appears first in Deut. x, 1–8; *cf.* Ex. xxxvii, 1 ff.); a stone as testimony is mentioned at the assembly at Shechem (Josh. xxiv, 26–27) but not the ark. In Num. x, 35–36 the invocation of God that originally was made before and after a holy war is now associated with the daily setting forth and coming to rest of the ark as God's escort of the people's wanderings.

Although it is not in principle impossible that the wandering tribes of Israel had a wooden ark, it is disconcerting that the earliest title for the ark, in I Sam. iii, 3 is not "the ark of the Lord" but "the ark of God." The origin of the ark outside Israel is stressed by a statement in II Sam. vi, 2: that David fetched the ark of God over which was proclaimed the name of Yahweh Sabaoth, who sits enthroned among the cherubim (*i.e.*, he who—in the holy of holies—reigned over the cherubim). The proclamation of the name was in Israel a legal act that marked the transfer of a person, thing or piece of land into the possession of another. Thus the ark of God is claimed for the great God of Jerusalem, and is thereby taken over by the people of the covenant. The place of the transfer could have been the pre-Israelite holy place of Shiloh (in the area of the tribe of Joseph). The connection with Gilgal near Jericho (Josh. iii–iv) and with Bethel (Judges xx, 26–27), both Benjamite places, could date from before or, more probably, from after the Shiloh period. Later the ark was lost to the Philistines in battle and then given back. After the first stage of its recovery (I Sam. vi), David brought it to Jerusalem (II Sam. vi); there in the city of David the object of reverence which had protective religious power was intended to bind all Israel to the house of David. Thus the ark came too into the holy of holies of the temple of Solomon (I Kings viii, 6).

The conclusion has been drawn, probably correctly, from Ps. xxiv, 7–10, that on certain feast days there were solemn processions in which the ark was carried out of the temple and in again through the gate of the temple forecourt, though the ark is not actually mentioned in this psalm. The kings of Judah no longer took the ark into battle (especially as some of the wars were against the northern kingdom!) as they apparently still did in the time of Saul (I Sam. xiv, 18) and David (II Sam. xi, 11). The theory propounded by W. R. Arnold and H. Gressmann (who

points to I Sam. xiv, 18) that there was an ark in every large holy place in Israel cannot be correct; otherwise it would certainly have been mentioned in I Kings xii, 28 ff. in connection with the rival temples in Bethel and Dan, and King Josiah of Judah would have mentioned the local arks when the local holy places were put down (II Kings xxiii, 4 ff.).

Contents of the Ark.—Those who like J. Morgenstern date the ark from the period of the wanderings in the wilderness postulate primarily an empty chest, which has been compared with the tabernacle that Bedouin tribes set upon a camel. R. H. Kennett supposed that the brazen serpent made by Moses was once kept in the ark (Num. xxi, 4–9). This serpent when placed on a pole would have been of sufficient proportions to fill the ark. It would then have to be assumed that the brazen serpent was removed from the ark when the latter was put in the holy of holies. The ark would then apparently be interpreted as the footstool of Yahweh as he reigned above the cherubim in the temple (*cf.* Ps. xcix, 5; Ps. cxxxii, 7; and I Chron. xxviii, 2. In the latter text the word "and" has to be interpreted as "that is" in order to fit in with this view).

Those who believe with Gressmann that the ark had a Canaanite origin think in terms of two idols, whether representational or not (*cf.* the two tables of the Law). E. Nielsen concludes from *eduth* (ark of testimony) that from the time of David the royal protocol of the kings of Judah was deposited in the ark. In that case, however—and this is a fatal objection—the ark would have lost its protective character. If the ark was not empty in the Canaanite period (but why should it then be a chest with a lid?) then the idol or idols would have been removed in Shiloh or Jerusalem because Yahweh had forbidden idols in the second of the ten commandments (Ex. xx, 4). It could have been said in the 7th century that the two tables of the decalogue were kept in the ark only if it was known that the ark was empty up to that time. As tablets containing laws are not normally concealed but are publicly displayed, it is only possible at the most that the tables were at some time copied (though there is in fact no record of this) and that the old ones were deposited in the ark.

In Jer. iii, 16–17 Jerusalem, as the throne of Yahweh, is placed in antithesis to the ark, which might lead to the conclusion that the empty ark was conceived as being the throne of Yahweh; there were not a few examples in neighbouring lands of empty divine thrones. Empty divine thrones (always with high backs), with cherubim on the sides, seem to provide a good parallel, but the prototype for these divine thrones is always a king's throne. The chief objection to this widely held view derives from the description and form of the ark. If it was a throne, why is it called a chest? If it was a throne, why is it twice as long as it is broad, especially as it was placed in the holy of holies (as I Kings viii, 8 shows) with the narrow side to the front? The ark, that is to say a chest, was rather given over to Yahweh, who reigned among the cherubim (II Sam. vi, 2); that is to say, Yahweh had this title before there was an ark for him. He was given the title because of the great cherubim that stood in the holy of holies, above whom he was seen by Isaiah in his vision, reigning as a king (Isa. vi). And the prophet Ezekiel (Ezek. i ff.) sees the glory of Yahweh above a vehicle with four cherubim (called *merkava* in Jewish tradition), and not above the ark, just as the *kapporeth* (*see* above) was also not a part of the ark.

Ark in Later Judaism.—Both the Hebrew words for ark, in association with the word for holiness, are used as descriptions of the holy shrine in the synagogue where the encased rolls of the Law were kept. In this sense the Torah shrine is the successor of the "ark of the covenant," the contents of which were believed to be the two tables of the Law. The ark of Noah is interpreted allegorically by Philo.

Ark of Noah in Christian Tradition.—As Noah was saved by the ark from the waters of death, so, in the catacomb paintings, the dead person whose soul is to be saved is represented as praying in the ark. In addition to this symbolism of salvation there is also baptismal symbolism, going back to I Pet. iii, 20, whereby the ark is the type of the saving church, as for instance in Cyprian, Jerome and Augustine. On a 4th-century sarcophagus in Trier the ark embodies the eternal church, crowned with victory. *See* FLOOD (IN RELIGION AND MYTH).

(KU. G.)

ARKANSAS, once called the "Bear state" and later the "Wonder state" and renamed the "Land of Opportunity" by the 1953 general assembly, is one of the south central states of the United States. Situated between 33° and 36° 30′ N. lat. and 89° 40′ and 94° 42′ W., it is bounded by Missouri on the north, Tennessee and Mississippi on the east, Louisiana on the south, Texas on the southwest and Oklahoma on the west. In size, it ranks 27th among the states with an area of 53,104 sq.mi., including 605 sq.mi. of water surface. The capital city is Little Rock. Arkansas entered the Union, as the 25th state, on June 15, 1836. The state flower is the apple blossom, the official tree is the short-leaf pine and the mockingbird is the state bird. The official state flag is a blue-bordered white diamond on a rectangular field of red; the border contains 25 stars, the diamond has 4 stars.

PHYSICAL GEOGRAPHY

Topography.—Arkansas is in the drainage basin of the lower Mississippi valley; the Mississippi river forms the eastern boundary of the state and the Arkansas, the largest river, bisects the state from northwest to southeast. Other major tributaries include the Red, the White, the Ouachita and the St. Francis rivers. The state falls within two major physiographic divisions of the southern United States, the line of demarcation extending diagonally from the northeast corner to the southwest; on the east and south is the low gulf coastal plain; to the west and north are the interior highlands. The gulf coastal plain is composed of two parts: the rich Mississippi alluvial plain along the eastern boundary of the state, with elevations of 100–300 ft.; and the west gulf coastal plain in the southwest, a more hilly and generally less fertile section with an elevation of 200–700 ft. An unusual feature of the Mississippi alluvial plain is the loessial Crowley's ridge, which describes an arc from Phillips county north into Missouri. The Ozark plateau and the Ouachita province comprise the northern and western parts of the state. The Ozark plateau is made up of the Boston mountains, the highest large land area in the state, with an average elevation of 2,000 ft. and with peaks above 2,800 ft.; the Springfield plateau, a gently rolling plateau north of the irregular north-facing escarpment of the Boston mountains which ranges from 1,250 to 1,700 ft. above sea level; and the Salem plateau, a rough to rolling country averaging 1,250 ft. in elevation on the northern boundary of the state. The Ouachita province in the west-central section of the state is lower, but the formations were raised by similar compressive forces. The rocks of the highlands are chiefly sandstone, shale, limestone and dolomite; in the lowlands, clay, sand, marl and chalk. The soils are extremely variable in composition, ranging from the heavy alluvial soils of the Mississippi alluvial plain to the light sandy soils of the Ouachita and Ozark uplands.

Climate.—The climate is temperate, the monthly average maximum and minimum temperatures ranging from 72°–50° F. in west Arkansas to 70°–53° F. in the east. Temperatures exceed 100° F. at times in July and August, and readings of 0° F. occur occasionally in the north in January and February. Normal precipitation is 48.63 in.; annual snowfall averages 2.8 to 10.4 in., and humidity ranges from 60% in December and January to 45% in July and August. An average of nine tornadoes occur each year, most of

them limited by short, extremely narrow paths.

Plants and Animals.—The state possesses rich and varied plant and animal life, with one-fourth of its area actually covered by standing timber and more than 2,000,000 ac. in the Ozark and Ouachita national forests. There are at least 210 species of trees, the oak group being the largest with 43 forms, the hickory with 21 and maple with 11. Of great decorative value are the redbud, holly, dogwood, buckeye, wild crab apple and other woody plants. Approximately 250 kinds of grasses, 200 different sedges and 24 different rushes are found in the state. The more important animals are deer, turkey, squirrel, rabbit, the fur-bearing skunk, opossum, mink, muskrat and red and gray foxes. Among the kinds of fish found are the large mouth bass, the small mouth bass, bream, crappie, buffalo, drum, catfish and the predatory gar. Bird life is prolific: among the 312 species and subspecies there are migrants, such as the canvasback and mallard ducks along the Mississippi flyway in the eastern counties; predators, such as hawks, owls and eagles; pests, such as crows, starlings and English sparrows; and quail, snipe, blackbirds, thrushes and warblers.

State and National Parks.—Hot Springs National park, in west central Arkansas, contains about 1,000 ac.; its 47 mineral hot springs are said to have therapeutic value. The state park system has achieved a delightful mixture of the rustic and the modern and provides facilities for camping, boating, swimming, fishing and hiking in some of the state's most beautiful sections. Most of the state parks have cottages equipped for light housekeeping. The 12 state parks and 4 state memorials attract more than 1,000,000 visitors annually. The state parks are named Petit Jean, Buffalo River, Devil's Den, Queen Wilhelmina, Lake Chicot, Lake Catherine, Mount Nebo, Crowley's Ridge, Bull Shoals, Arkansas Post, Lake Ouachita and Daisy. The state memorials, each commemorating a historical event or person, are Hampson, Herman Davis, Davidsonville and Carrollton. In 1960 the Pea Ridge battlefield in northwest Arkansas was designated a national military park by the national park service. In Little Rock may be seen the three capitol buildings that have served Arkansas as seats of government since 1821. The Territorial Restoration includes governmental offices from 1821 to 1836 and the homes of some of the state's earliest men of prominence. The Old State house, which was the state capitol from 1836 until the present capitol was occupied in 1909, is a beautiful example of civic architecture of that period; it contains displays depicting Arkansas' early days. At Fort Smith, the courtroom and gallows of U.S. district judge, Isaac Parker, known as the "hanging judge" because of his strict enforcement of the law, has been restored. Ouachita National forest and Ozark National forest provide scenic beauty and are popular recreation places. Near Murfreesboro, a portion of the only known diamond field in North America is open to the public and any diamonds found there may be kept. Fishing, boating and other aquatic sports are practised on the state's many lakes, the most notable of which are Lake Norfork, Bull Shoals lake, Lake Ouachita, Lake Nimrod, Lake Greeson, Lake Hamilton, Lake Catherine, Lake Conway and Lake Chicot.

HISTORY

Earliest Inhabitants.—Arkansas' earliest inhabitants, the pre-Columbian bluff dwellers, flourished about A.D. 500. Burial remains in Washington county, in the northwestern part of the state, indicate that the bluff dwellers planted corn, beans, pumpkins, sunflowers and other plants, and that they were adept at fishing, weaving, pottery making and chipping stones into awls and other tools. They used bows and arrows, darts and a throwing stick similar to the Aztec *atlatl* in hunting deer, buffalo and other game. Later, mound builders appeared along the Mississippi river and constructed sepulchral mounds containing effigy vessels, pipes, shells, implements and skeletons.

Exploration and Settlement.—Hernando de Soto, the first European explorer to enter Arkansas, crossed the Mississippi near Sunflower landing June 29, 1541. Search for food and gold took the Spaniards through central Arkansas, across the Arkansas river, to Hot Springs and down the Ouachita river to a site near Camden where they wintered. De Soto died the following spring. The French Jesuit missionary, Jacques Marquette, along with Louis Jolliet and five companions in 1673 descended the Mississippi to the mouth of the Arkansas river and spent a month among the Arkansea Indians. The explorers discovered that the Mississippi flowed into the Gulf of Mexico instead of into the Pacific ocean. Warned of hostile Indians downstream, Marquette and Jolliet returned to Canada.

The explorations of René Robert Cavelier, sieur de la Salle, who took formal possession of the territory for Louis XIV of France, April 9, 1682, led to the first permanent white settlement in Arkansas. La Salle's lieutenant, Henri de Tonti, left six men to build a fort near the mouth of the Arkansas in 1686, while he led a search party for La Salle who had, however, been killed in Texas. The fort became Arkansas Post, and served as a link between the French settlements of the upper Mississippi and those in Louisiana until John Law's Company of the West received a monopoly in the territory in 1717. Law's duchy of Arkansas, as it was called, attracted slaveholding colonists from the Palatinate in northern Germany, but the bursting of the "Mississippi Bubble" (for details of "Mississippi Bubble," *see* LAW, JOHN), caused them to withdraw to Louisiana. Arkansas Post remained a trading centre and a Jesuit mission under Bernard de la Harpe who ascended the Arkansas river beyond the present site of Little Rock in 1722.

The territory was ceded to Spain by France in 1763. Subsequently, the Spanish governors made land grants along the west bank of the Mississippi to U.S. settlers in order to populate the country, yet the 1785 census showed only 196 persons and that of 1799 only 368 living there. Spain was forced to return the territory to France in 1800; the United States acquired it as part of the Louisiana Purchase in 1803. Arkansas was an administrative subdivision of Louisiana until 1812, when congress attached the district to the territory of Missouri. The territory of Arkansas was created by congress in 1819 with the capital at Arkansas Post; two years later, Little Rock became the capital city.

Statehood.—Arkansas was admitted to the union in 1836 as a slave state, but the lawless spirit of the frontier continued, especially along the western border. When the Mexican War was declared in 1846, Arkansas oversubscribed its quota of volunteers and former Gov. Archibald Yell led an Arkansas regiment until his death at Buena Vista, Mex. Politically, the Masons under Albert Pike and the Roman Catholics under Bishop Andrew Byrne joined to squelch the Know-Nothing party (*q.v.*). The Butterfield stage line was extended from St. Louis, Mo., through western Arkansas in 1858 and a telegraph line connected Fayetteville, Ark., and St. Louis, in 1860.

The Civil War.—With many of its settlers natives of southern states and with nearly one-fourth of its inhabitants slaves, Arkansas was inevitably drawn into the secession crisis. Arkansans were alarmed by the reinforcement of the federal garrison at Little Rock in Nov. 1860, and state troops took over the post Feb. 8, 1861. In the convention that met March 4, 1861 to consider secession, David Walker, an antisecessionist, was elected president and Elias C. Boudinot, a half-Cherokee slaveholder, was named secretary. Immediate secession was rejected, but a referendum was asked to determine whether or not Arkansas should be represented at an impending conference of the border states. The Arkansas convention adjourned March 21 and before it reconvened the bombardment and surrender of Fort Sumter on April 12–14 had opened hostilities. When the convention met again on May 6 it voted for secession 69 to 1 and Arkansas joined the Confederacy on May 16, 1861.

About 58,000 Arkansas men joined the Confederate army and perhaps 6,000 served in the Union forces. Arkansas was the scene of several battles during the course of the war. Gen. Samuel R. Curtis' Union army defeated Gen. Earl Van Dorn's Confederate troops in a bloody battle at Pea Ridge (Elkhorn tavern) on March 7–8, 1862. At Prairie Grove on Dec. 7, 1862, Confederate Gen. Thomas C. Hindman tried to block the juncture of the Union forces of Gen. James G. Blunt with those of Gen. Francis J. Herron, but Hindman was forced to withdraw causing northwest Arkansas to remain in federal hands. Confederate Gen. T. H.

Holmes was repulsed at Helena July 4, 1863, by Curtis. When Little Rock fell to Gen. Frederick Steele Sept. 10, 1863, a Union governor was installed although Confederate Gov. Harris Flanagin also held office at the provisional capital at Washington in south Arkansas. After occupation by Union forces, Union sympathizers elected a Republican governor, repudiated the secession ordinance and Confederate war debts, ratified the 13th amendment and set up an orderly government in 1864. The 1866–67 legislature, made up largely of former secessionists, nullified much of this work, however.

Reconstruction.—Following the Confederate surrender, the state was controlled by the Federal army as part of the 4th military district. In Dec. 1867 the Republicans elected a constitutional convention and the Reconstruction government took office in 1868. It drew up a new constitution and provided for the registration of voters, the creation of public schools, the adoption of the 14th amendment and the establishment of a school for the deaf and an industrial university that later became the University of Arkansas. Arkansas was readmitted to the union June 22, 1868, over Pres. Andrew Johnson's veto.

Republicans remained in control until 1874. They suppressed the Ku Klux Klan, supported free schools and protected the rights of former slaves, but plunged the state into debt with exorbitant railway and levee grants. However, the state supreme court in 1877 ruled that the state was not responsible for railroad bonds not approved by popular vote, and in 1884 a constitutional amendment canceling bonded debts of the Reconstruction legislatures of 1868, 1869 and 1871 was approved.

The struggle between Joseph Brooks and Elisha Baxter, rivals for governor, climaxed the Reconstruction era. Brooks, at one time a supporter of Gov. Powell Clayton, began his campaign to depose Clayton in 1871 by forming a coalition of radical Republicans and Democrats. Clayton, however, who had decided to run for the U.S. senate, had chosen Baxter to be his successor as governor. Though Brooks probably received the larger vote, the legislature declared Baxter elected in 1873. Baxter gained the support of the Democrats, but lost that of the Republicans when he refused to countenance further exploitation of the state. In April 1874, Brooks got a circuit court writ of ouster and took possession of the capitol, proclaiming himself governor. Baxter retaliated by organizing an army and appealing to Pres. U. S. Grant for recognition. Brooks also organized a militia with the support of Arkansas's two senators. President Grant, who favoured Brooks, ordered troops to maintain the peace and called on the state legislature to settle the dispute. After a month, during which 20 men were killed in skirmishes, the Democratic legislature recognized Baxter as governor. The legislature then called a constitutional convention that limited the patronage powers of the governor, set his term of office at two years and reserved to itself the suspension of the writ of habeas corpus.

Return to One-Party Control.—Beginning with the administration of Gov. Augustus H. Garland in 1874, the Democratic party and the state government remained in the hands of former secessionists for a generation thereafter. Democratic party control has seldom been threatened since that time. In the 1880s farm and labour groups formed the Agricultural Wheel, a new political party, and came within 15,000 votes of electing a governor in 1888. Shortly after the return of the dissidents to the Democratic party, state politics came to be dominated by Jeff Davis (1862–1913), a namesake of the Confederate president. Though flamboyant in manner and accused of demagoguery by his opponents, he achieved educational and penal reforms and all but retired the bonded debt of the state during his terms as governor (1901–07).

There was general excitement at the discovery of diamonds in Pike county in 1906 (the only known deposits in North America), and the oil boom at El Dorado and Smackover in 1921–22 gave rise to a new industry. Bauxite, which had been discovered in 1887 only began to be exploited commercially in the 1940s, making Arkansas an important centre of the aluminum industry. A disastrous flood in 1927, which inundated one-fifth of the state's area, emphasized the need for control of the Mississippi river. Congress initiated such a program the following year.

Two Arkansas political figures became nationally prominent in the late 1920s and early 1930s. Sen. Joseph T. Robinson, who had taken Jeff Davis' seat in the U.S. senate, was the Democratic candidate for vice-president in 1928. In 1932 Hattie Caraway, the widow of Sen. Thaddeus H. Caraway (1871–1931), became the first woman ever to be elected to the U.S. senate.

A severe drought in 1930 aggravated the impact of the depression. State action to alleviate conditions was reinforced by federal programs including aid for the construction of new schoolhouses, courthouses and other public buildings. Through the 1930s and 1940s state politics were concerned largely with the creation of administrative and welfare agencies, the refunding of highway bonds and, after the repeal of national prohibition, the adoption of local option liquor laws. Liquor taxes and a new sales tax brought added revenue for expanding services. During World War II thousands of men received their basic training at Camp Robinson; Camp Chaffee was established near Fort Smith and a number of airfields and proving grounds were placed in operation. Politically, Democrats remained in control of the state government and Arkansas voters continued to support the Democratic presidential candidates.

After the war personalities dominated state politics more than issues. Then, in 1948, Sidney McMath was elected to succeed the conservative Gov. Ben T. Laney. He was re-elected in 1950 but lost a third term when Francis A. Cherry was swept into office as a reform candidate. Cherry's administration was notable for a lack of partisan politics, which was largely responsible for his being the second Arkansas governor to be defeated for a second term.

Cherry was succeeded in 1954 by Orval E. Faubus, a publisher, who later became the first Arkansas governor to win a sixth term. Faubus' administration was marked by industrial progress and the passage of tax increases to improve the schools and other services until, in 1957, the school integration issue became a chief concern in the state.

Integration Crisis.—After the 1954 U.S. supreme court ruling that racial segregation in public schools was unconstitutional, that state became the focus of international attention. Schools in six Arkansas towns with small Negro populations desegregated with little or no incident, but in Sept. 1957, on the eve of the opening of Little Rock Central high school on an integrated basis, Governor Faubus ordered the national guard to prevent integration and to preserve order. The troops, on Faubus' orders, barred from the school the nine Negro pupils who had enrolled. On Sept. 22, a U.S. judge ordered the removal of the troops. The Negroes' attempt to enter their classes was opposed by a segregationist mob and police were called to escort the students to safety. The next day, Pres. Dwight D. Eisenhower ordered into federal service the entire Arkansas national guard and sent 1,000 federal troops to Little Rock to enforce U.S. court orders, and to enable the Negroes to complete the school term.

In the summer of 1958, Governor Faubus won Democratic renomination for a third term by an unprecedented majority. The Little Rock school board asked a 30-month delay in desegregation, but was refused by the U.S. supreme court causing Governor Faubus to call a special session of the legislature. It passed, at the governor's urging, a package of segregation bills, including one used to close all the public high schools in Little Rock. Thus, all students were compelled to transfer to schools elsewhere, to attend private schools or simply to remain out of school. In 1959 the Little Rock high schools were reopened with token integration. An opening day mob was quickly dispersed by police and an uneasy truce between segregationists and integrationists was effected.

Governor Faubus was reelected to his unprecedented sixth term in 1964. He retired in 1966, the Democratic nomination going to an archsegregationist, James Johnson, and the voters, for the first time since Reconstruction, elected a Republican, Winthrop Rockefeller, as governor.

GOVERNMENT

The government of Arkansas is based upon the provisions of the constitution of 1874 and its amendments. The governor, who must

be at least 30 years old and a resident for 7 years, has the power to commute sentences or pardon in all cases except those involving treason and impeachment. His veto powers include the veto of specific items in appropriation bills.

The bicameral legislature is composed of 35 senators elected for 4 years and 100 representatives who serve 2 years. The regular biennial session of 60 days may be extended by a two-thirds vote of each house, but the governor may call special sessions at any time. Constitutional amendments may be proposed by a simple majority of both houses or by initiative petition. The seven members of the supreme court are elected for eight years. All elected state officials may succeed themselves. The franchise is extended to citizens 21 years or older who have lived in the state 12 months.

Denial of employment because of membership in or resignation from a labour union is prohibited.

Finance and Taxation.—In the second half of the 20th century, the state's receipts from general and special sources amounted to approximately $150,000,000 annually. In addition, the state received about $60,000,000 annually in federal grants. The major portion of the state's revenues was derived from the sales tax, the gasoline tax, the state income tax, the alcoholic beverage tax and automobile licence fees. The state's expenditures totaled nearly $250,000,000 annually and the state's net debt stood at $80,000,000. The state's income was about twice as great as it had been prior to World War II, but its per capita income remained among the lowest in the union, only one or two states having a lower statistic. Arkansas was spending 35.5% of its revenues on education, about 23% on highways, 13% on public welfare and 7% on health and hospitals.

POPULATION

The population of Arkansas in 1840, the first federal census in which it figured as a state, was 97,574. Its population ranked 26th among the 30 states and territories that then composed the union and was classified as 100% rural. The next decade was the period of most rapid growth after acquiring statehood—the population increased 115% between 1840 and 1850. In 1860, immediately before the Civil War, the state had a population of 435,450, of whom about one-fourth were Negro slaves. It was then the 25th most populous state, and was still practically 100% rural. At the beginning of the 20th century, the state remained 25th in rank of population with a total of 1,311,564 persons according to the census of 1900. It was still largely rural in character: 91.5% of the people were classified as nonurban dwellers. From 1910, the nonwhite population began a slow, but steady decline which continued through the 1960 census. In 1910 the nonwhite population was 28.1% of the total, but by 1950 had declined to 22.3%. The 1950 population showed a total of 1,909,511 persons living within the state making Arkansas the 30th in size of population among the states. The 1950 figure showed a decline of 2.1% from that for 1940 (1,949,387). The previous decade, from 1930 to 1940, had the slowest population growth in the state's history. By 1950 the rural population had declined to 67% of the total. The Little Rock-North Little Rock area was the state's only standard metropolitan statistical area in 1950; it contained 10.3% of the total population. By 1960 there were 3 standard metropolitan statistical areas and they housed 18.9% of the total population. In 1960 Arkansas had a population of 1,786,272, a decrease of 123,239 or 6.5% from 1950. Among the reasons cited for the state's decline in population since 1940 are the mechanization of agriculture which resulted in bigger farms and, until the mid-1950s, a lag in the state's industrial development. Many of the persons who left the state were Negroes; others were marginal farmers and young people, especially college graduates, who were looking for a higher income.

The population per square mile in 1960 was 33.6, as compared with 49.7 for the U.S. as a whole. The 1960 urban population was 765,303 or 42.8% of the total, continuing the trend toward increasing urban residence. Distribution by colour and nativity according to the 1960 census was as follows: 77.8% native white; 0.4% foreign-born white; and 21.8% nonwhite, practically all Negro. In line with the rest of the U.S. the percentage of persons 65 years old or over was increasing, being 10.6% in 1960. The percentage of the population 14 years old and over that was in the labour force (48.8% in 1960) was steadily decreasing, the result of prolonged schooling for that age group.

*Populations are reported as constituted at date of each census.
Note: Dash indicates place did not exist during reported census, or data not available.

EDUCATION

Historical.—When Arkansas was admitted to the union, congress reserved the customary 16th section of each township of the public lands for school property and donated 72 sections (46,080 ac.) for a state university. However, early legislatures sold both the school and university lands to pay current expenses leaving public education to private academies. After the Civil War, the Reconstruction government established free public schools and a state university. Free textbooks were first provided in 1936 and a teacher retirement plan was initiated in 1937. In the 1950s public school enrollment was 98.3% of the school population; the average term was 173 days; and teachers received salaries averaging $2,469, and the expenditure per pupil in average daily attendance was $169, compared with a national average of nearly $300. Nevertheless, the percentage of state revenues spent for education was more than twice the pre-World War II percentage.

Schools.—The University of Arkansas, a land-grant university founded in 1871, has its principal campus at Fayetteville, where there are colleges of arts and sciences, education, engineering, agriculture, home economics and business administration, the school of law, the graduate school and the general extension service. The university's medical units, its graduate extension centre and graduate institute of technology are at Little Rock. Arkansas Agricultural, Mechanical and Normal college at Pine Bluff, founded in 1873, is the state's college for Negroes. Arkansas State Teachers college at Conway was founded in 1907. In 1925 the state's four agricultural high schools became Arkansas Polytechnic college (Russellville), Arkansas State college (Jonesboro), Arkansas State Agricultural and Mechanical college (name changed to Southern State college in 1951; Magnolia) and Arkansas Agricultural and Mechanical college (Monticello), respectively. In 1929, when Henderson-Brown college merged into Hendrix college (1884), a Methodist school at Conway, Henderson State Teachers college was established on the former Henderson-Brown campus at Arkadelphia.

Typical Ozark mountain scene near Winslow, northwestern Arkansas

The Old Statehouse, Little Rock, was constructed in the 1830s and served as the state capitol until 1909. In 1921 it became the War Memorial building

Cattle pens and silos at Winrock, a model farm near Morrilton. Purebred Santa Gertrudis cattle are raised on the farm, owned by Winthrop Rockefeller

Private denominational colleges, in addition to Hendrix, include Ouachita Baptist college (1886) at Arkadelphia; the College of the Ozarks, Presbyterian (U.S.A.; 1891) at Clarksville; John Brown university, interdenominational (1919), at Siloam Springs; Harding college, Church of Christ (1924), at Searcy; Arkansas college, Presbyterian (U.S.; 1871), at Batesville; Conway Baptist college (1952), at Conway and Southern Baptist college (1941), at Walnut Ridge. Little Rock university (1927) is privately endowed. Negro denominational colleges include Philander Smith college (1868), Methodist, at Little Rock; Arkansas Baptist college (1884) at Little Rock; and Shorter college, African Methodist Episcopal (1886), at North Little Rock. The state maintains schools for the deaf and the blind at Little Rock, and in 1957 started a school for retarded children at Conway.

HEALTH AND WELFARE

The state maintains a tuberculosis sanatorium for white patients at Booneville and one for Negroes at Alexander; state mental hospitals are located at Little Rock and Benton. The state's welfare expenditures included aid to the aged, the blind, the disabled and dependent children. The state's penal system includes Tucker and Cummins prison farms for male criminals, industrial schools for delinquent boys at Pine Bluff (white) and at Wrightsville (Negro) and delinquent girls at Alexander (white) and at Fargo (Negro). There are facilities for women offenders at the Cummins prison farm. There are approximately 1,000 health and welfare agencies about one-half of which are public.

THE ECONOMY

In the second half of the 20th century, Arkansas remained primarily an agricultural state, but there was a definite trend toward industrialization. After 1940 the mechanization of agriculture resulted in larger farms and a smaller farm population. Also, the steady migration from farms to the urban centres resulted in population losses of as much as 30% in some counties and caused the state's population to decline during the 1950s (see *Population* above). To combat this decline the legislature established the Arkansas Industrial Development commission in 1955 to co-ordinate the work of about 100 local groups in attracting industry. The commission gathered information on desirable sites for new industrial plants and offered help to areas seeking industries. As a result, by 1960 there were almost 100,000 workers in more than 3,000 industrial plants in the state, and new jobs were being created at the rate of about 10,000 a year. Furthermore, laws were adopted permitting municipalities and counties to vote bond issues to provide buildings for industrial plants.

Agriculture.—The estimated 150,000 farms in the state were valued at about $1,225,000,000 in the 1960s. Farm owners cultivated more than 50% of the total acreage compared with 37% in 1930. Cotton, historically the state's principal crop, began to decrease in importance in the 1950s and by the 1960s, although still the state's largest money crop, had been surpassed by soybeans in acreage cultivated. Arkansas produced 60,000 bu. of soybeans in 1928, but 5,000,000 bu. in 1954 and more than 50,000,000 bu. by the 1960s. Mississippi county, formerly a major centre of cotton production, had become the nation's biggest producer of soybeans. Rice was first introduced in the 1920s. When the western two-thirds of the state ceased growing crops, the eastern third of the state accounted for 94% of the income from cotton and soybeans and 99% of state's income from rice. The major crops were soybeans, cotton, hay, corn and rice. The state also grew great quantities of peaches, strawberries, tomatoes, watermelons, spinach, pecans, sorghum, wheat and grapes. Arkansas was second in the nation in production of broilers in the late 1950s, the western section of the state being the poultry raising area. Livestock and poultry accounted for about 34% of the total agricultural economy.

Forest Products.—Arkansas is usually among the first ten states in the production of forest products. Approximately 19,350,000 ac. of forest land produce annually about 1,000,000,000 bd.ft. of pine, white oak, gum, red oak, nonpulping hardwoods, ash and hickory. Wood products are valued at more than $300,000,000 annually.

Water Power.—Bull Shoals, Norfork, Narrows and Blakely Mountain dams, all federal projects, produce an average of 600,000,000 kw.hr. a year. In addition they provide flood control and vast recreational areas. The lakes created by these dams attract fishermen and water sport enthusiasts from a wide area and are visited annually by tourists from throughout the nation.

Minerals.—The state has a rich assortment of minerals. Among them are petroleum, natural gas, coal, bauxite, limestone and manganese. By the 1960s, fuels accounted for approximately 69% of the total mineral production; two-thirds of the state's mineral income was derived from the production of petroleum, natural gas and coal. Coal, first mined in 1840, became important economically by the 1870s. Following World War II production declined. Natural gas was first discovered in 1887, but was not drilled commercially until 1901. Production amounted to more than 32,000,000,000 cu.ft. annually in the 1960s. After the discovery of petroleum at Smackover in 1921, oil production boomed reaching 77,000,000 bbl. annually in the peak year of 1925. More than 30 years later, production averaged about 30,000,000 bbl. per year. Probably the most important of the state's minerals is bauxite from which aluminum is made. Arkansas leads the U.S. in the production of this mineral, averaging about 1,500,000 tons annually. Pulaski and Saline counties contain more than 95% of the aluminum ore found in the United States. Manganese, first mined in 1950, barite and bromine are also important minerals economically.

Manufacturing.—Only 2% of the population was engaged in manufacturing in 1900. A half-century later, the figure was only slightly larger (less than 5% in 1950). But in 1958 nonfarm wages and salaries amounted to more than one-half of Arkansas' personal income for the first time in its history. Manufacturing consists mostly of processing raw materials for marketing. Besides lumbering and the production of wood products (see *Forest Products* above), shoe and garment manufacturing, vegetable and fruit canning, petroleum refining, oil extraction from cottonseed, rice milling and the making of clay and glassware products are among the important manufacturing enterprises.

Transportation.—The picturesque river boat was supplanted long ago on the Mississippi by the squat towboat with its tow of barges. Although the Mississippi is navigable along the entire eastern side of the state, and the U.S. corps of engineers maintains a 6.5-ft. channel in the Ouachita as far upstream as Camden, highways and railroads carry most of the traffic. The state highway system at mid-20th century included about 10,000 mi. of highways supplemented by approximately 58,000 mi. of county roads. In 1949 the state began a highway construction and repair program financed by four annual bond issues. Arkansas' share of federal funds, under the national highway program initiated in 1956, amounted to more than $29,500,000 for the fiscal year 1961. There were more than 75 private or municipal airports.

BIBLIOGRAPHY.—*Arkansas and Its People*, vol. i, ii, history, iii, iv, biography (1931), is a local history edited by David Y. Thomas. Perhaps the most readable history is John Gould Fletcher's *Arkansas* (1947). Other works are: Arkansas Industrial Development Commission, *The Arkansas Encyclopedia* (1958); H. M. Alexander, *Government in Arkansas* (1957); O. E. McKnight and B. W. Johnson, *Arkansas Story* (1955); T. S. Staples, *Reconstruction in Arkansas, 1862–74* (1923); D. Y. Thomas, *Arkansas in War and Reconstruction 1861–1874* (1926). The biennial reports of the various state agencies are invaluable for statistical information. *Arkansas' Natural Resources* (1942), ed. by Roy W. Roberts, George C. Branner and Morgan R. Owens, is a complete account of the state's natural resources.

Current statistics on production, employment, industry, etc., may be obtained from the pertinent state departments; the principal figures, together with the current history, are summarized annually in the *Britannica Book of the Year*, American edition. (K. W. P.)

ARKANSAS RIVER. The Arkansas river rises in the Rocky mountains of the western United States near Leadville, Colo., on the Sawatch and Mosquito ranges, 10,000 to 14,000 ft. high. From its source the river flows through mountainous terrain, then over a vast expanse of flat land, emptying into the Mississippi river 40 mi. north of Arkansas City, Ark., 150 ft. above sea level. Its total length is 1,450 mi., and the drainage basin is 157,900 sq.mi. in area.

Great differences in climate, elevation and land forms within the drainage system result in highly variable characteristics of the river.

From Leadville, the river flows southeast through mountainous terrain for 150 mi. leaving the Rocky mountains at Canon City, Colo. In this distance the stream drops 6,700 ft. The river leaves the mountains through the Royal gorge, a narrow canyon cut into solid granite with vertical walls over 1,000 ft. high.

From Canon City to Great Bend, Kan., the river flows east over land that receives less than 20 in. of rainfall annually. The stream channel is wide and meandering with split channels and numerous sandbars. The river flood plain is wide and occasionally covered by floodwater from heavy rainfall upstream. On the stream terraces, land above the flood plain, are irrigated farms. Much of the river water is diverted during the growing season and the river bed contains a mere trickle of water or is dry during the irrigating season. Ten miles east of Las Animas, Colo., just below the confluence of the Purgatoire and Arkansas rivers, is the John Martin reservoir. It is one of the largest water-storage and flood-control units on the river. The reservoir, with a total capacity of 645,700 ac.ft., was completed in 1948.

From Great Bend to the Mississippi river the Arkansas flows over a humid landscape with 20 to 40 in. of annual rainfall. The river is larger than in the upper reaches, frequently over ½ mi. wide, with a deep channel. Because the river is contained in a definite channel by hills on either side, especially in eastern Oklahoma and in Arkansas, the river can do little changing of course. While the river gradient is slight the erosion of the land is intense and the stream is slow and muddy. Red and yellow clays and the fine black loams of the bottom lands provide the characteristic colours of the stream water.

At Little Rock, Ark., the hills that contain the stream dwindle. From here to the Mississippi land conditions are made to order for a vengeful and rambunctious river. Actually the Arkansas flows over a wide section of the Mississippi flood plain. Its stream gradient is shallow and the river becomes a maze of stream meanders, ever-changing patterns of stream channels, abandoned channels, loops and cutoffs. Because the river banks have been built up by heavy deposition of alluvium, the land slopes downward from the river banks and is subject to severe flooding. In these lowland areas swamp conditions prevail over large areas because of extremely poor drainage. During floods old abandoned stream channels become activated and are again used to discharge large volumes of excess water. When the river recedes some of the formerly abandoned stream channels become the main channel of the stream again. Thus the Arkansas presents an ever-changing spectrum of active and abandoned stream beds.

Discharge of the Arkansas river is extremely variable, its water rising and falling constantly at any particular point. The rhythm of the river consists of two periods of high water. One is in winter when rainfall is heavy in the lower part of the river system with but slight discharge in the upper portion where it is frozen.

The second high-water period occurs in late spring and early summer when rainfall is heaviest in Kansas, Oklahoma and Colorado and when the vast quantities of accumulated winter snow begin to melt in the Rocky mountains. Minimum flow periods occur in September and December. At Little Rock the water level varies about 27 ft. between the high- and low-water stages.

Principal tributaries of the Arkansas from source to mouth are the Purgatoire, Cimarron, Verdigris, Neosho and Canadian rivers. The principal cities on the river are Pueblo, Colo., Wichita, Kan., Tulsa, Okla., and Fort Smith and Little Rock, Ark.

ARKLOW (Inbhear Mór), an urban district of County Wicklow, Ire., 43 mi. S. of Dublin by road. Pop. (1961) 5,390. Land area 2.6 sq.mi. Arklow lies at the mouth of the Avoca river and is a seaside resort. There is some fishing, shipping and shipbuilding (the first motor fishing boat of the British Isles was built there), and there is a pottery industry. After the Anglo-Norman invasion, Henry II granted Arklow to the invaders. In 1649 the castle was seized by Oliver Cromwell, and in the rising of 1798 British forces defeated the insurgents after fierce fighting. A tower of the castle still stands.

ARKOSE is a type of coarse sandstone (*q.v.*) presumed to have formed by the disintegration, without appreciable decomposition, of a granite. Arkose consists, therefore, primarily of quartz and feldspar (mainly orthoclase or microcline) together with small amounts of mica (biotite). These minerals, moderately well sorted and generally but slightly worn, are loosely cemented with calcite or less commonly with iron oxide or silica. Arkoses are distinguished from the normal quartzose sandstones (orthoquartzites) by their high feldspar content and from the graywackes by their lighter colour (*see* Graywacke). In the absence of stratification, arkose may bear superficial resemblance to granite, and it has been aptly described as reconstituted granite or granite wash. Like the granites from which they came, arkoses are pink and, less commonly, light gray.

Well-known examples of arkose are the Pre-Cambrian Torridonian of Scotland and the related Sparagmites of Norway, the Portland and New Haven arkoses of the Newark series (Triassic) of the Connecticut valley region, and the Fountain arkose (Pennsylvanian) of Colorado and Wyoming.

The geological significance of arkose has been much debated. Under normal conditions, little feldspar escapes decomposition and conversion to clay, etc., during weathering of the source rocks. Under conditions of rigorous climate (extreme dryness or extremely low temperature) the decomposition of the feldspar is inhibited or greatly retarded. Arkoses were, therefore, presumed to be derived from the erosion of a granitic terrane characterized by an arid or a glacial climate. It is now known, however, that the feldspar may escape destruction, and therefore be transported and deposited with the quartz sands, if the relief of the source region is high enough. Under such conditions, irrespective of the climate, erosion is so rapid, especially in deeply incised canyons, that weathering or decomposition processes are incomplete and the sands derived from such regions are highly feldspathic. Arkoses, therefore, may be said to indicate either a climatic extreme or high relief. Most ancient arkose deposits seem to be the product of high relief.

(F. J. P.)

ARKWRIGHT, SIR RICHARD (1732–1792), English industrialist and inventor of spinning machinery, was born at Preston, Lancashire, on Dec. 23, 1732. He was the youngest of 7 children and was brought up to be a barber and wigmaker. He later traveled about the country buying hair for wigs which he prepared and dyed by a process of his own. He was a man of great enterprise and determination and, having received little education, continued to educate himself until late in life. In 1767 he began to construct his first spinning machine which he patented in 1769, and in partnership with John Smalley, later joined by Jedediah Strutt and Samuel Need, who supplied the necessary capital, started a small factory at Nottingham. He then built a factory at Cromford, Derbyshire, which was run by water power. He also designed and built carding engines and drawing frames which he made to function satisfactorily. Within a few years he had many factories in different parts of the country which were equipped with a sequence of machines for carrying out all the manufacturing operations from carding to spinning. Arkwright's spinning machine made use of L. Paul's drafting rollers and it is doubtful if any of the fundamental ideas in his inventions were his own; in fact, his comprehensive patent of 1775 was rescinded. His technical achievement was rather in embodying the ideas of others in machines that he made to work successfully. Even more important was his organization of large-scale production in factories employing power-driven machinery and division of labour. The thread made on the spinning jenny, invented about 1767 by James Hargreaves, could only be used for weft, since it lacked the strength required in the longitudinal threads or warp. Arkwright's machinery could make cotton yarn suitable for warps and there-

fore was able to fulfill a great potential demand. By 1782 he had a capital of £200,000 and employed 5,000 workers. In spite of losing his patent rights, Arkwright retained his dominant position in the textile industry and at his death at Cromford on Aug. 3, 1792, he left a large fortune. He had been knighted in 1786.

See R. S. Fitton and A. P. Wadsworth, *The Strutts and the Arkwrights 1758–1830* (1959). (K. R. G.)

ARLES, a city of southeastern France, lies in the *département* of Bouches-du-Rhône, 55 mi. N.W. of Marseilles by road. It is in the sandy and salty Camargue plain where the Rhône divides to form its delta. Pop. (1962) 29,251.

The main part of the town lies on the left bank of the Rhône. The old quarter, with its narrow winding streets, is surrounded by Roman and medieval ramparts. In the Place de la République, which has a Roman obelisk in the centre, is the town hall (17th century), containing the library; the art museum, formerly a Gothic church, which has a good collection of Roman remains; and the cathedral of St. Trophime. Founded in the 7th century, St. Trophime was rebuilt several times and has a splendid 12th-century portal and beautiful cloisters. There is also a museum of Provençal arts and crafts founded by the poet Frédéric Mistral. During his stay at Arles in 1888–89 the painter Vincent Van Gogh entered into his great productive period. Among the Roman remains are a large amphitheatre, now sometimes used for bullfights; a theatre, in which the famous Venus of Arles was discovered in 1651; the ruins of the palace of Constantine; the forum; the baths; and a cemetery, the Aliscamps or Alyscamps (*Elysii campi*), consisting of an avenue bordered by trees. The town has modern outskirts and across the Rhône is the suburb of Trinquetaille, badly damaged by bombing in World War II.

Arles is on the main railway line from Paris and Lyons to Marseilles, Nice and Genoa. It is linked with the sea by the Rhône, and by the Arles–Port-de-Bouc canal. Agriculture is the main occupation, especially the cultivation of corn, vines and olive trees and the breeding of sheep. The production of rice, early vegetables and fruit has also been developed. Industry includes the manufacture of metals and chemicals, shipbuilding and paper-making. The port, once little used, is a frequent calling place for oil tankers.

Already important in the days of the Ligurian tribes, Arles was made the Roman colony of Arelate by Julius Caesar in 46 B.C. and from its political, religious and commercial importance it soon became one of the leading cities of the Western Roman empire. Its bishopric was founded by St. Trophimus in the 1st century, and it became the seat of the prefecture of the Gauls (395) and the primatial see (417). A number of synods were held there. The city declined when it passed to the Visigoths and was plundered by the Saracens in 730. In the 10th century it became the capital of the kingdom of Arles and recovered much of its former importance. In the 12th century it became a free city, governed by a podesta and consuls like an Italian republic, which it also resembled in its commerce and navigation. In 1251 it submitted to Charles I of Anjou and from then onward its fortunes were linked with those of Provence. Its bishopric was suppressed in 1790. (J.-M. Ro.)

ARLES, KINGDOM OF (Lat. REGNUM ARELATENSE), the name given from the 13th century onward to the kingdom formed in A.D. 934 by the union of the kingdom of Provence with the kingdom of Burgundy and bequeathed in 1032 to the German king and emperor Conrad II by its last independent ruler, Rudolf III. The composite kingdom, which was known simply as the kingdom of Burgundy up to the end of the 12th century (the name Burgundy thereafter being increasingly reserved for the duchy and for the countship of Burgundy), extended from the upper Saône and from western Switzerland in the north to the Mediterranean in the south and from the Alps and the Valle d'Aosta in the east to the Rhône and across it into Vivarais, Forez and Lyonnais in the west. For the origins of the component kingdoms and their history down to 1032 *see* BURGUNDY; PROVENCE.

Rudolf III had never exercised more than nominal authority over the chief lords of the kingdom, the count of Burgundy (*see* FRANCHE-COMTÉ) and the count of Maurienne (founder of the house of Savoy). The German kings likewise enjoyed little real authority in their new possession. They could generally rely on support from the local bishops during the first 50 years after 1032, but they lost most of this in the course of their quarrel with the papacy. In the 1050s Rudolf of Rheinfelden (the future German king) was sent to Arles to strengthen royal control, probably with the title of "duke and rector of Burgundy," and toward the middle of the 12th century the rectorate was conferred on Conrad of Zähringen, whose family retained hereditary authority over the areas east of the Jura (Burgundia Minor or the Lesser Duchy) until the death of the last Zähringer duke in 1218. The emperor Frederick I's marriage with Beatrix, daughter of the count of Burgundy, in 1156, gave him more real power over the kingdom, but Henry VI was ready to invest Richard I of England with it in 1193. Frederick II, who had to take strong measures to assert his authority over that of his vassal Raymond Berengar V (IV) of Provence, tried to make his power more effective by delegating it first to a viceroy, then to a series of imperial vicars.

Imperial influence, however, gradually gave way to French. Louis VIII of France had intervened in Provence in the course of the crusade against the Albigenses, and Louis IX had married Raymond Berengar's eldest daughter Margaret. In 1246 Raymond Berengar's heiress Beatrix was married to Louis IX's brother Charles, count of Anjou (the future Charles I of Naples), so that the whole countship of Provence passed to the Angevin dynasty. By a treaty of 1295 the countship of Burgundy or Franche-Comté passed to the future Philip V of France. Vivarais and Lyonnais acknowledged French suzerainty early in the 14th century and Dauphiné was sold in 1349 to the future Charles V of France by Humbert II, dauphin of Viennois, who already in 1343 had agreed that on his death it should pass to a descendant of Philip VI.

Finally, in 1378, the emperor Charles IV, though he had taken some part in the affairs of the kingdom and in 1365 had been crowned at Arles, ceded the imperial vicariate to the dauphin Charles, later Charles VI of France. As the northeastern and eastern territories of the old kingdom were by this time in the hands of the counts of Savoy, the cession of 1378 marks the end of the kingdom of Arles.

Halphen, "The Kingdom of Burgundy," in *Cambridge Medieval History*, vol. iii (1936).

ARLES, SYNOD OF, the first representative meeting of Christian bishops in the Western Roman empire, was convened (Aug. 314) by the emperor Constantine in order to decide such questions as the date of Easter, the problem of Donatism and the validity of baptisms by heretics and of ordinations by traditores, those who had surrendered the sacred books during the persecution under Diocletian. This synod, attended by representatives of 43 bishoprics, was held because Donatists (*q.v.*) had denied the representative character of two earlier synods, at Rome and in Africa, at which their leader Donatus had been condemned. They continued to reject synodical decisions and appealed to the emperor against those made at Arles; they also instituted civil suits against various traditores, sometimes using forged documents. The church, however, regarded the decisions of Arles as binding. *See* AUGUSTINE, SAINT: *Donatist Schism.*

See W. H. C. Frend, *The Donatist Church* (1952); S. L. Greenslade, *Schism in the Early Church* (1953). (R. McQ. G.)

ARLINGTON, HENRY BENNET, EARL OF (1618–1685), English statesman, was a prominent member of Charles II's cabal (*q.v.*). He was born at Saxham, in Suffolk, in 1618 and was educated at Westminster school and Christ Church, Oxford. During the English Civil War he served briefly in the royalist forces, earning the honourable facial scar which is so distinctive a feature of his portraits. He went into exile and from 1657 was an agent in Spain for the future Charles II of England.

Returning to England in 1661 he became a member of parliament for Callington in Cornwall and keeper of the privy purse, but the career during which he was to dominate British domestic and

foreign policy properly began in Oct. 1662 with his appointment as principal secretary of state. In this office he was responsible for relations with France, Spain, the Netherlands, Portugal and Italy, as well as for the intelligence and postal services, and he was able to acquire an influence equal to that of the lord chancellor, the earl of Clarendon. He was created Baron Arlington in 1665. In 1667, by fostering Clarendon's dismissal and impeachment, he helped divert from himself parliamentary dissatisfaction with the management of the second Dutch War; but he now stood exposed to the jealousy of the ambitious cavaliers surrounding George Villiers, 2nd duke of Buckingham. The personal rivalry between Arlington and Buckingham bedeviled politics for the next ten years. Arlington, with greater resources than Buckingham, proved more successful as both a patron and a diplomat. Through him Sir Thomas Clifford, Sir John Trevor and Sir Thomas Littleton reached high office and he sponsored Sir William Temple's negotiation of the triple alliance of England, the Netherlands and Sweden in 1668. At this point Arlington's pro-Dutch policy was attributed to his marriage (1666) to Isabella van Beverwaert, daughter of Louis of Nassau. By 1669, however, he had been drawn into the secret policy of alliance with France culminating in the treaty of Dover (May 1670). He and Clifford were closer in Charles II's confidence than any other members of the cabal, and abetted the king in other aspects of his policy, including the "stop of the exchequer," the Declaration of Indulgence and the open league with France. Arlington was rewarded in 1672 with an earldom and the Garter.

His eclipse began the same year with the appointment of Clifford to the coveted lord treasurership; he was denounced to parliament by Buckingham and was impeached in Jan. 1674 for popery, corruption and betrayal of trust. He defended himself ably and the charges failed, but he shortly resigned his secretaryship for the less exposed role of lord chamberlain. In the years of the earl of Danby's ascendancy Arlington lost all influence. He attempted to regain power by associating with the earl of Shaftesbury's opposition "Country party," but instead Charles II withdrew his confidence. Arlington survived to hold office for a few months under James II, but died, after a deathbed confession of Roman Catholicism, on July 28, 1685.

Arlington's administrative abilities are open to question; he was fortunate in possessing a very able undersecretary in Joseph Williamson, who succeeded him; but he undoubtedly exhibited the full potentialities of the secretaryship of state as a source of power. His control of official correspondence, which he assiduously extended, greatly added to his personal security and his financial stake in the post office proved most profitable. But, as the failures of the second Dutch War showed, the secretary's intelligence service was inferior to Cromwell's, and Arlington was lucky to escape parliamentary censure in 1667. Subsequently he was active in creating the nucleus of a disciplined "Court party" in the house of commons, but the real basis of his influence was the uninterrupted possession of Charles II's confidence. He was prepared to pander to Charles, and at his great country house at Euston in Suffolk, Arlington procured for him the favours of Louise de Kéroualle. However, suppleness of this sort conflicted with a certain stiffness of manner which made him the butt of court wits; this was generally attributed to his admiration for things Spanish and jarred with the predominantly French tone of the English court. Arlington was also handicapped by a series of quarrels with James, duke of York, and it seems likely that his loss of favour was due to an early belief that the exile or even exclusion of James was desirable.

Arlington's only "expensive vice" was a passion for building, indulged at Euston and at Goring house, now the site of Buckingham palace. His religious beliefs were carefully dissimulated and rumours of his Catholicism fell into abeyance until his death.

Feiling, *History of the Tory Party 1640–1714* (1924) and *British Foreign Policy 1660–1672* (1930); A. Browning, *Thomas Osborne, Earl of Danby and Duke of Leeds*, 3 vol. (1944–51). (H. G. Ro.)

ARLINGTON, a city of Tarrant county, Tex., U.S., in the "Golden Triangle" (Arlington, Grand Prairie and Irving), characterized by rapid growth and careful modern planning, 18 mi. W. of Dallas and 12 mi. E. of Fort Worth. The first settlement, Bird's Fort (about 1845), was on an Indian council site; there Sam Houston counseled Comanches. Johnson's Station, the first Tarrant county plantation, preceded Arlington, named for Robert E. Lee's ancestral mansion and incorporated in 1920.

The city's population increased by almost sixfold from 1950 to 1960. For comparative population figures *see* table in Texas: *Population.*

A beautiful, tree-lined city, Arlington is the home of Arlington State college. A private academy was founded on the grounds in 1894; the school, which has undergone several changes of name became state-supported in 1917 and assumed senior college status in Sept. 1959.

Primarily an industrial and commercial centre, Arlington has as its most important industries automotive, aviation and missiles. (E. C. Be.)

ARLINGTON HEIGHTS, a city of Cook county, Ill., U.S., situated on high ground 22 mi. N.W. of downtown Chicago. On its west boundary is the Arlington park race track (opened in 1929). The first settlers came in 1833, even before the treaty was ratified with the Potawatomi Indians (1836). The town was originally called Dunton in honour of Asa Dunton, an early settler. After the Civil War as a patriotic gesture, the name was changed to Arlington Heights (1874).

The three largest factories, established in the early 1900s, make school furniture, felt erasers, bulletin boards, fabricated chalk boards and metal milk containers. Most of the employed residents commute to Chicago to work. The city was incorporated in 1887, and has been governed by a council-manager form of government since 1954.

For comparative population figures *see* table in Illinois: *Population.* (H. L. Sm.)

ARLINGTON NATIONAL CEMETERY occupies a beautiful site of more than 400 ac. in Virginia on the banks of the Potomac river, directly opposite Washington, D.C. The central feature of the cemetery is the mansion, built in 1802 of stuccoed brick on the estate of George Washington Parke Custis the adopted son of George Washington. The Custis-Lee mansion as it is now called, is said to have been modeled after the temple of Theseus in Athens. The portico, with its eight white columns is a striking landmark visible from the city across the river. Many famous Americans and foreigners, among them La Fayette have been entertained at the mansion. In the family parlour Mary Anna Randolph Custis in 1831 married Robert E. Lee, then a lieutenant in the United States army, afterward commander in chief of the Confederate army.

When, on April 22, 1861, Lee left Arlington to command the Virginia troops, federal soldiers took possession almost immediately, converting the mansion into a headquarters and the grounds into a camp. In 1864 Arlington became a military cemetery by order of the secretary of war. An area of 210 ac. was first set aside for this purpose and later the area was doubled. For years the title of the property was in dispute, but in 1883, after a supreme court decision favourable to George Washington Custis Lee, the United States government, by payment of $150,000 to him, obtained a clear title. The first soldier was buried in the cemetery on May 13, 1864; some of the dead from every war in which the United States has participated, including a few officers of the American Revolution, have since been buried there.

The cemetery, with its beautiful rolling terrain, its 20,000 trees and ten miles of winding paved roads, is a truly lovely spot. It is the resting place of many of the nation's great military leaders and outstanding individuals from various walks of life, including William Howard Taft, John F. Kennedy, Adm. Robert E. Peary, Gen. John J. Pershing, Adm. Richard E. Byrd, Gen. Jonathan M. Wainwright, Gen. George C. Marshall and Maj. Pierre Charles l'Enfant, the French engineer who designed the city of Washington. Any member of the armed forces of the United States who dies in active service and any former member whose last active service terminated honourably may be buried in Arlington.

The best-known memorial in the cemetery is the Tomb of the Unknowns, originally a memorial to the United States unidentified

dead of World War I. Formerly known as the Tomb of the Unknown Soldier, the shrine was renamed on Memorial day 1958, when unidentified servicemen of World War II and the Korean war were interred beside the solid block of marble; the inscription, "Here Rests in Honored Glory an American Soldier Known But to God," thereafter was considered to refer to all three crypts. A continuous guard is maintained at the tomb by selected soldiers of the 3rd "Old Guard" infantry regiment, United States army, Ft. Myer, Va. Sentinels relieve one another during a simple guard-changing ceremony every hour on the hour.

Near at hand stands the memorial amphitheatre erected through the efforts of the Grand Army of the Republic in memory of departed heroes, as a fitting place of assembly for the thousands who attend Memorial day services in their honour. It was dedicated on May 15, 1920. The roofless, white marble structure, with its eastern façade overlooking the Potomac river and Washington, encloses a natural amphitheatre. Copied after both the theatre of Dionysus at Athens and the Roman theatre at Orange, France, the proportions and distances convey the charm of an old Greek ruin. Crypts where especially distinguished servicemen may be buried are placed under the colonnade, while within the entrance are a reception hall, a chapel and a museum. The eyes of visitors—who may enter Arlington daily between sunrise and sunset—turn repeatedly to the Fields of Dead, with their seemingly endless lines of plain stones, of the pattern adopted in 1872 for use in all national cemeteries.

See "Arlington National Cemetery," Office of Arlington National Cemetery, U.S. Army (1961); *The Unknowns of World War II and Korea*, U.S. Government Printing Office, Washington, D.C. (1959).
(K. E. Bd.)

ARLISS, GEORGE (1868–1946), British film and stage actor, was born in London on April 10, 1868. He worked in his father's printing and publishing office until 1887, when he began his acting career. He met with his first substantial success appearing with Mrs. Patrick Campbell in London (1900–01). In 1902 he played in New York city in *The Second Mrs. Tanqueray.*

Arliss was already established as a leading actor when he turned to films in 1920. During his film career he usually portrayed famous historical characters, his pictures including *The Green Goddess* (1930), *Old English* (1930), *Alexander Hamilton* (1931), *The House of Rothschild* (1934) and *Cardinal Richelieu* (1935). The Academy of Motion Picture Arts and Sciences voted him the best actor of 1929–30 for his role in *Disraeli.* Arliss wrote two autobiographical works: *Up the Years From Bloomsbury* (1927) and *My Ten Years in the Studios* (1940). He died in London, Feb. 5, 1946.

ARMADA. The Spanish Armada (Sp. *Armada Invencible*) was the great fleet sent in 1588 by Philip II of Spain, leader of Catholic Europe, to assist in the attempted invasion of England. He had long been trying, by every means short of open war but if necessary by assassination, to overthrow Elizabeth I of England, the champion of Protestantism. She was aiding the Netherlanders in their rebellion against his regent, Alessandro Farnese (*q.v.*), duke of Parma, and her seamen were threatening his essential communications across the Atlantic. Elizabeth, although anxious to avoid war, knew that her life and England's national integrity and religious and economic future depended upon opposing him successfully. It was the devastating descent upon the Spanish colonies in America (1585–86) by Sir Francis Drake (*q.v.*) that finally convinced Philip that direct invasion was his only remedy. He thought first of launching it directly from Spain, but his trusted admiral, the marqués de Santa Cruz (*q.v.*), produced so staggering an estimate of the cost (suggesting 556 ships carrying 94,000 men) that Philip decided to use Parma's veteran army as the striking force and to send from Spain only sufficient strength to beat the English fleet and clear the straits of Dover for his army to cross.

Preparations were seriously delayed in 1587 by Drake's surprise attack on Cádiz. This did more than "singe his Catholic majesty's beard": it taught Philip that his oar-propelled galleys, still the backbone of Spain's fighting fleet, were no match for Elizabeth's new, swift-sailing navy. So he sent instead about 24 warships and the best merchantmen he could find, hastily converted for war. Thus the Armada was not Spain's conventional fighting fleet. Philip also learned from this raid the value of artillery in sea warfare. Drake's guns, mounted on the broadside, had played havoc with galleys whose guns could not be so mounted. Philip had no intention of forsaking the traditional Spanish tactics of "boarding and entering," but he saw that to get his ships alongside the far more mobile English vessels he must provide considerable batteries of the heavy guns then known as "cannons" and "periers" whose round shot, weighing up to 50 lb., could halt any ship. Elizabeth's fleet was radically different. Her seamen had evolved an entirely new form of warfare based upon the increased speed and maneuverability of their ships, combined with the use of broadside fire from many long-ranged, although light shotted, guns known as "culverins." Indeed, they had actually discarded their galleys altogether and almost all their heavy but short-ranged cannons. Thus equipped, they proposed always to attack their lumbering enemy from to windward, carefully keeping outside the effective range of his 50-pounders: so confident were they in their new technique that they had virtually discarded their soldiers. These basic differences of aim between the English and the Spanish were clearly reflected in the numbers of men and in the armament eventually employed.

Country	Ships		Men		Guns (4-pounders and over)			
	Total	Front line	Soldiers	Sailors	Total	% heavy short-range	% light long-range	Average weight of shot
Spain	130	68	19,000	8,000	1,124	44	56	17 lb.
England	197	61	1,500	14,500	1,972	5	95	7½ lb.

Santa Cruz died on Feb. 9, 1588, and the Armada was commanded by the duque de Medina Sidonia (*q.v.*); highborn, amiable and conscientious, the duque was ignorant of the sea, reluctant to serve and no leader of men. The English were more fortunate in their lord admiral, Charles Howard of Effingham (*see* Nottingham, Charles Howard, 1st Earl of); he was, like Medina

ROUTE OF THE SPANISH ARMADA, JULY 29 TO AUG. 9, 1588. BATTLES BETWEEN SPANISH AND ENGLISH FLEETS INDICATED BY X. (*See* TEXT)

PAINTING OF THE FIRESHIP ATTACK ON THE SPANISH ARMADA OFF THE COAST OF CALAIS, FRANCE, AUG. 7–8, 1588; ARTIST UNKNOWN. IN THE NATIONAL MARITIME MUSEUM, GREENWICH, ENG.

Sidonia, a nobleman and no seaman, but, unlike him, a born leader. The Armada cleared the Tagus estuary in the Iberian peninsula on May 28 (new style; May 18, old style) but because of storms, sickness and the necessity of replacing rotten stores, it did not leave until July 22, sighting the Lizard peninsula, Cornwall, Eng., on the 29th. The English meanwhile failed to profit from the delay. Drake wanted to make a bold sortie, attacking the enemy on his own coast, but Elizabeth, still loath to precipitate war, would not consent. Yet Drake did succeed in getting the main fleet moved to Plymouth whence it could hope to take advantage of the prevalent westerly winds. The fleet was then nearly caught in enclosed waters where it could not use its mobility but where Medina Sidonia could use his army. It was saved only by Philip's strict and unimaginative orders for the Armada to proceed upchannel in a tight defensive formation, refusing battle until junction was made with Parma, and by the brilliant seamanship of the English captains who, scenting danger, contrived to warp out of Plymouth harbour on a contrary wind and, crossing the bows of the Armada, worked westward to regain the all-important wind. Medina Sidonia's best chance was gone.

The English then attacked, but only at open range, according to plan. Three actions followed, off Plymouth (July 31), off Portland (Aug. 2) and off the Isle of Wight (Aug. 4). All were tactically indecisive although off the Isle of Wight the English scored a great strategic success by forcing Medina Sidonia past the last anchorage in which he could mark time if Parma were not ready. The English were able so completely to dictate conditions and to avoid close action that they suffered practically no damage; yet the results disappointed them for they failed to break Medina Sidonia's defensive formation. In fact a major flaw in the English tactical planning was gradually revealed: although their round shot could and did hit the enemy at a range where his could hardly reach them, it did not penetrate the hulls. The English could at this point annoy and delay the Armada, but not break and, still less, destroy it.

Medina Sidonia reached the straits of Dover on Aug. 6 and anchored off Calais, France, his stubborn formation still intact. The English also anchored, still to windward. Medina Sidonia found the French governor friendly—but Parma apparently was not ready. The regent's position was indeed impossible; he could not put to sea from his ports of Dunkerque and Nieuwpoort, having no fighting escort for his landing craft. Moreover he was doubly blockaded, by Lord Henry Seymour's English squadron in The Downs (English channel roadstead off Deal, Kent) and by the large if ragged flotilla of the Sea Beggars (Dutch privateers) at Flushing, Neth. In plain fact, Philip's whole conception of a junction off Flanders was a monstrous strategic blunder, based upon the fallacies that accurate co-ordination between the land and sea forces could be achieved and that England could be militarily invaded by a power that had not first obtained absolute mastery of the English channel.

Medina Sidonia too was in difficulties. Since wind and enemy prevented retreat westward, he could only sail northward—away from Parma altogether—or eastward to suicide on the Zealand banks. The English naturally exploited his embarrassment. At midnight on Aug. 7–8 they launched six fire ships straight downwind. All missed their targets yet entirely fulfilled their purpose, because the Spaniards in panic cut their cables and drifted eastward, their formation irretrievably lost. The English ships drove headlong into the Spanish fleet and the decisive battle off the coast of Gravelines, France (Aug. 8), ensued: and it differed profoundly from the earlier encounters. For soon the Spanish heavy guns fell silent, their round shot spent. The English, perceiving this, closed to a point-blank range at which their light weapons began to justify themselves. That day the Armada received its first and only real hammering. Three ships were certainly destroyed, perhaps several more, while the survivors and especially the flagships were battered into impotence, some dismasted and others leaking dangerously. All became prey to black despair, since throughout the engagement the fleet was drifting steadily to what seemed certain shipwreck.

But fate relented. First, the English also ran out of ammunition and were reduced to a game of bluff; second, when all seemed lost the wind suddenly shifted from northwest to southwest, allowing the Armada to claw off the lee shore and steer north into deep water. The fighting was over but not the tragedy. The Armada held on northward, committed now to navigating the long, dangerous route via Cape Wrath at the northwest extremity of Scotland and the open Atlantic. The English fleet followed until Aug. 12, and then returned home. The Spaniards lacked every necessity for their homeward journey—masts, sails, food, water and even, after their hasty departure from Calais, anchors. Typhus raged among the crews, shot-racked timbers crumbled, seams opened and many ships foundered or were wrecked on the Irish coasts. Some 51 ships did not reach home, and many thousands died of disease and sheer exhaustion even after disembarkation from those vessels that did reach Spain. The English naturally fared better. They lost no ships and, in battle, not 100 men. But before demobilization could begin, a virulent form of food poisoning killed perhaps 30 times as many as the Spaniards had slain.

On every count the Armada's defeat was epoch-making. It probably saved the Reformation and it certainly saved England; and it taught England that the sea would be the instrument of its future greatness. It was also of great significance in the history of war as the first gun duel between fleets propelled exclusively by sail, the prototype of all naval actions up to and including the battle of Trafalgar (1805).

ARMADILLO, a mammal (order Edentata, family Dasypodidae) closely related to the sloths and anteaters and possessing a heavy coat of armour composed partly of solid bucklerlike plates and partly of movable transverse bands. Armadillos are omniv-

orous, feeding on termites, other insects, roots, worms, reptiles and carrion, and are mostly nocturnal. They are harmless, inoffensive creatures, their principal means of escape being the rapidity with which they burrow into the ground and the tenacity with which they retain their hold in their subterranean retreats and dwelling places. Armadillos also avoid danger by fleeing; they can run rapidly although their legs are short. Their flesh is sometimes used by natives as food. They are all inhabitants of the tropical and temperate parts of South America, although a few species range farther north, the peba or nine-banded armadillo (so called because of the bands around its middle) being found from Argentina to northern Texas. The adult male of this species is about 32 in. long and weighs about 13 lb.; the female is slightly smaller. The largest species is the giant armadillo (*Priodontes*), nearly five feet long including tail, found in Surinam and Brazil. For the distinctive characters of the genera *see* EDENTATA: *Armoured Edentates.*

NINE-BANDED ARMADILLO (DASYPUS NOVEMCINCTUS)

ARMAGEDDON, mentioned in the Bible only in Rev. xvi, 16, the place where at the end of world history the kings of the earth under demonic leadership battle the forces of God (Rev. xix, 11–21). The name, said to be Hebrew, probably represents two Hebrew words, *har megiddo*, "mountain (or hill) of Megiddo." The Palestinian city Megiddo was located where a strategic pass cut through the southeastern extension of the Mt. Carmel ridge from the coastal Plain of Sharon into the Plain of Esdraelon; Megiddo thus commanded the direct road from Egypt and the Palestinian coastal plain to Galilee, Syria and Mesopotamia. During its history, from the 4th millennium B.C. to the 4th century B.C., it was the scene of many important battles (as, indeed, it was also during World War I), and Rev. xvi, 16 seems to imply that the "hill" on which the city fortress stood, or the "mountain" heights behind it, had become a symbol of the final battlefield where God's heavenly armies will defeat the demon-led forces of evil. *See* also MEGIDDO. (F. V. F.)

ARMAGH, an inland county of Northern Ireland, is bounded on the north by Lough Neagh, northwest by Tyrone, east by County Down and south and west by the frontier of the Republic of Ireland. Its area is 512 sq mi.

Physical Features.—The low-lying northern area is made up of Tertiary basalts, Pliocene deposits and Triassic and Old Red Sandstone. It is very fertile and may formerly have been covered by the water of Lough Neagh. To the south there is a gradual rise to the mountains of Ordovician and Silurian rocks, which reproduce the trend and pattern of similar formations in the southern uplands of Scotland. Farther south the granite mountain core is revealed, while younger intrusive igneous rocks form Slieve Gullion (1,894 ft.). The Ice Age gave to the scenery of northern and central Armagh much of its distinctive character. There are vast numbers of drumlins, or small low hills, which give rise to picturesque scenery on a small scale, and the glaciers were also responsible for many lakes and ponds. Glacial debris formed the long spur running south from Slieve Gullion.

History.—In late prehistoric times and at the dawn of history Armagh was an important populated area in Ulster. About the beginning of the Christian era the fortress of Emain Macha, 2 mi. W. of the modern Armagh town at the site known as Navan fort, was the centre of a kingdom of Ulster which extended, at the greatest, as far west as the Shannon and as far south as the Boyne. Also associated with this period is an ancient earthwork, called either the "Black Pig's Dyke" or the "Dane's Cast," running north-east and southwest through several townlands.

A considerable mythology surrounds this early kingdom. The king was Conor MacNessa (Conchobar macNessa), whose many relatives and allies formed a sort of military order called the Red Branch. The greatest was the hero Cú Chulainn, whose father was said to be the sun-god Lugh (Lug). He took part in the fierce wars between the men of Ulster and the warriors of other parts of Ireland, particularly the invading hosts of Maev, queen of Connaught. To Armagh also belongs the tragic story of Deirdre (*q.v.*).

With the decline of this early kingdom of Ulster in the 4th century, Emain Macha lost its importance and Ard Macha, the modern Armagh town, became the political centre of that countryside. It gained added importance after St. Patrick made it his metropolitan see in the 5th century. The Protestant cathedral of Armagh, dating from the 13th century, was restored in the 18th and 19th centuries. Other ancient and ecclesiastical remains are in the vicinity, while at Tynan, west of Armagh, there is a fine Celtic standing cross. The area was ravaged by Scandinavian invaders but they made no permanent settlements. Armagh was a debatable land in many medieval conflicts and lay beyond the "gap in the north" through which representatives of the English crown tried to penetrate Ulster from Dundalk.

The county was made shire ground in 1586 and was included in the scheme for the plantation of Ulster in the early 17th century, being colonized mainly by landowners from England. The gateway of Charlemont fort survives from the vicissitudes of the 17th century. Armagh contains many ancient monuments and buildings of interest, often illustrating the prosperous times enjoyed by the clergy and gentry in the 18th century. This is particularly true of the town of Armagh. Among fine Georgian houses in the county is Derrymore house, 15 mi. S.E. of Armagh, a National trust property.

Population and Administration.—The population of County Armagh was 117,594 in 1961, the largest towns being the municipal boroughs of Portadown (*q.v.*; 18,609) and Lurgan (*q.v.*; 17,872) and the urban district and county town of Armagh (*q.v.*; 10,062). Of the total population, 46% were Roman Catholics, 30% Church of Ireland and 15% Presbyterians. The county returns four members to the parliament of Northern Ireland and one member to the United Kingdom parliament.

Industries and Communications.—The lowland parts of the county form rich agricultural land. West of Portadown, in the district surrounding the villages of Richhill, Kilmore and Loughgall, is Ulster's principal fruitgrowing area, a district that attracts many visitors at blossomtime. The county's many beauty spots draw tourist traffic. Coney Island, a picturesque islet in Lough Neagh, is the property of the National trust, as is the beautiful glen at Ballymoyer, 8 mi. W. of Newry. There is fishing in the rivers Bann, Callan and Cusher and elsewhere.

Although Armagh is mainly a rural county devoted to agriculture, many of the towns are industrialized. At Portadown linen manufacture is carried on; lace, pottery, metal cans and boxes, electrical equipment and synthetic fabrics are made; fruit is packed, fruit and vegetables canned, bacon cured and meat products processed. At Lurgan knitwear, handkerchiefs, optical goods, linen and rayon products, clothing, printed fabrics, chairs and light engineering products are made. At Armagh town clothing, knitwear, cotton and worsted yarn are produced, and the spinning and weaving of linen carried on, while milk products are manufactured in the neighbourhood. Carpets are made at Keady, air-conditioning machinery at Laurelvale, potato crisps at Tanderagee, milk products at Tullygoonigan and electrical goods at Bessbrook. Granite is quarried in the southern part of the county.

Armagh contains a considerable mileage of main railway line and has good road services. The town of Newry (*q.v.*) in adjacent County Down serves to some extent as the port of County Armagh. (HU. S.)

ARMAGH, an urban district and the county town of County Armagh, N.Ire., 36 mi. S.W of Belfast. Pop. (1961) 10,062. At Navan fort, 2 mi. W. of Armagh, is the site of the ancient Emain Macha, military centre of a kingdom of Ulster flourishing about the beginning of the Christian era. (*See* ARMAGH [county].) After the decay and downfall of Emain Macha in the 4th century some of its importance passed to the neighbouring fortified hill of Ard Macha around which the modern town of Armagh rose. In the 5th century St. Patrick made Armagh the ecclesiastical metropolis of Ireland. It is the seat of both the Protestant and Roman Catholic archbishops and has two cathedrals. After much

obscurity during the middle ages, Armagh was modernized and given a number of public institutions. A Royal school was founded in 1627; Archbishop Richard Robinson, who came to Armagh in 1765, founded a library and an observatory; there is now also a county museum. As well as being an important market town and a road and rail junction, Armagh has a number of industries, including the spinning and weaving of linen and the manufacture of clothing and cotton yarn. (Hu. S.)

ARMAGNAC, an ancient province of France, originally a fief of the duchy of Gascony, is now wholly comprised in the *département* of Gers (*q.v.*). It is a region of hills ranging to a height of 1,000 ft., watered by the Gers river and other rivers which descend fanwise from the plateau of Lannemezan. On the slope of its hills grow the grapes from which the famous Armagnac brandy is made.

Toward the middle of the 10th century the countship of Armagnac, around the small town of Nogaro, was one of the feudal units that originated in the decomposition of the diocese of Auch (the former *civitas Ausciorum*). This territory, enlarged during the 12th century by acquisition of the countship of Fezensac, became strategically important as the frontier zone between the kings of England and France, who controlled the duchy of Aquitaine and the countship of Toulouse respectively and whose growing differences enabled the counts to obtain favours from either side.

In 1304 the count of Armagnac's marriage to the heiress of the counts of Rodez established him as a leading power in southwestern France. The Valois kings sometimes appointed him their lieutenant in Languedoc; and two marriages with the Berry branch of the royal family strengthened the links of his dynasty to the monarchy. The treaty of Calais (1360) yielded the sovereignty over the countship of Armagnac to the king of England; but the appeal of the count, Jean I, to Charles V of France (1368) gave the latter his pretext for breaking the treaty and launching his victorious campaigns (*see* Hundred Years' War).

The lesser nobles of the region soon became dependent on the patronage of the counts of Armagnac, whose growing influence was counteracted only by that of the counts of Foix. A series of marriages, successions and purchases made the counts of Armagnac masters of two groups of estates by the beginning of the 15th century: (1) between the Garonne, the Adour and the Pyrenees, the counties of Armagnac, Fezensac and Pardiac, the viscounties of Fezensaguet and Lomagne and the seigniories of Rivière Basse and of the Quatre Vallées (Aure, Magnoac, Labarthe de Neste and Barousse); and (2) on the uplands of the Massif Central, the county of Rodez and the viscounties of Carlat and Murat—together with minor seigniories.

This strong regional position and the services of his rapacious Gascon mercenaries enabled Bernard VII of Armagnac to play an essential part in the great national crisis that opened when John the Fearless, duke of Burgundy, murdered Louis, duc d'Orléans, brother of the mad king Charles VI (1407). The son of the victim, Charles, married Bonne, daughter of Bernard VII, who became a leading member of the feudal coalition against the murderer; thus were formed the "parties" of the Armagnacs and of the Bourguignons. The Armagnac party controlled the king from 1413 and so assumed the direction of resistance against the English, who in 1415 reopened the war against the Valois. The battle of Agincourt (*q.v.*) was a great reverse for the Armagnac party, and many of its leaders were killed.

Bernard VII, however, became more and more powerful; he was made the "governor of all the finances" and chief of the army, with the title of constable and the right to appoint the captains of all the fortresses of the realm. But his government lacked money, and the excesses of his party incensed the population of the major towns; the Bourguignons mastered the situation in Toulouse on May 26, 1418, and in Paris two days later. Bernard VII and his principal adherents were killed.

After 1418 the power of the Armagnacs rapidly decreased. The treaty of Arras (1435) marked the reconciliation of Charles VII of France, who had at first appeared as the king of the Armagnacs, to the duke of Burgundy. Troops of "Armagnacs" (*i.e.,* Gascon mercenaries) were still used by the king and even sent to Alsace and Switzerland (1439–45). The counts gradually lost their regional position. In 1473 a royal army captured their capital of Lectoure, and Count Jean V was killed. On the death of his brother Charles in 1497, the countship was united to the crown of France by Charles VIII. Francis I of France, however, bestowed it upon another Charles (nephew of the last count) and at the same time gave him his sister Margaret in marriage. After the death of her husband, by whom she had no children, Margaret married Henry II of Navarre; and thus the countship of Armagnac came back to the French crown along with the other dominions of their grandson who became king of France as Henry IV. In 1645 Louis XIV erected a countship of Armagnac in favour of Henri de Lorraine, comte d'Harcourt, in whose family it continued until the Revolution.

In the last years of the *ancien régime* Armagnac was a province forming part of the *gouvernement-général* of Guienne and Gascony. It was divided into two parts: High or White Armagnac, with Auch for its capital; and Low or Black Armagnac.

Morel, "Jean de Labarthe et la maison d'Armagnac, un épisode de la concentration féodale au XIVe siècle," *Annales du Midi* (1949).

ARMATOLES (Gr. *armatoloi*), the name given to Greeks discharging certain military and police duties under the Turkish government in districts known as *armatoliks*. This police organization had its origins in Byzantine times, *armatolismos* being a form of feudalism, under which military and police duties were rendered in return for a title to land. When the Turks conquered Greece in the 15th century, they made treaties with the armatoles, allowing them to continue in their police functions. Other Greeks, taking to the mountains, became unofficial, self-appointed armatoles and were known as klephts (Gr. *kleptes*, "brigand"). These klephts might sometimes be recognized by the Turkish authorities as armatoles, while the armatoles who were out of favour continued as klephts. The two terms came to be used indiscriminately. The chief klepht, like the armatoles, was known as *kapetanos*, and the troops were called *palikaria* (palikars). Both armatoles and klephts played a most important part in the War of Greek Independence. (D. Dn.)

ARMATURE. In magnetism William Gilbert applied the term to the piece of soft iron with which he "armed" or capped the loadstone in order to increase its power. It is also used for the "keeper" or piece of iron placed across the poles of a horseshoe magnet to complete the magnetic circuit and preserve the magnetism of the steel; and hence, in dynamoelectric machinery, for the portion that is attracted by the electromagnet. The term is now applied to that member of an electric generator or motor in which currents are induced by the action of the field.

In sculpturing, the armature is the framework of the lead wire or pipe that supports the modeling.

See also Motor, Electric; Sculpture Techniques: *Modeling and Casting*.

ARMAVIR, a town in Krasnodar *krai* of the Russian Soviet Federated Socialist Republic, U.S.S.R., lies on the left bank of the Kuban about 100 mi. E. of Krasnodar. Pop. (1959) 110,994. Founded in 1848, Armavir became a town in 1915. It is on the railway from Rostov-on-Don to Baku, with a line to Tuapse on the Black sea. Good communications and the rich agricultural vicinity led to the development of food-processing industries, including a meat-packing combine (one of the largest in the U.S.S.R.), fruit and vegetable canning, milk processing and buttermaking. Spares for agricultural machinery, equipment for petroleum and transport undertakings, boots and shoes, cord and cotton wool are also produced. Natural gas is obtained nearby. (R. A. F.)

ARMED NEUTRALITY: *see* Neutrality.

ARMENIA (Armenian Hayastan, Turkish Ermenistan, Russian Armeniya), a region and ancient kingdom in southwest Asia. Its historical boundaries have varied considerably, but as a region Armenia is usually regarded as comprising the northeastern part of Turkey and the Armenian Soviet Socialist Republic (Armyanskaya Sovetskaya Sotsialisticheskaya Respublika). The latter is the smallest of the three soviet socialist republics to

Transcaucasia (Georgian, Azerbaijan, Armenian) in the extreme southern part of European U.S.S.R., lying beyond the Greater Caucasus mountain range (Bolshoi Kavkaz). The Armenian S.S.R. covers 11,506 sq.mi. and in Jan. 1959 had 1,763,048 inhabitants. The republic is somewhat cut off from the rest of Transcaucasia and from the European U.S.S.R., but occupies an area of great strategic importance on the Soviet-Turkish boundary.

Turkish Armenia, with an area of about 57,000 sq.mi., unlike Soviet Armenia, has no political designation. It is the location of Mt. Ararat (*q.v.*), the highest point in the region, and the historic Tigris, Euphrates and Aras (Araks, Araxes) rivers have their sources there.

HISTORY

The Armenians make their first appearance in history shortly after the collapse of the ancient kingdom of Urartu (*q.v.*), toward the end of the 7th century B.C. Driving some of the ancient population to take refuge in the lands to the east of Mt. Ararat—where, known to Herodotus as the Alarodioi, they continued for some time to lead a separate existence—the Indo-European invaders imposed their leadership upon those who remained. The occupied regions, although they had suffered much from the depredations of the Scythians and Cimmerians, must still have retained something of the high degree of civilization (fortified towns, irrigation works, fertile fields and vineyards) portrayed by the Assyrian Sargon II who marched through them in 714 B.C.

The newcomers were not able to achieve the power and independence that had in earlier centuries enabled their predecessors to resist the might of Assyria—an echo of this resistance is perhaps to be found in the legendary struggle between King Ara and Queen Semiramis related by Moses of Khoren (*q.v.*)—and they were rapidly incorporated first by Cyaxares in the Median empire and then annexed with Media by Cyrus of Persia to form part of the Achaemenian empire (*c.* 550). The new state is mentioned as Armina and Armaniya in the Bisitun inscription of Darius I and, according to Herodotus, formed part of the 13th satrapy, the Alarodioi forming part of the 18th. Xenophon in his *Anabasis* gives a description of the country in 400 which shows the local government to have been in the hands of village headmen, part of whose tribute to the Persian king consisted of horses. Although Alexander the Great never himself set foot in Armenia, which continued to be governed by Persian or native satraps, it became part of the Macedonian empire (331) and of the Seleucid empire which succeeded it (301).

The Artaxiads.—After the defeat of Antiochus the Great by the Romans in the battle of Magnesia (winter 190–189) the two Armenian satraps of Antiochus, Artaxias (Artashes) and Zariadres (Zareh), revolted, established themselves with Roman consent as kings of Greater Armenia and Sophene respectively and united their efforts to enlarge their domains at the expense of neighbouring rulers. These two kings were the creators of historical Armenia, and little more than a century later Strabo could record that the many different regions spoke one tongue. Artaxias built his capital Artaxata, on the Araxes (now Aras or Araks) river to the southwest of Lake Sevan (near the modern Yerevan); the capital of Sophene is named as Carcathiocerta by Strabo. An attempt to end the division of Armenia into an eastern and a western part was made about 165 B.C. when the Artaxiad ruler sought to suppress his rival, but it was left to Tigranes (Tigran) II the Great, who reigned from *c.* 94 to *c.* 56 B.C., to establish by his defeat of the Zariadrid Artanes and by his annexation of Sophene a unity that was to last for nearly 500 years.

Under Tigranes, Armenia ascended to a pinnacle of power unique in its history and became, albeit for a brief period, the strongest state in the Roman east. Extensive territories were taken from the Parthians who had previously held Tigranes hostage on the defeat of his father Artavasdes (Artawazd) II but who were now unable to halt his advance to the gates of Ecbatana and compelled to sign a treaty of alliance. The Transcaucasian states of Atropatene, Iberia and Albania had already accepted his suzerainty when in 83 B.C. the Syrians, tired of anarchy, offered him their crown. Tigranes penetrated as far south as Ptolemais (Acre). Deeming Artaxata too far north to serve as the capital of his new empire, the Armenian king founded a new one, Tigranocerta (Tigranakert; possibly Silvan, formerly Mayafarkin), nearer the centre of his domains. Although Armenian culture at the time of Tigranes was, as it had been and as it was fundamentally to remain for many centuries, Iranian, the testimony of Plutarch shows that Hellenic scholars and actors found a welcome at the Armenian court, while Tigranes' son Artavasdes III was the author of works in Greek. The Armenian empire lasted until Tigranes became involved, more by accident than design, in the struggle between his father-in-law, Mithradates VI of Pontus, and Rome. Lucullus, although he captured Tigranocerta in 69 B.C., failed to reach Artaxata, but in 66 Pompeius Magnus, aided by one of Tigranes' sons, succeeded and compelled the king to renounce Syria and other conquests in the south and to become an ally of Rome. It has been the fate of Armenia throughout a long and turbulent history to be a small state struggling to preserve its independence between two powerful neighbours; it now became a buffer state, and often a battlefield, between Rome and Parthia.

The Arsacids.—Both Rome and Parthia strove for a century to establish their own candidates on the Armenian throne until a lasting measure of equilibrium was secured by the treaty of Rhandeia concluded in A.D. 63 between the Roman general Corbulo and Tiridates (Trdat) whereby an Arsacid occupied the throne of Armenia, but as a Roman vassal. A dispute with Parthia concerning the Armenian throne led to the country's annexation by Trajan in A.D. 114, but his successor, Hadrian, withdrew to the Euphrates. A similar dispute resulted in the destruction of Artaxata by Marcus Aurelius' general Priscus in 163 and in the building of a new capital, Kainepolis (Vagarshapat; modern Echmiadzin). After Caracalla's capture of King Vagarshak and his unsuccessful attempt to annex the country in 216, his successor, Macrinus, recognized Vagarshak's son Tiridates II (Khosrov the Great in Armenian sources) as king of Armenia (217). Tiridates II's resistance to the Sassanids after the fall of the Arsacid dynasty in Persia (224) ended in his assassination by their agent Anak the Parthian (*c.* 238?) and in the conquest of Armenia by Shapur I, who placed a vassal king named Artavasdes on the throne (252). Under Diocletian, however, after Roman military successes, the Persians were forced to relinquish Armenia, and Tiridates III, the son of Tiridates II, who had been brought up in Constantinople, was restored to the throne under Roman protection (*c.* 287).

The reign of Tiridates III determined the course of much of Armenia's subsequent history. His conversion by St. Gregory the Illuminator and the adoption of Christianity as the state religion (*c.* 300) created a permanent gulf between Armenia and Persia, and the Armenian patriarchate became one of the surest stays of the Arsacid monarchy while it lasted and the guardian of national unity after its fall. The Mamikonian family, which played a similar role, also came to the fore in his reign with the aggrandizement of their domains as a recompense for their defense of the throne against a rebel feudal family. Tiridates' assassination by his own chamberlain in league with the *nakhararq* (barons) of Siuniq illustrates the turbulent and disloyal nature of many of the local nobles whose revolts and quarrels fill the pages of the Armenian historians.

The dissatisfaction of the *nakhararq* with Arsaces (Arshak) III led to the division of Armenia into two sections, Byzantine Armenia and Persarmenia (*c.* 390). The former, comprising about one-fifth of Armenia, was rapidly incorporated into the structure of the Byzantine empire. The latter continued to be ruled by an Arsacid in Dwin, the capital since the reign of Khosrov II (330–339), until the deposition of Artaxias IV and his replacement by a Persian *marzpan* (governor) at the request of the *nakhararq* (428). Although the Armenian nobles had thus destroyed their country's sovereignty, the cause of national unity was furthered by the development, after the invention of the Armenian alphabet by St. Mesrop (*q.v.*), of a national Christian literature; culturally, if not politically, the 5th century was a golden age (*see* ARMENIAN LITERATURE).

The Marzpans.—The Persians were not so successful as the Byzantines in their efforts to assimilate the strongly individualistic

Armenian people. The misjudged attempt of Yazdegerd II to impose Mazdaism (Zoroastrianism, or the worship of Ahura Mazda) upon his Armenian subjects did much to reunite them as a nation. In the war of 451, which resulted from this attempt, the Armenian *sparapet* (commander in chief) St. Vardan Mamikonian and his companions were slain at the battle of Avarayr, but the Persians renounced their plans to convert Armenia by force and deposed their *marzpan* Vasak of Siuniq, the archtraitor of Armenian history. The revolt of 481 led by Vahan Mamikonian, which lasted until 484 when the Hephthalite attack in the east forced the Persians to negotiate, secured religious and political freedom for Armenia in return for military aid, and with the appointment of Vahan as *marzpan* the Armenians were again largely the arbiters of their own affairs. Their independence was further asserted in 554, when the second Council of Dwin rejected the duophysite formula of the Council of Chalcedon (451), a decisive step which cut them off from the west as surely as they were already severed from the east.

In 536 Justinian had reorganized Byzantine Armenia into four provinces and by the suppression of the power of the Armenian nobles and by transfers of population he completed the work of hellenizing the country. In 591 its territory was extended eastward by the emperor Maurice as the price of re-establishing Khosrau II on the throne of Persia in place of the usurper Bahram Chobin. After transferring many Armenians to Thrace, Maurice, according to the Armenian historian Sebeos, advised the Persian king to follow his example and to send this "perverse and unruly nation, which stirs up trouble between us," to fight on his eastern front. During the war between the emperor Phocas and Khosrau, the Persians occupied Byzantine Armenia and in 612 appointed a series of *marzpans*, only to be ousted by Heraclius who, aided in his advance by the Armenians, captured Dwin and Nakhichevan in 623. In 628, after the fall of Khosrau, the Persians appointed an Armenian *nakharar*, Varaztirotz Bagratuni, as governor. He quickly brought Armenia under Byzantine rule but was exiled for plotting against Heraclius (635). The noble who was appointed governor in his place, Dawith Saharuni, was overthrown by his fellow nobles (638).

The Bagratids.—The first Arab raid into Armenia in A.D. 640 found the defense of the country in the hands of the Byzantine general Procopius and the *nakharar* Theodor Rshtuni; the latter successfully ambushed the invaders and then withdrew, but Procopius' attack was repelled. Unable to prevent the pillage of Dwin in 642, in 643 Theodor gained a victory over another Arab army and was named commander in chief of the Armenian army by Constans II. In 653, after the truce was concluded with Mu'awiya, then governor of Syria, Constans voluntarily surrendered Armenia to the Arabs, who granted it virtual autonomy and appointed Theodor as *ostikan* (governor).

Theodor's successor, Hamazasp Mamikonian, sided with Byzantium, but after 661 Arab suzerainty was re-established, although Byzantine-Arab rivalry and Armenian nationalism and reluctance to pay the tribute made the region a difficult one to govern. An unsuccessful revolt led by Mushegh Mamikonian (771–772) resulted in the virtual extinction of the Mamikonian family as a political force in Armenia and in the emergence of the Bagratuni and Artsruni as the leading noble families. The Arabs' choice in 806 of Ashot Bagratuni the Carnivorous to be prince of Armenia marked the beginning of the establishment of his family as the chief power in the land. The Bagratids were more diplomatic than the Mamikonians in their dealings with their foreign overlords. The governor Smbat Ablabas Bagratuni remained loyal to the caliph al-Mutawakkil when he sent his general Bugha al-Kabir to bring the rebellious *nakhararq* to submission, although he also was dispatched in 855 with the rest of the captive nobles to Samarra.

The election by the *nakhararq* of Smbat's son Ashot I the Great, who had been accepted as "prince of princes" by the Arabs in 862, to be king of Armenia in 885 was recognized by both the caliph and the emperor, and it was he who by his successful defense of his country against local Arab chieftains laid the foundations of a new golden age of Armenian history. Throughout the 10th century art and literature flourished. Ashot III ("the Merciful"; 952–977) transferred his capital to Ani (near modern Anipemza) and began to transform it into one of the architectural gems of the middle ages.

The Bagratids of Ani, who bore the title of *shahanshah* ("king of kings") first conferred by the caliph in 922 upon Ashot II the Iron, were not the sole rulers of Armenia. In 908 the Artsruni principate of Vaspurakan became a kingdom recognized by the caliph; in 961 Mushegh, the brother of Ashot III, founded the Bagratid kingdom of Kars; and in 970 the prince of East Siuniq declared himself king.

By the time of the Seljuk Turkish invasions in the 11th century the Armenian kingdoms had already been destroyed from the west. The important province of Taron had been annexed to the Byzantine empire in 968 by Nicephorus II Phocas, and the expansionist policy of Basil II finally extinguished Armenian independence. The possessions of David of Tayq were annexed in 1000 and the kingdom of Vaspurakan in 1022. In the latter year the Bagratid king of Ani, Yovhannes-Smbat, was compelled to draw up a will which made the emperor heir to his estates, and in 1045, despite the resistance of Gagik II, Ani was seized by Constantine IX Monomachus. The Byzantine conquest was to be ephemeral in the extreme: in 1048 Togrul led the first raid of the Seljuk Turks into Armenia, in 1064 Ani and Kars fell to Alp Arslan, and after the battle of Manzikert (1071) most of the country was in the hands of the invaders. In 1072 the Kurdish Sheddadids received Ani as a fief. A few native Armenian rulers managed to survive for a time in the Kiwrikean kingdom of Lori, the Siunian kingdom of Baghq or Kapan, and the principates of Khachen (Artzakh) and Sasun. In the 12th century many ex-Armenian regions became part of Georgia, and between 1236 and 1242 the whole of Armenia and Georgia fell into the hands of the Mongols. Armenian life and learning, centred around the church, continued as best it could.

Little Armenia.—On the collapse of Greater Armenia many Armenians emigrated to Georgia, to Poland and to Galicia, while others crossed into Cilicia, where at the end of the 10th century some colonies had settled. One of Gagik II's lieutenants, a certain Ruben, established himself about 1080 at Bardzrberd in the Taurus mountains, and another noble named Oshin at Lambron; the former became the founder of the Rubenid dynasty of barons and kings who ruled Cilicia until 1226 and the latter was the ancestor of the Hethumid dynasty which succeeded them and ruled until 1342. The barons Constantine I (1092–1100), Thoros I (1100–29) and Leo I (1129–39) greatly enlarged their domains at the expense of the Byzantines who had occupied the Cilician plain and by 1132 Vahka, Sis, Anazarbus, Mamistra, Adana and Tarsus were under Rubenid rule. Although John II Comnenus succeeded in annexing the whole of Cilicia during 1137–38, Thoros II (1145–68) recaptured the mountain fortresses and Mleh (1170–75), with the aid of the Turks, recaptured the cities of the plain and restored Armenian rule. Leo II (I) the Great (1187–1219), who had been the ally of Frederick I Barbarossa, received the royal crown from the latter's son Henry VI and Pope Celestine III and in 1199 was crowned king of Armenia in Tarsus by the cardinal Conrad von Wittelsbach. The Byzantine emperor lost no time in sending a crown also, but Little, or Lesser, Armenia was now firmly allied to the west.

Intermarriage with crusading families was common and Frankish religious, political and cultural influence, though resisted by the more nationalistic barons, was strong. Leo reformed his court and the administration of his kingdom on western models and many French terms entered the language: the *nakharar* became a baron, the *sparapet* a cunstabl. Little Armenia played an important role in the trade of the Venetians and Genoese with the east, and the port of Lajazzo (on the Gulf of Iskenderun) rivaled Alexandria. Leo II left no son and the throne passed to his daughter Zabel. Her first husband, Philip of Antioch, who despised his Armenian subjects and refused to accept the Armenian faith—Leo II's lip-service to Rome as the price of his coronation was largely ignored—was deposed by the barons, and the regent Constantine, baron of Lambron and a descendant of Oshin, arranged the marriage of Zabel to his son Hayton (Hethum) I (1226–69), the first of the Hethumid dynasty. According to Armenian chroniclers, Hayton

conceived the idea of employing the Mongols against the growing menace of the Mamelukes of Egypt; he was present with the Mongol army that entered Aleppo and Damascus in 1260, but the subsequent Moslem victory at Darbsak cost him dearly. His successors followed the same policy, but the Mongols were weakening and after their defeat in 1303 near Damascus were unable and unwilling to protect Cilicia against the Mamelukes. The latter's chief objective was the port of Lajazzo; having destroyed it a first time in 1322, in 1337 they compelled Leo V (IV) (1320–42) to undertake to demolish its fortifications.

On the death, without heir, of Leo V the crown passed to Guy de Lusignan, the eldest son of Hayton II's sister Zabel and her husband Amaury de Lusignan (Amalric of Cyprus). He was assassinated by the barons in 1344 for doctrinal reasons and the next two kings, Constantine IV and V, were elected from their own ranks. On the assassination of Constantine V the crown passed again to a Lusignan, to Guy's nephew Leo VI (V) (1374–75). By this time, as a result of the Mameluke advance, little remained of Armenia except Sis and Anazarbus; Lajazzo had finally fallen in 1347, and Adana, Tarsus and the Cilician plain in 1359. In 1375 the capital Sis fell to the Mamelukes and the last king of Armenia was captured; ransomed in 1382, he died in Paris in 1393. The title "king of Armenia" passed then to the kings of Cyprus, from them to the Venetians, and was later claimed by the house of Savoy, but from the end of the 14th century the history of Armenia as a separate state is replaced by the history of Armenians under foreign domination.

The Turkish Conquest.—After the capture of Constantinople by the Ottoman Turks in 1453 the Armenian bishop of Bursa, transferred to the capital with the rank of patriarch, was appointed political leader of the Armenians in the Ottoman empire. The Armenians thereby acquired, in addition to religious freedom, a large say in the management of their own affairs. Their numbers were increased at the beginning of the 16th century by the conquest of Cilicia and Greater Armenia.

On the death of Timur in 1405 the eastern Armenian regions had passed into the hands of the Turkmen grouped into two rival confederacies, the Kara-Koyunlu (Black Sheep) and the Ak-Koyunlu (White Sheep), until the defeat of the latter by the Persian shah Ismail I in 1502. Armenia again became the battlefield for the armies of two powerful neighbours, and in 1514–16 the Ottomans wrested it from Persian rule. During the war that broke out in 1603 Shah Abbas I strove to regain the lost territories, and in 1605, with the aim of stimulating trade in his dominions, he forcibly transferred thousands of Armenians from Julfa (in northwest Persia) to Isfahan (central Persia), where those who survived the march settled in the quarter known as New Julfa. At the peace of 1620, while the greater part of Armenia remained in Ottoman hands, Persia regained the regions of Yerevan, Nakhichevan and Karabakh. In the mountainous region of Karabakh a group of five Armenian maliks (princes) succeeded in conserving their autonomy and managed, during the struggle between Persia and Turkey at the beginning of the 18th century, to achieve a short period of independence (1722–30); despite the heroic resistance of David Beg, the Turks occupied the region, but were driven out again by the Persians under Nadr Kuli (the future Nadir Shah) in 1735.

Armenia and Europe.—At the beginning of the 19th century the Russians advanced into the Caucasus. In 1813 the Persians were obliged to acknowledge Russia's authority over Georgia, northern Azerbaijan and Karabakh, and in 1828 they ceded Yerevan and Nakhichevan. Contact with liberal thought in Russia and western Europe was a factor in the Armenian cultural renascence in the 19th century, and leading writers like Abovian and Raffi (*q.v.*) did much to awaken the national consciousness of the Armenians, who became increasingly impatient with foreign rule. In Turkey the Armenians benefited with the rest of the population from what measures of reform there were, and in 1863 a special Armenian constitution was recognized by the Ottoman government. But social progress in Turkey was slow and the Armenians in Anatolia were subject to many abuses. After the Russo-Turkish War of 1877–78, in which Russian Armenians had taken part, Russia insisted in the treaty of San Stefano that reforms should be carried out among the sultan's Armenian subjects and that their protection against the Kurds should be guaranteed. This demand was reiterated at the congress of Berlin, and the "Armenian question" became a factor in international politics in which Great Britain showed a particular interest.

The Hënchak (socialist) party was founded in 1887 and the Dashnaktzutiun (Dashnak, nationalist) party in 1890, and in the face of growing Armenian nationalism the Turkish and Russian governments became increasingly hostile toward their unruly subjects. In 1895, after the Turkish sultan Abdul-Hamid II had promised Great Britain, France and Russia to carry out reforms, large-scale systematic massacres took place in the provinces. In 1896, after the desperate occupation of the Ottoman bank by a group of 26 young Dashnaks, more massacres took place in the capital. In 1903 Russia confiscated the property of the Armenian Church. The greatest single disaster in the history of the Armenians came with the outbreak of World War I. In 1915 the Turks, regarding the Armenians, despite pledges of loyalty, as a dangerous foreign element with friends among the enemies who had launched a campaign against the Dardanelles and with brothers in the Russian armies on their eastern front, decided to deport the whole Armenian population of about 1,750,000 to Syria and Mesopotamia. The operation was carried out with the utmost barbarity. It is estimated that about 600,000 Armenians died or were massacred en route. About one-third escaped deportation.

In 1916 the Turkish Armenian regions were captured by the Russians but in 1918, after the Russian Revolution of 1917, the Armenians, who continued the struggle against the Turks, were forced to fall back to the prewar Russo-Turkish border.

(C. J. F. D.)

Short-Lived Independence.—Together, on April 22, 1918, the Georgians, Armenians and Azerbaijanis had formed a Transcaucasian federal republic. On May 26, 1918, however, this was broken up into three independent republics. On June 4, 1918, R. I. Kachaznuni and A. I. Khatisian, both of the Dashnak party, who were respectively premier and foreign minister of the republic, were compelled to sign a peace treaty with Turkey at Batumi, by which Armenia lost Kars and its boundary with Turkey was fixed on the Arpa and Aras rivers (*i.e.,* the pre-1878 Russo-Turkish frontier). This treaty, however, was not ratified because of the military collapse of the Ottoman empire. After the Mudros armistice (Oct. 30, 1918) the Allied powers controlled the Black sea and this enabled them to establish direct contact with the Transcaucasian republics. The Turks were forced to withdraw their troops from the Armenian republic to the pre-1914 Russo-Turkish frontier. Soon afterward Armenia was involved in territorial disputes and in some fighting with both Georgia (for the Borchalo, now Marneuli, district) and Azerbaijan (for the Karabakh district). The British, politically in control of Transcaucasia, tried to arbitrate without recognizing the existing local governments. In Nov. 1919 the Soviet Russian government, having disposed of Gen. A. I. Denikin's White Russian army, concluded its first agreement with the Turkish nationalist government of Ankara. The Allies countered on Jan. 15, 1920, by the *de facto* recognition of the three Transcaucasian republics. Less than four months later Azerbaijan was conquered by the Red army and this was followed in May by an abortive Communist rising in Armenia.

The Allies were sponsoring the formation of a single Armenian state uniting Russian and Turkish Armenia. Great Britain and France hoped that the United States would accept a mandate over Armenia, but the U.S. senate declined such a responsibility (June 1, 1920). Nevertheless, on Aug. 10, 1920, the Allies recognized the Armenian republic *de jure* by admitting its representatives to sign the peace treaty of Sèvres with Turkey.

The treaty of Sèvres recognized Armenia as a "free, independent state," and Pres. Woodrow Wilson was asked to fix the boundary between Armenia and Turkey. On Nov. 22, 1920, he announced a line which awarded to Armenia Trabzon (Trebizond), Erzincan, Erzurum, Mush and Van, an area of about 40,000 sq.mi. within the pre-1914 Turkish frontier.

Both the treaty of Sèvres and Wilson's award remained a dead

letter. The fate of Armenia was decided by the armed forces of Soviet Russia and nationalist Turkey. At the end of Sept. 1920 the Turks attacked the Armenian republic; at the same time the Russians advanced from Azerbaijan. On Dec. 2, 1920, a peace treaty between Armenia and Turkey was signed at Alexandropol (Leninakan) which not only annulled the provisions of the treaty of Sèvres concerning Armenia but also stripped from it the Kars district which was Russian between 1878 and 1914. In the Alexandropol treaty the Armenian signatory recognized that there were no Armenian majorities anywhere in Turkey.

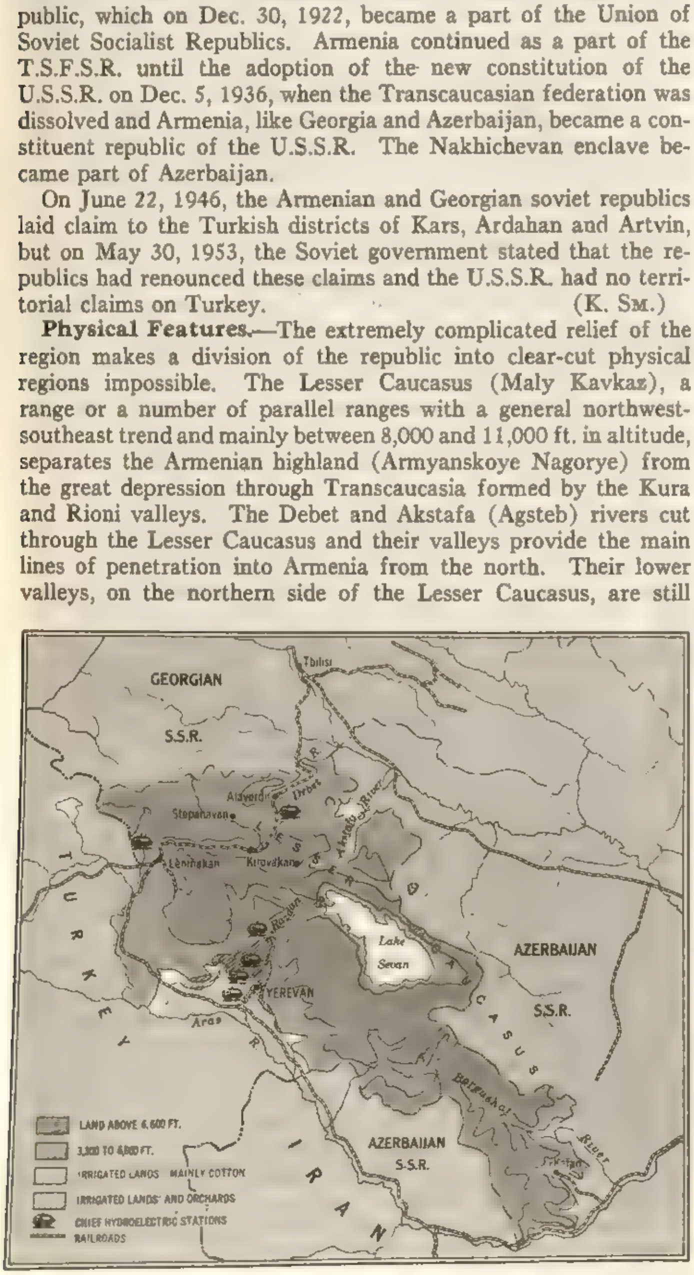
THE ARMENIAN SOVIET SOCIALIST REPUBLIC

On the same day that the Alexandropol treaty was signed the Armenian council of ministers at Yerevan ceded authority to Gen. Dro Kanayan, commander in chief. The next day (Dec. 3, 1920) a new government composed of Communists and Dashnakists proclaimed Armenia a Soviet republic. Shortly afterward the Dashnakists were eliminated from the government. One of them, S. Vratzian, led an armed anti-Communist rising in Feb. 1921, but since no help was forthcoming from abroad this ended in failure.

On March 12, 1922, Armenia, Georgia and Azerbaijan were combined to form the Transcaucasian Soviet Federated Socialist Republic, which on Dec. 30, 1922, became a part of the Union of Soviet Socialist Republics. Armenia continued as a part of the T.S.F.S.R. until the adoption of the new constitution of the U.S.S.R. on Dec. 5, 1936, when the Transcaucasian federation was dissolved and Armenia, like Georgia and Azerbaijan, became a constituent republic of the U.S.S.R. The Nakhichevan enclave became part of Azerbaijan.

On June 22, 1946, the Armenian and Georgian soviet republics laid claim to the Turkish districts of Kars, Ardahan and Artvin, but on May 30, 1953, the Soviet government stated that the republics had renounced these claims and the U.S.S.R. had no territorial claims on Turkey. (K. Sm.)

Physical Features.—The extremely complicated relief of the region makes a division of the republic into clear-cut physical regions impossible. The Lesser Caucasus (Maly Kavkaz), a range or a number of parallel ranges with a general northwest-southeast trend and mainly between 8,000 and 11,000 ft. in altitude, separates the Armenian highland (Armyanskoye Nagorye) from the great depression through Transcaucasia formed by the Kura and Rioni valleys. The Debet and Akstafa (Agsteb) rivers cut through the Lesser Caucasus and their valleys provide the main lines of penetration into Armenia from the north. Their lower valleys, on the northern side of the Lesser Caucasus, are still within Armenia. The Armenian highland, to the south of the Lesser Caucasus, is higher in the north and slopes toward the Aras river. It is broken by steep-sided ranges and interrupted by extinct volcanoes of which the highest is Mt. Aragats (Alagez), 13,418 ft. in altitude. A remarkable feature is the large Lake Sevan (*q.v.*), the surface of which is 6,279 ft. above sea level. The extreme southeast of the republic, drained mainly by the Bargushat (Vorotan) river, is very rugged. Least rugged is the Aras valley in the southwest. The Aras, which forms the international boundary between the U.S.S.R. (Armenia) and Turkey, drains most of the republic, including Lake Sevan via the Razdan (Zanga) river. About 50% of the republic is above 6,000 ft. and only about 3% is below 2,000 ft.



MAP OF ARMENIAN SOVIET SOCIALIST REPUBLIC SHOWING PHYSICAL FEATURES

Altitude affects climate in Armenia, contributing to a considerable diurnal range of temperature and, of course, making mean temperatures lower than might be expected at sea level in this latitude (41°–39° N.). Mountain barriers on almost every side, shutting off influence from already distant seas, produce large seasonal variations in temperature. Mean January temperature in the Armenian highland is around 32° F., while mean July temperature exceeds 80° F. Annual precipitation tends to increase with altitude, being only 8–12 in. in the lower parts of the Aras valley, 12–24 in. elsewhere in the highland but as much as 30 in. on the highest ranges.

A little deciduous forest is found in the more humid parts of the Lesser Caucasus ranges, but generally natural vegetation consists of xerophilous shrubs or mountain steppe plants in the higher parts, and steppe or even semidesert vegetation in the Aras valley. Among the chief wild animals in Armenia are the gopher (*Citellus xanthroprymnus*), the jerboa (*Alactaga williamsi*), the hamster (*Mesocricetus auratus*), the mole rat (*Spalax monticola*) and the fox (*Vulpes vulpes kurdistanica*). Wild boars are found in the remoter mountain districts. (J. P. Co.)

The People.—The Armenians are the descendants of a branch of the Indo-Europeans, represented by Herodotus and Eudoxus as related to the Phrygians who entered Asia Minor from Thrace, and the peoples of the ancient kingdom of Urartu upon whom they imposed their rule and their language. Known to the Persians as Armina, Arminiya-, and to the Greeks as Armenioi, the people call themselves Hay (pl. Hayq) and their country Hayastan, and look back to an eponymous hero Hayk. Both groups of appellations are of obscure origin; any connection of Hay with the land of Hayasa mentioned in Hittite sources is doubtful. Ancient Armenian writers call the Armenians descendants of Togarmah or Ashkenaz, the sons of Gomer, son of Japheth. F. von Luschan's postulation of an "Armenoid" race (brachycephalic, with flattened occiput, fleshy, convex nose) forming the basis of the population of Anatolia, Kurdistan, Syria and Iran has been rejected by R. Kherumian who considers the predominant element among the Armenians, who like all nations are mixed, to be Dinaric, a fact he takes to support the theory of the Thraco-Phrygian origin of the Armenians. The Armenian language is Indo-European (satem branch), but the phonetics and grammar have some features in common with the Caucasian languages. There are many cultural loans from Iranian, but the greater part of the vocabulary is unexplained; it is possible that some words derive from the extinct languages of the non-Indo-European substratum, but no convincing Urartian-Armenian "equations," for example, have been made. The standard language of the republic is Eastern Armenian (*rusahayeren*), which is written in the Armenian (Mesropian) character; the most important minority language is Azeri Turkish. The Armenians are traditionally monophysite Christians and belong to the Armenian Apostolic (Orthodox) Church, which has its centre at Echmiadzin (*q.v.*), the seat of the supreme catholicos. (*See* Armenian Language; Armenian Literature; Armenian Church.) (C. J. F. D.)

Population and Administration.—Armenians make up about 80% of the total population of the republic. The remainder consists of Azerbaijanians from the neighbouring republic, of Russians and Ukrainians, and of small groups of peoples, such as Kurds, long settled in the region itself. In 1959 the population of 1,763,048 was divided equally into urban and rural (in 1939 only

28.6% was urban). Of the 881,844 urban dwellers, 509,340 live in Yerevan (*q.v.*) and 108,446 in Leninakan, the only other town with more than 100,000 inhabitants.

Yerevan is the administrative, cultural and commercial centre. It is the seat of the presidium and the location of the state university, the academy of sciences and more than 40 technical and scientific institutes.

Economy.—After 1930 considerable industrial development took place, transforming the predominantly agricultural economy of Armenia. Several important mineral deposits are exploited, while a number of sizable hydroelectric power stations form the main source of energy for industrialization. Leninakan is the principal urban centre of the northwest and Stepanavan, Kirovakan and Kafan are small centres.

About 16% of the total area of Armenia is sown land (1,190,000 ac. out of 7,400,000 ac.). Part of this area, centred mainly in the Aras valley around Yerevan, is irrigated. The Aras, the Kasakh and Razdan from the north, and other rivers, feed irrigation channels. However, most of the sown area depends upon the generally inadequate precipitation. There is therefore a great contrast, in productivity per unit of area and in crops grown, between the limited irrigated lands and the rest of the sown area. Cotton, the mulberry tree, tobacco and the vine are grown on irrigated lands; wheat, which covers almost half of the sown area, and barley are among the nonirrigated crops. More than half of the remainder of Armenia consists of moderate to poor quality grazing land, which may be divided into winter pastures in the semiarid, nonirrigated parts of the Aras valley, middle altitude pasture used all the year and high summer pasture in areas above about 8,000 ft. Livestock products include meat, wool and milk. Unlike neighbouring Georgia and Azerbaijan, Armenia does not make any vital, special contribution to Soviet agriculture as a whole, and, apart from a limited surplus of fruits, cotton, wool and cheese, farming is largely organized to serve local needs.

Armenia has a large number of commercial mineral deposits. Copper, mined at Alaverdi and Kafan, is the principal mineral produced, but Armenia accounts for only a small part of the total Soviet output of this metal. Zinc and lead ores are also extracted near Kafan, and chrome ores near Lake Sevan. Armenia has a great variety of building stones.

In the absence of significant coal and oil deposits Armenia depends upon hydroelectricity as a source of energy. There are many favourable sites for small power stations with large vertical falls of water. In particular the Razdan river, which descends more than 3,000 ft. in its 50 mi. course between Lake Sevan and its confluence with the Aras, has several power stations. Lake Sevan makes a useful natural reservoir for the power stations and irrigation supply, but evaporation from its extensive surface is wasteful. It is planned to lower the level of the lake by cutting a tunnel from the western end into the Razdan, leaving only the deeper western part. The exposed lake bed will then be used for agricultural purposes. By the early 1960s most of the state and collective farms had been electrified.

Armenia has a wide range of light manufacturing, but, apart from the refining of copper and other metals heavy industry is hardly represented. Yerevan and Leninakan are the principal industrial centres, with light engineering, textile manufacturing and food processing.

Communications.—Armenia has about 300 mi. of railway. The principal line enters the republic from Tbilisi (Tiflis) in Georgia and climbs through the Lesser Caucasus range by the Debet valley to reach the Armenian highland near Leninakan. It then follows the Aras valley, descending southeastward into Azerbaijan, and runs most of the way close to the river and international boundary. Roads and tracks are the principal forms of communication in the rest of the republic. *See* also references under "Armenia" in the Index.

ARMENIAN ART. Very little is known about the pagan art of Armenia. The ruined temple of Garni is one of the rare survivals of this early period; the plan, the sculptured friezes, the pavement mosaic with mythological figures relate this monument to late Greco-Roman art. With the establishment of Christianity as the official religion in the first years of the 4th century, a new era began, and an art that had a truly national character was developed.

The principal periods of artistic activity correspond to those of national independence or semi-independence. The first and most fruitful period extends from the 5th century to the Arab conquest in the middle of the 7th century; the second, from the establishment of the Bagratid kingdom in the late 9th century to the Seljuk conquest in the middle of the 11th century; the third, from the end of the 12th to the middle of the 14th century, when the northern provinces were ruled by Armenian princes under Georgian or Mongol suzerainty, and an independent kingdom was established in Cilicia.

Architecture.—The feudal organization and the simultaneous existence of several local kings explain the erection of so many important buildings in several parts of the country; the absence of a strong centralized government and, consequently, of an official art may also have contributed to the great diversity of architectural types. The walls of the churches were faced, both inside and out, with carefully cut stone and the core filled with rubble.

The vaulted basilican plan, exemplified by the church of Ereruk, was abandoned fairly soon in favour of a centralized plan, crowned with a dome that had a typical conical roof. This type of church may already have been built in the 5th century, as evidenced by the foundations of the church of Echmiadzin, and from the 6th century on it became the predominant form. The monuments of the first period display imaginative variations of the basic, centralized scheme: different adaptations of a square buttressed by niches (Bagaran, St. Hrip'sime), or of the cross inscribed in a rectangle (St. Gayane, Mren); trefoils (Thalin), quatrefoils (Zvarthnots), hexagons, octagons or other polygonal types. The complexities of the inner disposition contrast with the massive simplicity of the exterior; the niches, the subsidiary chambers and even the main apse are often hidden in the thickness of the walls, the uniform surfaces of which are broken up by decorative arcades and by triangular slits or recesses marking the location of the inner divisions.

The architects of the second and third periods frequently reverted to the earlier models, but the general proportions tended to become more elongated and new structural features were developed.

At the cathedral of Ani, completed in 1001—the masterpiece of the architect Trdat, who was invited to Constantinople to repair the dome of Hagia Sophia—the clustered piers support pointed arches and the slightly pointed vaults are ribbed. In other churches, wall ribs, radiating arches or complex systems of cross ribs bear the weight of the stone web. Thus the problem of the vaulted stone structure received an earlier and different solution in Armenian art than it did in Gothic art.

Armenian architecture holds an important place in the history of medieval art. As in other eastern Christian countries, the ultimate sources of the monuments may be discerned in the edifices of the late classical period or in those of Persia and Mesopotamia, but because of the preference given to certain architectural types, the significant modifications that were found for structural problems, the Armenian churches differ from those of the neighbouring countries and have their own individual character. (*See* BYZANTINE ARCHITECTURE.)

Sculpture.—The stone construction lent itself to carved decorations, and architectural sculpture was more extensively used in Armenia than in any other country of the near east except Georgia.

The reliefs of the 4th-century hypogeum at Aghts and those on numerous funerary steles antedating the Arab conquest show the early stages of stone sculpture. Beginning with the 6th century, and perhaps even earlier, floral and geometric motifs as well as figure representations were carved around the windows of the churches, between the arches of the blind arcades, on the lintels and the lunettes over the doors. Decorative ornaments became increasingly intricate in the later periods.

The outstanding example of architectural sculpture is the church of the Holy Cross, built in the early 10th century on the island of Aghthamar in Lake Van; this is the earliest medieval example, either in the east or in the west, of a stone building entirely covered with relief sculpture. Around the dome and on the four façades may be seen a variety of animals, vine and other floral scrolls, and large figures of saints and scenes from the Old Testament. The portrait of King Gagik, offering to Christ the model of the church he had erected, appears on the west façade. Such donor portraits, sometimes carved in the round as at Ani, were one of the characteristic features of the decoration of Armenian churches.

Painting.—Remnants of mosaics and frescoes show that, from an early period, the interiors of the churches were adorned with scenes from the Gospels, images of Christ, of the Virgin and of saints. But it is principally through illustrated manuscripts that the development of Armenian painting can best be studied. Though the earliest examples have disappeared, there is an almost uninterrupted series of significant works ranging from the late 9th to the 17th century. These are distinguished first by the richness and diversity of their ornamental designs; floral, geometric and animal motifs are painted in vivid colours on a gold background around the canon tables of the Gospel manuscripts, on the headpieces, in the margins and ingeniously adapted to the capital letters.

The iconography of the Gospel scenes is based on the types evolved in early Christian and Byzantine art, but the Armenian painters, especially those of the medieval kingdom of Cilicia, often displayed a marked independence and interpreted, in a more lively or dramatic manner, the age-honoured formulas. In the manuscripts of Greater Armenia two artistic trends can be discerned: one, more eastern in character, tends to simplify the human form and subordinate it to the ornamental interest; the other, more influenced by Byzantine art, results in a subtle blending of naturalism and stylization. This latter trend was predominant in Armenian Cilicia, where a flourishing school developed under the patronage of the court and of the church. The high artistic quality of the 13th-century manuscripts, in particular, places them in the first rank of medieval illumination. Through contacts with the crusaders and the Mongols, the painters of this period became acquainted with the art of the Latin west and of the far east, and this broadened horizon resulted in the production of richly imaginative works.

Manuscripts continued to be illustrated in the Armenian monasteries and in the various centres outside their native country where the people settled after the destruction of the kingdom of Cilicia. These works are often inferior to the products of the earlier period, but some original schools developed, for instance, at Khizan, south of Lake Van.

The 17th century witnessed a revival of ancient forms, skilfully executed, as well as interesting imitations of western art, especially in the illustrations of the Old Testament and of the Book of Revelation.

A few silver reliquaries and bindings of manuscripts of the 13th and 14th centuries, with figure representations, give an idea of the art of the goldsmiths and silversmiths, which was also widely developed in medieval Armenia.

ARMENIAN CHURCH, the national church of Armenia, whose official title is the Armenian Apostolic Church. It is frequently supposed to be monophysite in belief (*see* MONOPHYSITES) because it rejects the Council of Chalcedon (*see* below), but its doctrine on the person of Christ as stated in its own official formularies readily admits of orthodox interpretation.

History.—Armenian tradition ascribes the first preaching of Christianity in Armenia to St. Thaddaeus and St. Bartholomew. Such apostolic claims were commonly made as a matter of prestige in early centuries, and in this case the evidence is inconclusive. Eusebius' *Church History* refers to a bishop in Armenia during the reign of Decius (*c.* 250). But the conversion of the Armenian people was mainly due to St. Gregory the Illuminator (*q.v.*), from which fact the Armenian Church is sometimes termed Gregorian. Gregory preached in Armenia as a layman and converted King Tiridates in about 300. Armenia then became the first country to adopt Christianity as the state religion.

The history of the church reflects that of the nation. Situated between the two great powers of Byzantium and Persia, its attitude toward the councils of the church was affected by political influences. In Persia it faced the stronghold of the Nestorian heresy and in Byzantium the upholders of the orthodoxy of the Council of Chalcedon; in maintaining a dogmatic position independent of either, the Armenian Church symbolized the efforts of the nation to regain its own independence.

Gregory was ordained priest and consecrated bishop by Leontius of Caesarea (Anazarbus) about 300. It is not clear how far the new bishop was subject to the jurisdiction of Caesarea, but the continuation of the patriarchate in Gregory's family suggests considerable independence, and the connection with Caesarea was finally broken in 374. Early in the 5th century the catholicos Sahak (Isaac) the Great, a scholar skilled in Greek, encouraged the monk Mesrop (*q.v.*) who invented an alphabet for writing the Armenian language, and together they began to translate into Armenian a series of Greek and Syriac theological works as well as the books of the Bible. (*See* ARMENIAN LITERATURE.)

In 451, when the Council of Chalcedon promulgated the orthodox doctrine of the two natures of Christ, Armenia was not represented, being politically under the control of the Persians and engaged in a fierce struggle against Zoroastrianism. In about 632 the Armenian synod of Karin (Erzurum), in the presence of the

Byzantine emperor Heraclius who had conquered the Persians, reached theological agreement with the Byzantine Church by avoiding any mention of Chalcedon, but in about 645 at the third Council of Dwin the one nature of Christ was again proclaimed.

The Arab conquest of Armenia, which soon followed, effectively cut the Armenians off from their Byzantine neighbour, who after condemning them at the Trullan council (692) tended to regard them as hated heretics. The two churches were also divided by certain different ritual and disciplinary practices, which further exacerbated the theological and national animosity between them. In the 9th century, when Armenia had received a measure of independence, the Byzantine patriarch Photius tried to persuade the catholicos to accept Chalcedon, but without success. Similar fruitless attempts were made in the following centuries. By the end of the 10th century the religious authorities of both churches, beginning with the Byzantines, were rebaptizing those members of the other church residing in their territory. It then became necessary for Armenians living within the Byzantine empire to have Armenian bishops of their own.

During the period of the crusades, most of which passed through Armenian territory, the Armenian Church tried to come to agreement with the Latins, who made a number of converts and continued to work in the area. The Armenian Church was represented at the Council of Ferrara-Florence (1438–*c.* 1445), where its delegates signed the decree of union, but this act was repudiated by the Armenian Church as a whole.

After the Turks had conquered Constantinople (1453) they appointed Hovakim of Bursa as Armenian patriarch of Constantinople (1461). Through him and his successors the Armenian church and nation were, together with other monophysite churches in the Ottoman empire, governed as a minority community, the *Ermeni milleti.*

From the 18th century onward the Latins were active in proselytization, and in 1717 Mekhitar of Sebastia (Sivas) went to San Lazzaro outside Venice and established there a colony of Armenians, called Mekhitarists (*q.v.*), in communion with Rome. Protestant proselytization began in the 19th century, but neither Latins nor Protestants affected more than a small minority of Armenians. From 1894 to 1917 the Armenian people suffered from periodic massacres by the Turks, which pitifully reduced their numbers. The supreme catholicos of the Armenian Church now resides at Echmiadzin in Soviet Armenia. There are strong Armenian minorities in both Constantinople and Jerusalem, where they are allotted a portion of the old city and share the church of the Resurrection (or Holy Sepulchre) with the Greeks and the Latins. Armenians have emigrated to most parts of the world, and colonies of them are settled chiefly in Iran, the middle east, eastern Europe, France and North and South America.

The Armenian Church is identified closely with the Armenian people, and through it the national consciousness has mainly been expressed. It has played an active part in common Christian activity in the World Council of Churches and it has had particularly friendly relations with the Anglican churches.

Doctrine.—The Armenian Church, together with the other eastern churches, repudiates the western doctrines of purgatory, the juridical primacy of the pope and the double procession of the Holy Spirit. It accepts the first three ecumenical councils, but differs from the Orthodox Eastern Church as well as from the western churches in rejecting the fourth (Chalcedon, 451), which promulgated the doctrine of Christ's two natures (*see* COUNCIL). It holds that this council was not fully ecumenical, because certain eastern churches were not represented there. It believes that if Christ has two natures then he must be two persons, and it agrees with the much-quoted formula *Mia physis tou theou sesarkomene* ("one incarnate nature of the godhead"), which was composed by Cyril of Alexandria before the word *physis* ("nature") had acquired the precise sense in which it was later used by the orthodox in their controversies with the monophysites. The Armenian Church anathematizes Eutyches (*q.v.*), the originator of monophysitism, as well as Nestorius. Its creed (an Armenian redaction of the so-called commentary, wrongly ascribed to Athanasius, on the Nicene Creed), which it has used since the 6th century, includes the statement "by whom [the Holy Spirit] he [the Logos] took body, soul and mind and everything that is in man, truly and not in semblance," a phrase inconsistent with full monophysite belief.

Organization and Customs.—The Armenian Church has four patriarchates, two of which have the dignity of catholicates. The catholicos of Sis resides at Antilyas near Beirut and has jurisdiction over Lebanon, Cyprus and parts of Syria. There is a patriarch of Jerusalem as well as of Constantinople. Only the supreme catholicos consecrates bishops for the whole church; the catholicos of Sis consecrates only for his own area. Clergy who wish to marry must do so before ordination; otherwise they must remain celibate. Bishops are chosen from the unmarried clergy. Monasteries now exist only as seminaries for the training of the clergy. The laity substantially outnumber the clergy in the councils electing bishops and patriarchs, and have always taken full part in discussions on doctrine and discipline.

Armenians theoretically maintain seven sacraments, but extreme unction has fallen out of use. Unleavened bread and wine not mixed with water are used for Holy Communion; communion is in both kinds by intinction (*i.e.*, the bread is dipped into the wine), and reservation for the sick is practised. Divorce is occasionally permitted under canonical rules. Vestments and ceremonial show traces of Latin influence, though the liturgy (*q.v.*) is mainly that of St. Basil. The liturgical language is ancient Armenian. Armenian churches are usually rectangular in shape with an altar raised on a platform five or six steps above the level of the nave; only one liturgy is permitted on any one day. There are no statues in the churches, and icons are far less prominent than in Orthodox churches.

The Armenian patriarchate of Jerusalem continues, like other Eastern churches in the holy city, to keep the Julian calendar, which is 13 days behind the Gregorian. The rest of the Armenian Church, however, changed to the Gregorian calendar in 1922. Fixed feast days are kept on the nearest Sunday to their calendar date, save that Christmas, which is not a separate festival but is included in Epiphany as in the early Eastern Church, always falls on Jan. 6 except in the United States, where it too is kept on the nearest Sunday.

ARMENIAN LANGUAGE. The Armenian language is an independent member of the Indo-European family of languages which, spoken in a mountainous region, has never spread widely or permanently. It possesses great vitality despite many persecutions. It was not reduced to writing until the spread of Christianity in Armenia when, according to tradition, in the 5th century, an alphabet was drawn up to suit it.

In the language as then written were composed translations of the Bible and other pious works as well as original compositions such as that by Bishop Eznik. This language is still preserved as the ritual language of the Gregorian or Armenian Church and up to the 19th century was the language used by Armenian scholars.

The spoken language meanwhile evolved independently and in all parts of the country differed widely from the literary language. Lay writers used the forms current in their region, so that from the time of the crusades there are historic texts in the vulgar speech of the Armenian kingdom in Cilicia as then constituted. When in the 19th century modern literary languages appeared, there was great diversity in form.

Some Armenians were then Russian subjects, others under Ottoman rule, yet others under Persia. One literary language developed at Yerevan under Russian rule and was used by the numerous Armenians settled at Tbilisi (Tiflis). Another was formed at Constantinople, where from the days of the Byzantine empire there had been an important Armenian colony. Both these languages deliberately eliminated words brought in under Islamic and Turkish domination and replaced them by true Armenian

ARMENIAN ALPHABET

* Initially y as in yet; medially ĕ as in end (*Condĕmnation*)
† No equivalent sound in English; a strong guttural sound as in German *noch*
‡ No equivalent sound in English; a soft guttural sound similar to uvular r of French and German
§ Initially h as in hot; medially y as in beyond; finally y as in boy or else silent
‖ Initially v as in vote; medially o similar to second o in photo
¶ Rolled tongue-tip r as in Spanish *sierra*
♀ a. v as in revive
b. In combination with ու = o͞o as in poor
c. In combination with իւ = ü as in cure
1. Also formerly written as մ or մ
2. Also formerly written as յ
3. Also formerly written as Տ

words largely taken from the old written language, and thus in vocabulary both agree in many points. Pronunciation and grammar have diverged considerably though true to the general linguistic type. Thus in Yerevan Armenian, Jacob is pronounced *Hakob* and in Turkish Armenian is *Hagop*.

Armenian is the continuation of a group of Indo-European languages intermediate between Indo-Iranian (Aryan) and Greek but distinct from both. As a result of contact with other languages, Armenian has developed in its own way and is widely removed from the early Indo-European type.

The consonantal system coincides largely with that of the southern group of Caucasian languages, represented by Georgian. The so-called occlusive consonants, *p, t, k* and *b, d, g,* have undergone complete mutation, so that where Indo-European has a *d*, there is a *t;* thus the numeral *tasn* for ten corresponds to the ancient form *decem* as in Latin, *cf.* Armenian *hayr* ("father"), Gothic *fadar* and Latin *pater*.

The changes from the original form have been considerable as in the numerals "two" and "three," which in Latin are *duo* and *tre* and in Armenian are *erku* and *erekh*.

The grammatical forms are traceable to Indo-European origins but assumed new shapes. Thus grammatical gender had disappeared from Old Armenian. A good number of old words have been preserved, such as *kov* ("cow"), showing the mutation of *g* to *k*. The old form had a *g* as in the Sanskrit *gav*. Words of higher culture are mainly borrowed since Armenian has always been exposed to foreign influence. From the 3rd century B.C. to the 3rd century A.D. the country was ruled by a Parthian aristocracy, so that the language has many Iranian words. The terminology of Christianity came with the spread of the Syrian and Byzantine churches, and there are Greek words and, from the time of the crusades, French words.

ARMENIAN LITERATURE. There is evidence that a pagan oral literature of ritual songs, epic poems and plays existed in Armenia before the invention of the alphabet in the 5th century A.D., but owing to the zeal of the early Christian priests, little of this has been preserved. In his *History of Armenia* Moses of Khoren cites fragments of songs and poems composed about the god Vahagn (the Iranian Verethragna) and King Artavasdes which he says, were still sung in his day (5th–6th century A.D.). Apart from early court theatres on classical models (Plutarch mentions a performance of Euripides' *Bacchae* at the Armenian court and records that Artavasdes II [*c.* 53–34 B.C.] himself wrote tragedies histories and orations in Greek), primitive native plays or mimes were enacted by the *gusans* and *vardzaks* (male and female singers and dancers).

For about a century after their conversion to Christianity (*c.* 300), the Armenians had to rely for the scriptures and religious books upon works in Greek and Syriac that were unintelligible to the common people, and to remedy this St. Mesrop (Mashtotz) invented the Armenian alphabet (*c.* 410). The catholicos Sahak the Great and St. Mesrop, encouraged by King Vramshapuh (*c.* 392–414), formed a school of translators who were sent to Edessa and to Constantinople to procure and translate Syriac and Greek copies of the scriptures and other important works.

Much of the literary activity of the 5th century, the golden age (*oskedar*) of Armenian literature, was devoted to such translations; original works, however, although some of those traditionally ascribed to this century are almost certainly later compositions, are not wanting. The masterpiece of classical Armenian writing is the *Refutation of the Sects* of Eznik Koghbatzi. This is a polemic work, composed partly from Greek sources, in defense of orthodox Christian belief against—and thereby providing valuable information about—pagan Armenian superstitions, Iranian dualism, Greek philosophy and the Marcionite heresy. Its pure classical style is unsurpassed in Armenian literature.

The writing of history is the principal genre in ancient Armenian literature, and many histories are attributed to the 5th century

The best-known is the *History of Armenia* of Moses of Khoren (*q.v.*). The *History of Armenia* of Faustus (Phaustos) Biuzandatzi belongs to the 5th century, although he has been said to have been a Byzantine of the 4th century writing in Greek. From this lively and honest work, of which only books covering the brief period *c.* 316–390 are extant, a passage is quoted by the 6th-century historian Procopius. Toward the end of the 5th or at the beginning of the 6th century Ghazar Pharbetzi wrote a *History of Armenia* (388–485) having been requested by the *marzpan* Vahan Mamikonian (*c.* 485–505) to continue the history of Faustus. To some extent a panegyric of the Mamikonian family, it is nevertheless the best factual history after that of Faustus.

As well as these predominantly political histories, others were written dealing with religious affairs and hagiography. A work by Agathangelus relates the life of St. Gregory (Grigor) the Illuminator. Speculation has been rife about the identity of its author, ranging from the traditional view that he was the Greek secretary of King Tiridates (Trdat) II (278–332) and wrote in Greek in the 4th century, to the view that Agathangelus is not the name of a person, but an epithet ("bearer of good tidings") used of St. Gregory. The work was probably written in Armenian in the 5th century.

To the 6th century belongs Bishop Peter (Petros) of Siuniq (547–556), whose principal work was a *Panegyric on the Mother of God.* From the end of the 5th to the 7th century the so-called Hellenistic school translated many Greek works. Most of the works attributed to a certain David the Invincible belong to this period. The Midas touch of Armenian tradition has made of this enigmatic David a golden age disciple of Sahak and Mesrop who studied in Athens and Constantinople, but his identity is not known. The language of the Hellenistic school was artificial in character. Of original literature, the 7th century produced the important *History of Heraclius* by Bishop Sebeos, an account of the war between Byzantium and Khosrau II of Persia and of the Arab conquest. Anania Shirakatzi wrote works on arithmetic, astronomy and possibly the geography once attributed to Moses of Khoren. In the 8th century Ghevond Vardapet wrote a *History of the Caliphs,* and Catholicos John IV of Odzun (717–728), various theological works.

In the 10th and 11th centuries, which witnessed the maturity of the independent Bagratid kingdom of Armenia, the Artsruni kingdom of Vaspurakan and the kingdom of Siuniq, Armenian literature, art and architecture flourished more freely than at any time since the 5th century. The principal literary figure of the 10th century was St. Gregory Narekatzi (951–1003), the first great Armenian poet, renowned for his mystic poems and hymns as well as for such prose works as the *Commentary on the Song of Songs.* Earlier in the same century, Thomas (Thovma) Artsruni wrote a *History of the House of Artsruni* which, in spite of its family bias, is the chief source of information on the history of Armenia down to 936; an anonymous writer continued the work to 1121. The *History of Armenia* by Catholicos John VI Draskhanakertzi (897–925) is of great value for its account of Arab relations with Armenia, for the author was himself an important participant in the later events he describes. At the turn of the 10th to 11th centuries Bishop Ukhtanes wrote a *History of Armenia* and a *History of the Schism between the Georgians and Armenians.* The beginning of the 11th century saw the completion of the reliable and well-written *Universal History* of Stephanos Asoghik. The *History of Armenia* by Aristakes Lastivertzi, relating the fall of the Bagratid kingdom (1045), the destruction of Ani (1064) and the victories of the Seljuks, is almost as much a prose elegy as a history.

After the political collapse of Greater Armenia at the end of the 11th century, the cultural centre shifted to Little or Cilician Armenia. Literature did not cease to be written in the occupied territories, however, and Armenian literature may thereafter be divided into a western and an eastern branch. In both regions works began to be written in the spoken as well as the classical language. The greatest poet of the 12th century in Cilicia was Catholicos Nerses IV Shnorhali ("the Gracious," 1102–1172), the author of many poems and hymns. In prose one of his important works is an *Epistle on the Question of Union With the Greek Church.* Catholicos Grigor IV Pahlavuni (1173–1193), nephew and successor of Nerses Shnorhali, composed an *Elegy on the Capture of Jerusalem* and various epistles. In the east, the priest Samuel of Ani wrote a *Chronicle* (to 1179). In Caucasian Albania, Mkhithar Gosh (1133–1213) compiled a *Lawbook* which became a basis for subsequent Armenian law.

In the 13th century, eastern Armenia proved at least as fertile in literary production as Cilicia. Kirakos Gandzaketzi's *Concise History*, Vardan Vardapet's *Universal History* and the *History of the Archers* (formerly attributed to Malachia the Monk but now to Gregory of Akner in Cilicia) are valuable for the history of the Mongols. Mkhithar of Ani wrote a *Universal History* of which only a fragment remains. In Cilicia, Vahram Rhabuni composed a *Rhymed Chronicle* of the Rubenid dynasty down to the reign of Leo III (1269–1289) at the latter's request, and Smbat the Constable (1208–1276) wrote a *Chronicle of Little Armenia* (from 952 to 1274, continued anonymously to 1331) and a translation of the *Assises d'Antioche*, the French text of which is lost.

Whereas in Cilicia, in the 14th century, many laymen took to writing, all the principal works of the eastern regions were produced by the clergy. A *History of Siuniq* was written by Stephanos Orbelian (d. 1304), archbishop of the province, who also wrote a *Lamentation on the Cathedral of Echmiadzin.* Gregory Tathevatzi (1346–1411) wrote a book of *Questions and Answers* dealing with Manichaean and Islamic "errors," and a collection of sermons. The monasteries of Tathev and Gladzor in Siuniq and Nor Getik in Caucasian Albania were, like Skevra and Akner in Cilicia, important centres of literary activity during this period, while the Uniate monastery of Krnai was zealous in the translation of Latin works, including the *Summa* of St. Thomas Aquinas (1347). Of the poets, the most important was Frik (*c.* 1236–1315).

The events of the last quarter of the 14th century—the Cilician kingdom fell to the Mameluks in 1375 and Timur invaded the east in 1385—ushered in a long period of political and cultural decadence in Armenia, but despite unfavourable conditions, some works of importance were produced. Thomas of Metsob (1379–1446) wrote a *History of Timur;* Amirdovlath of Amasia (*c.* 1415–1496), living in Constantinople, henceforth the centre of western Armenian culture, wrote two medical works compiled from Arabic, Greek and other sources; and Araqel Siunetzi, abbot of Tathev (fl. 1407), wrote various works in prose and verse, his chief poem being the *Book of Adam* which has been called (generously) "an oriental *Paradise Lost.*"

The besetting gloom of the period of decadence was illumined from the 16th to the 18th centuries by the rise of a number of popular bards or troubadours called *ashugh* (Arabic *ashiq* "lover") who, though to a large extent subject to foreign influence in matter, style and vocabulary, composed verses of merit. The two outstanding troubadours of this period were Nahapet Kuchak (d. *c.* 1592), one of the rare Armenian poets to sing unambiguously of profane love, and, most famous of all, Aruthin Sayadian, called Sayat-Nova (*q.v.*). Many folk songs—laments, lullabies, love songs, marriage songs, work songs, etc.—have been preserved in contemporary manuscripts. A folk epic, *Sasuntzi Davith* ("David of Sasun"), said by some to date from the 8th to 10th centuries, was current among the people, and was first written down in 1873. In the 17th century Araqel of Tabriz, a monk at Echmiadzin, wrote a *History* of the years 1602 to 1660, dealing with the events in Armenia during the Perso-Turkish wars and the forced emigration of Armenians to Persia under Shah Abbas I. Oskan of Yerevan (1614–1675), who was born at the new Armenian colony of New Julfa at Isfahan, printed the first Armenian Bible at Amsterdam in 1666, but the first Armenian printed book, a directory of church feasts, had appeared in 1512. Eremia Chelebi Kömürjian (1637–1695) wrote various works on Ottoman history and a description of Istanbul, as well as some poems.

The 18th century witnessed an Armenian cultural and intellectual renaissance symbolized to some extent by the establishment of the Uniate congregation of Mekhitharists at Venice, and later also at Vienna; both the classics and original works of scholarship were—and still are—printed on their own presses. By the middle

of the 19th century, the soil was prepared for a reburgeoning of Armenian literature; contributory factors were the temporary improvement in the lot of the sultan's Armenian subjects and the increase in the number of national schools and newspapers. The Armenian language, however, was in a chaotic state, and the question as to which form should serve as the vehicle for the new ideas of the time led to controversies, both in Turkish and Russian Armenia, between the champions of the old classical language and those of the modern spoken languages. Eventually the latter prevailed, with the result that the eastern literature is written in the so-called Ararat dialect (*rusahayeren*) and that of the west in the dialect of Istanbul (*dachgahayeren*). For their models, and for many of their ideals, the Armenian writers looked to Europe (those of the west to France, those of the east to Russia) and the divers literary fashions of Europe found an echo in Armenian writing. Among western authors, Tovma Terzian (1840–1909), Mrktich Peshikthashlian (1828–1868), Petros Durian (1851–1872), Daniel Varuzhan (1884–1915) and Vahan Tekeyan (1877–1944) composed lyrical poetry; in prose Hakob Paronian (1842–1891) and Eruand Otian (1869–1926) were outstanding satirical novelists, and Grigor Zohrab (1861–1915) the author of realist short stories; the theatre, although the Mekhitharists had paved the way with historical plays and comedies, was perhaps best represented by Paronian, whose comedies (*e.g.*, *The Dowry*, *Master Balthazar*, *The Oriental Dentist*) are still popular.

The serious novel, comparatively weak in western Armenian literature, was strongly represented in Russian Armenia where it became the vehicle for Armenian moral, social and political aspirations. Khachatur Abovian (1805–48), called the "father of modern Armenian literature," wrote his *Wounds of Armenia* in 1840, although it was not published until after his death, in 1858. The most celebrated Armenian novelist is Hakob Meliq-Hakobian or Raffi (*q.v.*). Among the eastern poets Hovhannes Thumanian (1869–1923) must be mentioned; he wrote both lyric and narrative poems and his masterpiece, the short epic *Anush*, full of songs that have become well-nigh traditional, was early adapted as an opera. The most outstanding Armenian dramatist was Gabriel Sundukian (1825–1912), whose comedies (*Hullabaloo*, *Pepo*, *The Broken Hearth*) portray the contemporary Armenian society of Tbilisi in whose dialect most of them were written.

The rapid decline of Istanbul as the principal western Armenian literary centre (after the massacres of the first quarter of the 20th century) brought about a new period of decadence in Armenian literature, although the Armenians of the diaspora continued to write in Paris, Beirut and Boston. Some Turkish Armenians fled to the east where they enjoyed a certain degree of autonomy and where, after the foundation of the Armenian Soviet Socialist Republic in 1936, national literature was encouraged, and controlled, by the state. There were numerous eastern Armenian writers of varying quality, as for instance, the poet Avetiq Isahakian (1875–1957), but eastern literature tended toward monotony. The university and the Academy of Sciences of Yerevan, however, did much to encourage the study of Armenian literature.

ARMENTIÈRES, a town in northern France, in the *département* of Nord, is situated in flat country on the Lys close to the Belgian frontier 10 mi. W.N.W. of Lille by road. Pop. (1954) 24,274. The town, entirely rebuilt after destruction in World War I, presents a uniform appearance with its red-brick buildings. There is an annual fair in September. Armentières is on the main railway from Lille to Dunkerque and Calais. Flax and cotton, beer, and machinery are produced. Armentières was two miles behind the battle line throughout World War I and from April until Sept. 1918 was in German possession. The marching song about the mythical "Mademoiselle from Armentières," sung by British and U.S. troops, dates from this period. During World War II the town was bombed and was occupied by the Germans from May 1940 until Sept. 1944.

ARMERIA, a genus of plants of the north temperate zone, belonging to the Plumbaginaceae family and consisting of about 60 species of small perennial herbs, many of which are commonly known as thrift or sea pink. They have rosettes of narrow evergreen leaves on the ground and simple naked scapes terminated by a head of pink, lilac or white flowers. *A. maritima* (formerly *Statice armeria* and *S. vulgaris*) is the thrift so widely grown in beds, borders and rock gardens. It succeeds in almost any well-drained soil in the full sun, being hardy and free growing. Many of the species and their varieties hybridize freely and much of the horticultural material is a mixture of various forms. Propagation is by division of clumps and by seeds. (J. M. Bl.)

ARMFELT, GUSTAF MAURITZ, Count (1757–1814), Swedish statesman prominent both in diplomacy and in military affairs, was born at St. Mårtens near Turku in Finland on March 31, 1757. Appointed gentleman to the crown prince Gustavus II Adolphus in 1781, Armfelt made a brilliant career at the court. He was employed by Gustavus III of Sweden in the negotiations with Catherine II of Russia (1783) and with the Danish government (1787) and was one of his most trusted and active counselors during the Russian war of 1788–90. He displayed great valour in the field. In 1788 when the Danes invaded Sweden and threatened Göteborg, Armfelt, under the king's direction, organized the Dalarna levies. He remained faithful to Gustavus when nearly all the nobility deserted him; brilliantly distinguished himself in the later phases of the Russian war; and was the Swedish plenipotentiary at the peace of Värälä (1790). During Gustavus III's last years his influence was paramount, though he protested against his master's headstrong championship of the Bourbons.

On his deathbed Gustavus III (1792) entrusted his infant son to Armfelt and made him a member of the council of regency; but the duke-regent Charles (afterward Charles XIII) sent Armfelt as Swedish ambassador to Naples to get rid of him. From Naples Armfelt communicated with Catherine II, urging her to make a military demonstration in favour of the Gustavians. The plot was discovered by the regent's spies, and Armfelt only escaped with the assistance of Queen Caroline of Naples (1794). He then fled to Russia. When Gustavus IV attained his majority, Armfelt was rehabilitated and sent as Swedish ambassador to Vienna (1802), but was obliged to quit that post two years later for sharply attacking the Austrian government's attitude toward Napoleon Bonaparte. From 1805 to 1807 he was commander in chief of the Swedish forces in Pomerania, where he retarded the French conquest.

After the deposition of Gustavus IV (1809), Armfelt was the most courageous supporter of the crown prince Gustavus. Expelled from Sweden in 1811, he found refuge in Russia, where he obtained great influence over the emperor Alexander I. He contributed more than anyone else to the erection of the grand duchy of Finland as an autonomous state and participated in the planning of the Russian defensive campaigns against Napoleon and in the conference between Alexander and the Swedish crown prince (Bernadotte; the future Charles XIV John) at Turku in Aug. 1812. He died at Tsarskoe Selo, on Aug. 19, 1814.

ARMIDALE, a city in Sandon county, situated on the New England tablelands, New South Wales, Austr., lies 350 mi. N. of Sydney and 287 mi. S. of Brisbane by road. Pop. (1954) 8,661. The plateau, consisting of Silurian rocks buttressed by granite, is bounded on the east by steep escarpments and rugged country. In spite of its latitude (30° 32′ S.), the altitude of Armidale (3,265 ft.) gives it a cool, bracing climate and a sufficient rainfall (mean annual 31–32 in.) derived mainly from the Pacific side. It is the centre of a thriving agricultural and pastoral area (sheep, cattle, fruit, etc.). Mining of tin, gold and antimony is also carried

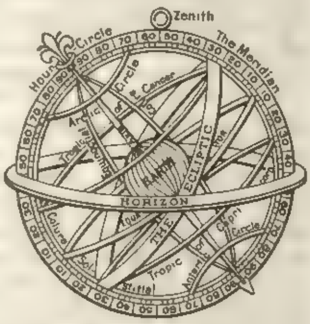
on locally, though to a much lesser extent than formerly. Hydroelectric power is generated from the falling waters of the Oaky river.

Climate, scenery and a halfway position on the main railway line from Sydney to Brisbane (to both of which there are also air services) have helped to make Armidale an educational, cultural, ecclesiastical and sporting centre. It possesses fine schools, a university, a teachers' training college (with a notable art gallery) and an Anglican and a Roman Catholic cathedral. The town was first laid out in the 1840s and became a city in 1884. (Ro. A. B.)

ARMIGER: *see* Esquire.

ARMILLARY SPHERE, an ancient astronomical device for representing the great circles of the heavens, including in the complete instruments the horizon, meridian, equator, tropics, polar circles and an ecliptic hoop. It is a skeleton celestial globe, with circles divided into degrees for angular measurement. In the 17th and 18th centuries such models, either suspended, rested on a stand or affixed to a handle, were used to show the difference between the Ptolemaic theory of a central earth and the Copernican theory of a central sun.

The earliest known complete armillary sphere with nine circles is believed to have been the *meteōroskopion* of the Alexandrine Greeks (*c.* A.D. 140), but earlier and simpler types of ring instruments were also in general use. Ptolemy in the *Almagest* enumerates at least three. The simplest of all was the equinoctial armilla, a ring of bronze fixed in the plane of the equator. At Rhodes and elsewhere the arrival of the equinoxes was noted by observing when the shadow of the upper half of the ring exactly covered the lower half. Similarly, the solstitial armilla, a double ring erected in the plane of the meridian with a rotating inner circle, was used for measuring solar altitudes, and probably by Eratosthenes (*c.* 276–*c.* 192 B.C.) for measuring the obliquity of the ecliptic. Hipparchus is stated to have used (146–127 B.C.) a sphere of four rings, and in Ptolemy's instrument, the *astrolabon*, there were diametrically disposed tubes upon the graduated circles, the instrument being kept vertical by a plumb line.



AFTER BLUNDEVILLE, "A PLAINE TREATISE . . . OF COSMOGRAPHIE," 1594

AN ARMILLARY SPHERE

The earth is equipped with a visible axis, and the imaginary circles of astronomy are represented by metal rings

The Arabs employed similar instruments with diametric sight rules or alidades, and it is likely that those made and used in the 12th century by Moors in Spain were the prototypes of all later European armillary spheres.

Sédillot, *Traité des Instruments astronomiques des Arabes* (1834); F. Nolte, *Armillarsphäre* (1922); G. R. Kaye, *Hindu Astronomy* (1924); E. Zinner, *Geschichte der Sternkunde* (1931). (R. T. G.; A. Po.)

ARMINIANISM, beginning early in the 17th century, a liberal reaction to the Calvinist doctrine of predestination, asserting that God's sovereignty and man's free will are compatible.

Jacobus Arminius (*q.v.*), Dutch Reformed theologian of the University of Leiden (1603–09), an irenic scholar, was unwillingly precipitated into a highly publicized debate with his colleague F. Gomarus (*q.v.*) concerning the Calvinistic interpretation of the divine decrees respecting election and reprobation. The point at issue was the relationship of the divine omniscience to the sovereign acts of God's love and wrath. Were the divine decrees of election and reprobation (as effective for every human being in the whole stream of human history) projected from the inscrutable mystery of the ultimate divine will? Or were these decrees predicated upon the omniscient divine foreknowledge of the freely willed response to or rejection of God's proffered love? Arminius sought to affirm the latter alternative, adding that the divine omniscience knows that the divine will effects sovereignty through a love that is so omnipotent as to suffer the contradictions of human rejection. (*See* also Predestination.)

In short, Arminius saw the divine will in terms of the power of love rather than of unmitigated force. This point of view is to be sharply distinguished from the assertion that the divine decrees are based on the foreknowledge of man's choice. It is, for Arminius, God's will as unceasing love that is ever the determinative initiator and arbiter of human destiny. The theological movement designated Arminianism, however, while precipitated by the long controversy at the University of Leiden, in retrospect failed to apprehend the discriminative nuances of Arminius.

Dutch Arminianism was originally articulated in the Remonstrance (1610), a theological dictum written by J. Uytenbogaert, signed by 45 ministers and submitted to the states-general. The Synod of Dort (Nov. 13, 1618–May 9, 1619) was called by the states-general to pass upon the Remonstrance (*see* Dort, Synod of). Eminent defenders of this document were Simon Episcopius (*q.v.*), Philipp van Limborch and Hugo Grotius (*q.v.*), none of whom had come under the tutelage of Arminius. The "five points" of the Remonstrance asserted: (1) election (and condemnation in the day of judgment) was conditioned by the rational faith or nonfaith of man; (2) the atonement, while qualitatively adequate for all men, was efficacious only for the man of faith; (3) unaided by the Holy Spirit, no person is able to respond to God's will; (4) grace is not irresistible; and (5) believers are able to resist sin but are not beyond the possibility of falling from grace.

The import of the Remonstrance, understood (deceptively) as the theological structure of Arminianism, was that it apparently relieved the divine sovereignty of efficacious responsibility in the process of redemption. Elements of Renaissance humanism, with its affirmation of man's inalienable initiative and self-determination, found in it a brilliant Protestant theological articulation. The crux of this Remonstrant Arminianism lay in the assertion that human dignity requires an unimpaired freedom of the will. This freedom is in no sense mitigated by divine acts or decrees. While reason proposes validly live options for the decisions of free will, some of these options, if they are to appeal to faith, must be provided by grace alone; and this grace is always resistible. The will acts as guided by reason. Hence, the freedom of the will is expressed in decisions of faith that are grounded in rationally accepted options; these options, in turn, may be actualized only by the immanent aid of the Holy Spirit, granted as a superadded gift of prevenient grace (*i.e.*, grace [*q.v.*] given freely by God, and unmerited, so that the person who receives it may be led to choose the good).

Opponents discerned that in the delineation of this process, for Remonstrant Arminianism, it is reason rather than alienable love that is chiefly determinative of human choice. Furthermore, this analysis provided *de facto* denial of both the supralapsarian and infralapsarian views of the divine decrees of predestination (*q.v.*), and these views had become such acceptable alternatives among the controversial parties of scholastic Calvinism that their denial could be considered characteristic of anti-Calvinism and, accordingly, in opposition to the mandatory theology of the state church.

Suspected of political (republican) motivation, the Remonstrant Arminians were attacked by Prince Maurice and later were condemned by the Synod of Dort. Many were banished, some adhered to the Roman Catholic Church, and others were persecuted. By 1630, the Dutch Remonstrants were legally tolerated. It was not, however, until 1795 that the Remonstrant Brotherhood was officially recognized. This movement continues to assert effective liberalizing tendencies in Dutch Protestant theology. (*See* also Netherlands, The: *History*; Oldenbarnevelt, Johan van.)

In England, in the 17th century, Arminianism was a term used by opponents to denigrate the Laudian theories of episcopacy and church discipline, though this movement was only slightly, if at all, influenced by the work of Arminius. The latitudinarians of Oxford and Cambridge likewise were called Arminians, though their rationalism was admittedly a revival of Platonism (*see* Cambridge Platonists).

In the 18th century the Wesleyan movement was at first distinguished from the revivalism of George Whitefield by the phrase "Methodist Arminianism." Later John Wesley accepted the term in the title given to the publication he edited from its first issue,

Jan. 1, 1778, to the time of his death. *The Arminian Magazine* would maintain, he wrote, "that God willeth all men to be saved, by speaking the truth in love." Wesley went to Amsterdam, Neth. (Nov. 1777), and secured the data for the article on the life of Arminius that was published in the first issue. He concluded that Arminius was "a person with whom those, who mention his name with the utmost indignity, are quite commonly unacquainted." Accordingly, Wesley initiated a reappraisal of the theology of Arminius based on that author's works and sharply distinguished from the "Arminianism" of the rationalistic Remonstrants of Holland as well as the "Arminianism" of England in the preceding century.

The Wesleyan revival of the study of Arminius' theology was a major factor in the coherent development of Methodist doctrinal affirmations in Great Britain. In the United States, Methodist theology as articulated by systematic theologians in the theological schools (1845–85), contrariwise, failed to follow Wesley's concern for the study of the works of Arminius and reverted to the Remonstrant theology of Philipp van Limborch and Simon Episcopius. Hence American Methodist "Arminianism" has never been rooted in the basic affirmations of Arminius. This fact accounts, in some measure, for the theological disparities between British Methodist theology and that of 19th-century American Methodism.

Jonathan Edwards' critique of New England Arminianism in the 18th century attacked positions that had little in common with the theology of Arminius. New England Arminianism indicated a theological ferment uniquely relevant to the new world as distinct from Britain and the continent.

In later times the renascence of Calvinism under the influence of Karl Barth, as well as expanded studies of John Calvin and the cultural, social and political influences of Calvinism in history, occasioned revived interest in Arminius and re-evaluations of Arminianism.

ARMINIUS (18 B.C.?–A.D. 19), German leader who inflicted a major defeat on Rome by destroying three legions in the battle of the Teutoburg Forest (*q.v.*). He was a chief of the Cherusci (*q.v.*), and in Roman service had obtained both citizenship (perhaps as C. Julius Arminius) and even equestrian rank. The circumstances of the rising of A.D. 9 are unknown, but the attack on the Roman general Quintilius Varus as he left his summer camp was cleverly organized and Roman power east of the Rhine was abruptly broken. In A.D. 15 Germanicus Caesar (*q.v.*) engaged Arminius again, taking advantage of the latter's quarrel with his father-in-law, Segestes. Arminius' wife, Thusnelda, was captured, but the next year he survived a full-scale Roman attack with considerable credit. When Roman operations were suspended in A.D. 17, Arminius became involved in war with Maroboduus, king of the Marcomanni, and, although successful, was subsequently murdered by his own people.

The conception of Arminius as a German national hero, which reached its climax in the late 19th century, can claim support from Tacitus' judgment of him as "unquestionably the liberator of Germany" (*liberator haud dubie Germaniae*); and it is clear that Augustus' plans for the country between the Rhine and Elbe rivers, though their exact nature is uncertain, were severely checked in A.D. 9. Yet Arminius was leader of a single tribe, and in his day a united "Germany" was not even an ideal. His greatness lay in his obvious ability as a military commander, and he is a most interesting example of the "Romanized" native chieftain at a very early period of the empire.

ARMINIUS, JACOBUS (JACOB HARMENSEN or HERMANSZ) (1560–1609), Dutch theologian and founder of Arminianism, was born in Oudewater, Holland, Oct. 10, 1560. His evocative writings and public disputations occasioned a long controversy in the scholastic Calvinism of his era over divine sovereignty and human freedom. Calvinist polemics long was arrayed against the theological position associated, erroneously, with his name. His father died when Arminius was an infant and Theodore Aemilius adopted the child and provided for his schooling in Utrecht. Upon the death of Aemilius in 1575, Rudolf Snellius (Snel van Roijen, 1546–1613), a professor at Marburg and a native of Oudewater, became the patron for his further education at the Universities of Leiden (1576–82), Basel and Geneva (1582–86). After some time in Rome he returned to Amsterdam where he was ordained in 1588. In 1603 he was called to a theological professorship at Leiden, which he held until his death, Oct. 19, 1609.

Arminius was a man of mild and liberal spirit, averse to coerced uniformity. The uncongenial controversies forced upon him involved his critical denial of the stern Dutch Calvinist scholasticism, which affirmed a supralapsarian decree of predestination; *i.e.*, the divine decree determining the elect was effected prior to the Adamic fall. Consequently, human decision was asserted to be wholly irrelevant even as a secondarily causal factor in salvation. Arminius asseverated a conditional election in which the divine proffer of salvation might or might not be accepted by a validly free will.

After his death the theological movement associated with his name developed a rationalistically systematized theology that eschewed many of his convictions and organized the Remonstrant Brotherhood in Holland. (*See* also ARMINIANISM.)

The works of Arminius (in Latin) were published in a single quarto volume at Leiden in 1629, and at Frankfurt in 1631 and 1635. Two volumes of an English translation, with copious notes, by James Nichols, were published at London, 1825–28; three volumes (complete) at Buffalo, N.Y., 1853.

BIBLIOGRAPHY.—A life was written by Caspar Brandt, son of Gerard Brandt, the historian of the Dutch Reformation, and published in 1724; republished and annotated by J. L. Mosheim in 1725; and translated into English by John Guthrie in 1854. James Nichols also wrote a life (1843). (DA. C. S.)

ARMISTICE, an agreement for the general cessation of active hostilities between two or more belligerents. Distinguished from general armistices are arrangements for a short-term or partial suspension of arms called local armistice or truce which may be made between commanders in the field, for a variety of purposes such as burying the dead. General armistices are made by commanders in chief, usually pursuant to political decision of the governments concerned. An armistice does not put an end to the state of war. Unless the agreement provides otherwise, belligerents may continue to exercise rights of war such as blockade, visit and search, and seizure of contraband. Armistices, whether for a fixed or indefinite term, are considered temporary, leading to final peace or resumption of hostilities. According to the 1907 Hague convention respecting the laws and customs of war on land, any serious violation gave the other party the right to denounce the armistice or to resume hostilities.

World Wars I and II.—The scope and function of armistices have undergone a significant evolution since World War I. The armistice agreement of Nov. 11, 1918, with Germany, was preceded by negotiations between the belligerents resulting in a so-called "pre-armistice" agreement. The Armistice departed from the usual form also in including political and financial clauses in addition to the military terms. Furthermore, the latter made the resumption of hostilities virtually impossible for Germany. The policy of unconditional surrender adopted by the United Nations during World War II changed the pattern of armistice agreements. The "Conditions of an Armistice" presented by the commander in chief of the Allied forces, Gen. Dwight D. Eisenhower, were accepted on Sept. 3, 1943, by Marshal Pietro Badoglio as head of the Italian government. An "Act of Military Surrender" was signed by representatives of the German high command at Reims on May 7, 1945, and at Berlin on May 8, 1945, whereby they were to "surrender unconditionally to the Supreme Commander, Allied

Expeditionary Force and simultaneously to the Soviet High Command all forces on land, sea, and in the air . . . ." Hostilities in the Pacific ceased on Aug. 14, 1945, when Japan accepted the terms of the Potsdam declaration of July 26, 1945. A formal "Instrument of Surrender" was signed on Sept. 2, 1945, on board the U.S.S. "Missouri," by representatives of the emperor of Japan, the Japanese government and the Japanese imperial general headquarters. In it they proclaimed "the unconditional surrender to the Allied Powers of the Japanese Imperial General Headquarters and of all Japanese armed forces and all armed forces under Japanese control wherever situated." The instrument also declared that, "the authority of the Emperor and the Japanese Government to rule the state shall be subject to the Supreme Commander for the Allied Powers . . . ."

It is clear that the unconditional surrender of the opponent rules out any possibility of resuming hostilities. The juridical difference between the instruments imposed upon and accepted by Italy, Germany and Japan and the traditional armistice is to be found in the absence of any limitation on the freedom of action of the victor save such restriction as resulted, in the case of Japan, from the presurrender agreement constituted by the offer and acceptance of the terms of the Potsdam declaration. Still, juridically, even unconditional surrender does not end the state of war between the parties.

After World War II.—The Security council of the United Nations (UN) had on several occasions called for a cease fire or truce during the hostilities in Indonesia, 1947–48, Palestine, 1948, Kashmir, 1948, and Korea, 1950. In all cases but one, armistice or truce agreements were signed by the parties. The exception was Kashmir where, formally, a cease-fire agreement of Jan. 1, 1949, was signed by India and Pakistan. The truce ("Renville") agreement of Jan. 17, 1948, between the Netherlands and the Republic of Indonesia was of short duration, hostilities having been resumed by the Netherlands on the ground of alleged violations of the truce terms by the republic. In Palestine separate armistice agreements were entered into in 1949, by Israel, on the one hand, and Egypt, Syria, Lebanon and Jordan, on the other. An elaborate system of demarcation lines, demilitarized zones and supervisory agencies (the United Nations Truce Supervision organization and several Mixed Armistice commissions) characterized these agreements.

In accordance with traditional international law regarding armistice agreements, Egypt claimed the right to stop, visit and search for contraband ships passing through the Suez canal and the Gulf of Aqaba and carrying cargo to and from Israel. Israel protested, arguing that the armistice agreements were *sui generis* (unique) and excluded all acts of hostility, as did the UN charter. The Security council, by a resolution adopted unanimously on Sept. 1, 1951, called upon Egypt to terminate interference with shipping and declared that "neither party can reasonably assert that it is actively a belligerent or requires to exercise the right of visit, search and seizure for any legitimate purpose of self-defense." In declaring further that the armistices contemplated "the return to permanent peace in Palestine" the Security council rejected for members of the UN the traditional concept of armistice which permits, legally, a return to active hostilities. The United Nations acted on this theory after the outbreak of hostilities in the Sinai peninsula between Egypt and Israel on Oct. 29, 1956. The agencies mentioned above were charged to supervise the armistice regime and handle complaints subject to the authority of the Security council. This regime was substantially strengthened in 1956 by the stationing, pursuant to general assembly resolution of Nov. 7, 1956, of the United Nations Emergency force on the Egyptian side of the demarcation line with Israel.

Hostilities in Korea were brought to an end formally by the Panmunjom armistice agreement of July 27, 1953, between the commander in chief, United Nations command, on the one hand, and the supreme commander of the Korean People's army and the commander of the Chinese People's Volunteer army, on the other. It provided for "a complete cessation of hostilities and of all acts of armed force. . . ." A demilitarized zone, a Military Armistice commission and a Neutral Nations Supervisory commission (Sweden and Switzerland for the United Nations command; Poland and Czechoslovakia for the other side) were established. The latter commission ceased to function as it was denied free movement to investigate the implementation of the armistice on the North Korean side. Unlike the traditional armistice, this agreement excluded a legal return to active hostilities. Under sec. 62 it was to remain in effect "until expressly superseded . . . by provision in an appropriate agreement for a peaceful settlement at a political level between both sides." Sec. 13-d prohibited any reinforcement of the forces in Korea. In view of the vast build-up of forces in North Korea in violation of this section of the armistice agreement, the United Nations command announced on June 21, 1957, that it would modernize the United Nations forces in order to restore the balance which the agreement was intended to preserve.

The conflict in French Indochina was terminated by the Geneva "Agreement on the Cessation of Hostilities in Viet-Nam" of July 20, 1954, between the commanders in chief respectively of the French Union forces in Indochina and the People's Army of Vietnam. A demilitarized zone and an international commission (Canada, India, Poland) were set up. This agreement did not refer to an "armistice" as the hostilities were not of international character and, therefore, not war in the technical sense of the term. Moreover, a resumption of hostilities was not excluded as according to art. 1, the demilitarized zone was "to act as a buffer zone and avoid any incidents which might result in the resumption of hostilities." However, the emergence of several states in the area (Laos, Cambodia, North Vietnam and South Vietnam) deprived this clause of practical significance.

Compared with the purely military function of the traditional armistice, the later practice indicates a growing political significance. Some of the later armistices (Palestine, Korea) operated as, admittedly unsatisfactory, substitutes for formal peace treaties. Although technically a state of war subsisted, hostilities definitely stopped. Resumption of hostilities, even as a matter of formal right, under international law, was excluded by virtue of the charter of the United Nations. The charter prohibits resort to force or threat of force, except in self-defense against armed attack, and a resumption of hostilities would come under this prohibition.

ARMISTICE DAY: *see* Veterans Day.

ARMORICA (Aremorica), the Latin name for the northwestern extremities of Gaul (*q.v.*), derived from two Celtic words, *ar*, "on," and *mor*, "sea." In Celtic, Roman and early Frankish times Armorica comprised not only the later Brittany but also the western part of what was afterward Normandy. In Julius Caesar's time it contained five principal tribes, the most important being the Veneti (*q.v.*). Under the Roman empire it formed part of the province of Gallia Lugdunensis but was never thoroughly romanized. From the second half of the 5th century Armorica received many Celtic immigrants from the British Isles. *See* Brittany.

ARMOUR, the name of a family of U.S. businessmen who helped to create a new industry in meat packing. Philip Danforth Armour (1832–1901) entered the grain and pork-packing business in 1863 with his brother Herman Ossian Armour (1837–1901) and John Plankington. In 1870 Armour and Company was formed as a family partnership of Philip D., Herman O. and Andrew Watson Armour (1829–92). Philip D. served as president from 1875 to 1901 and was responsible for introducing new methods for utilizing waste products and employing refrigeration. He founded the Armour Institute of Technology at Chicago in 1892. His son Jonathan Ogden Armour (1863–1927) became president at his father's death. Under his leadership the business continued to prosper and expanded into new fields. When J. Ogden retired in 1923 the company was the largest meat-packing firm in the world. Grandsons of Philip D. and Andrew Watson served on Armour and Company's board of directors after J.

Ogden's retirement, but the direct control did not remain in the family.

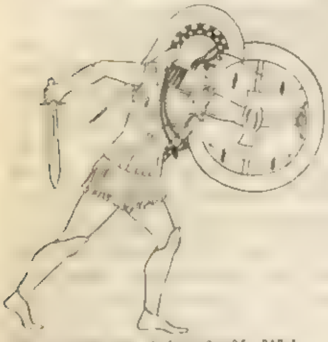
ARMOUR, BODY. In Homeric and Hellenistic times, bronze was the metal most frequently used for body armour. The armour of the Greeks of historic times and of the Etruscans was highly developed, the forms and outlines pleasing to the eye and the surfaces embossed, engraved and sometimes inlaid with precious metals. The head was protected by a bronze helmet (*q.v.*), often with a dyed horsehair crest supported on a high semicircular plume holder. The body was protected by a bronze cuirass, often modeled to the muscles, and breast- and backplate were joined over the shoulders with braces. A large circular or kidney-shaped shield with a bronze covering was carried in the left hand. The thighs were loosely protected by labels hanging from the cuirass, arms and knees were left bare for the sake of easy movement and the shins were protected by bronze greaves shaped to the leg. The organized armies of the Roman empire were given standardized equipment. The arming of an officer and centurion, who often wore a solid cuirass, was more elaborate than that of the legionary, who was given a round iron helmet (*cassis*) and a cuirass (lorica), which in imperial times consisted of hoops of metal or leather around the body, joined by similar hoops passing over the shoulders. The shield was rectangular and curved to the body. The principal weapons of the legionary were the throwing spear (pilum) and a short sword. The ax sometimes took the form of a *bipennis* (two-edged), which was part of the lictor's insignia. (*See* also Weapons, Primitive.)



FROM AN ATTIC VASE IN THE LOUVRE, PARIS

FIG. 1.—GREEK SOLDIER (HOPLITE), 5TH CENTURY B.C.

A very important development in body armour was the introduction of garments composed of interlinked metal rings, known as mail. Mail is found on Roman sites throughout the empire covering a long period of time. It is clearly represented in Roman art, but its use seems to have been limited. It is generally thought that mail was not indigenous to the empire but was introduced from outside. Mail falls into two classes. In one the rings are secured, either by each link having its ends riveted together or by alternate links of solid, punched rings joined by riveted rings; in the other the rings have their ends butted together. The latter is much weaker than the former and there is a notable division between west and east—*i.e.*, Europe and Asia—in that western mail was almost always riveted and oriental mail more often constructed of butted rings. Scale armour was also used by the Romans.

FROM THE COLUMN OF MARCUS AURELIUS, ROME

FIG. 2.—ROMAN LEGIONARY, 2ND CENTURY A.D.

Besides defensive armour made of metal plates and of mail, there are other categories that can be regarded as substitutes; one is padded armour, consisting of a linen shirt padded with tow and quilted, which was much cheaper and easier to make than mail. It was often worn as an undergarment with mail to deaden the effects of blows that would otherwise badly bruise the body. Such padding was used with Sudanese mail as late as the battle of Omdurman in 1898. Various alternatives were tried, especially in 14th-century Europe when mail was being superseded once more by plate armour and the two were often worn together; the resulting weight sent man looking for substitutes for metal. Horn and boiled leather (called *cuir bouilli* in Norman-French) were tried. Among primitive peoples there were attempts to make armour of wooden slats strung together, and among the Micronesians of the Kingsmill group (Gilbert Islands), even of plaited rope.

FIG. 3.—ENGLISH INFANTRY AND NORMAN CAVALRY AT THE BATTLE OF HASTINGS, 1066

In the early middle ages in Europe, combatants, especially mounted ones more able to carry the weight, wore helmets of iron usually with a nasal (nose guard), mail shirts reaching to the knee and with short wide sleeves, and carried shields. Armour of the period is extremely rare because of the cessation of the pagan custom of burying arms with the dead.

FIG. 4.—MOUNTED KNIGHTS OF ABOUT 1280

Mail continued to be the main defense of the body and limbs during the 12th and 13th centuries. The sleeves of the hauberk were lengthened and a hood of mail covered the head and neck. Leggings of mail were more freely used than previously. At the end of the 12th century the great cylindrical helm was introduced, and in the course of the century the shield was shortened and made straight across the top, forming a triangle with curved sides. Under the feudal system a personal and hereditary form of heraldry was developed which was freely used to decorate the shield and the linen surcoat (which after about 1200 was worn over the mail shirt), the textile trapper of the horse and, in fact, any other surface or detail of equipment on which it could be applied (*see* Heraldry). The medieval knight on his horse was a highly picturesque and brightly coloured figure. Mail, however, had its disadvantages. It did not possess the rigid, glancing surface of plate armour, and as soon as this could be made responsive to the movement of the body by ingenious construction, it replaced mail, except as a subsidiary. Plate armour of iron and steel required great skill in the making and became the specialized product of certain cities (*see* below). Similarly, the making of swords became largely concentrated in such places as Passau and Solingen in Germany, and later Toledo in Spain. The wearing of fine armour marked out the squire or the knight, to whom the only profession open was military service. The common soldiers had to wear what they could afford or pick up on the battlefield and, being footmen, they could not carry too great a

[illegible] Their equipment generally comprised [illegible] cap, a shield and a sword and [illegible] a shirt of mail or a brigandine, [illegible] was a form of scale armour made [illegible] plates of metal riveted inside [illegible] of textile. The brigandine, because of its flexibility, was a useful substitute for the solid cuirass.

The history of body armour is the record of continual rivalry between weapons of [illegible] and of defense. For each new [illegible] that was introduced or improved [illegible] defense had to be found. The [illegible] horseman became a victim to [illegible] skill in archery, in which the English excelled. The size of horses made them especially vulnerable, and they had to be armoured, at first with mail trappers and later with plate comprising a chamfron for the head, crinet for the neck, poitrel for the chest and crupper for the hindquarters. The great victories won by Edward III the Black Prince and Henry V in the Hundred Years' War (1338–1453) were largely the result of the expert skill of the English bowmen. They wielded the longbow (from five to six feet in height, [illegible] for which both muscular strength and long training were needed to secure proficiency. The English archers shot so fast and with such accuracy that their fire resembled that of the machine gun of later days and their opponents could not come within hand strokes.

FIG. 5.—KNIGHT WEARING ARMOUR OF MIXED MAIL AND PLATE, ABOUT 1340

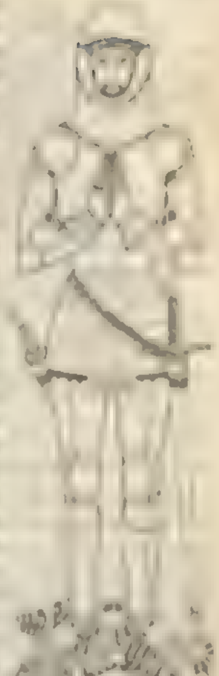
[illegible] the 14th century mail was gradually superseded by plate armour of steel, at first by local additions to knees, elbows and shins, until eventually the complete covering of articulated plates was evolved. In the second half of the 14th century the long surcoat was replaced by the short, tight-fitting gipon or jupon and the shield was discarded for war. Great skill and knowledge were lavished on making plate armour flexible by means of overlapping pieces held together on the inside by leather straps. The great helm was replaced by the lighter basinet with movable [illegible] in the 14th century. This was followed by the sallet [illegible] in the next century. [illegible]

Complete plate armour of steel, called "all-white" armour, of the 15th century followed the lines of the human body with subtle variations which make the armour known as that of the Gothic period so pleasing to the eye. It is so called because the forms of its decoration were [illegible] those of the style of architecture [illegible] name, with its points and cusps and [illegible] surfaces. It was especially favoured in Germany and was produced in Augsburg and Nurnberg in the second [illegible] 15th century. At the same time the [illegible] of Milan produced armour of superb quality, the steel being of the finest temper, but the forms were smoother and more rounded. The defenses of the left or bridle arm were built up more [illegible] the [illegible] from these two sources, [illegible] was made by native craftsmen, as the existence of city guilds testifies. [illegible] attain the same [illegible] centres of south Germany [illegible]

FIG. 6.—MONUMENTAL BRASS OF JOHN CRAY, [illegible] 1390

The Gothic style was replaced early in the 16th century [illegible] protection.

Hard on the heels of full-plate armour came gunpowder (q.v.). Cannon appeared in [illegible] in the first half of the 14th century, but some [illegible] before their full effect was felt. [illegible] finest armour ever fashioned was made long after the introduction of gunpowder. The centres of Augsburg and Nurnberg produced families of artist-craftsmen, among them the Colmans, the Siebenburgers, Lochner [illegible] duced the M[illegible] and Piccinin[illegible] Henry VIII set up his [illegible] where [illegible] officer by its magnificence, it was [illegible] a convenient diplomatic gift. [illegible] armour to survive its [illegible] smooth surface of the [illegible] (early 16th century). The influence of the Renaissance in painting and sculpture affected the armourer's craft to a marked degree. Embossing tended to make armour a work of art rather than a useful [illegible] face, disappears when the finish is broken up by protuberances in the form of scenes of classical mythology and Medusa heads.



[illegible] ABOUT [illegible]

FIG. 7.—MONUMENTAL BRASS OF ROBERT LORD FERRERS OF CHARTLEY ABOUT 1410

Once firearms could be made in quantity, men trained in their [illegible] wreak havoc on the armed chivalry of Europe. In the course of the 16th century the armoured man gradually disappeared from the field and only the heavy cavalry or lancers remained for shock tactics. The centralized monarchies of the 16th [illegible] mustered trained armies with specialized corps, with mercenaries such as the *Landsknechts* (infantry), targeteers, pikemen and harquebusiers. (See ARMY, TACTICS.)

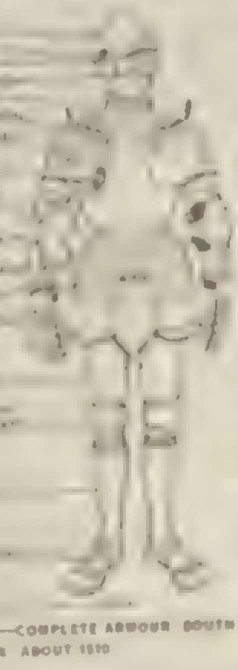


FIG. 8.—COMPLETE ARMOUR SOUTH GERMAN ABOUT 1510

When armour was falling into disuse, such substitutes as the jack (a form of brigandine) and later the buff coat (a garment of cowhide which could stop a sword slash) were worn. [illegible] wore half-armour and heavy cavalry during the first half of the 17th century wore three-quarter armour with long tasses and high boots. During the English Civil War of the 1640s the bulk of the infantry were pikemen who wore broad-brimmed helmets, breast- and backplates and square tasses on the thighs. Some of the cavalry wore cuirassier armour at the beginning of the war but quickly abandoned it. Most officers and mounted troopers wore steel helmets and a cuirass consisting of a breast-

AFTER JAKOB DE GHEYN, "EXERCISE OF ARMES FOR CALIVRES, MUSKETTES AND PIKES"

FIG. 9.—PIKEMAN, 1607

and backplate with a buff coat, and carried a brace of pistols and a broadsword. The lance was temporarily in abeyance until reintroduced from Poland in the 18th century. The musketeers or "shot" wore no armour and were equipped with broad-brimmed hats to shield their lighted matches.

Toward the end of the 17th century, armour increased in weight in order to remain effective against musket fire. At the same time, however, new strategy and tactics called for greater infantry mobility, and armour fell into general disuse and was not widely used again until World War I. (J. G. Mn.; X.)

Modern Armour.—The increased use of high-explosive artillery shells in World War I resulted in a high proportion of wounds caused by shell fragments. Steel helmets were designed, and after the first year of war, were worn by all troops. Torso armour of both fibre and steel was issued to troops for special purposes but was generally too heavy for full acceptance. In World War II, casualties from shell fragments rose to 80%, and, with 70% of all wounds affecting the torso, it became highly desirable to produce a suitable body armour. Armour for bomber crews and ground troops was developed of steel, aluminum, and resin-bonded fibre glass plates, as well as of heavy nylon cloth.

By the second half of the Korean War all U.S. combat troops were equipped with an effective body armour developed by the U.S. navy and marine corps. It consisted of a 10-lb. vest and a 4-lb. lower torso protector. For the flexible portions a 13-ply nylon cloth was used, while the vest had 22 5×5-in. overlapping plates of fibre glass cloth bonded by a thermosetting polyester resin.

After the Korean War the U.S. army developed $8\frac{1}{2}$-lb. vests that gave slightly less protection. One was made entirely of nylon cloth, the other of 3×3-in. titanium plates. In the war in Vietnam, both army and marine corps armour was used by U.S. combat troops. Crew members of low-flying aircraft wore a 25-lb. aluminum oxide ceramic breastplate that was effective against high-velocity bullets, and the U.S. navy developed a 4-lb. armour vest and buoyant life jacket made of a synthetic felt that entangled fragments. Efforts to produce better armour centred around protecting vulnerable portions of the body and developing stronger and lighter materials. Thus armour boots to deflect and absorb fragments and blast of mines were introduced, as well as flexible stainless steel inner soles for protection against steel and bamboo spikes. Also developed for armour applications were synthetic fibres of greater strength and harder but lighter ceramics, such as boron carbide. (F. B. Ni.)

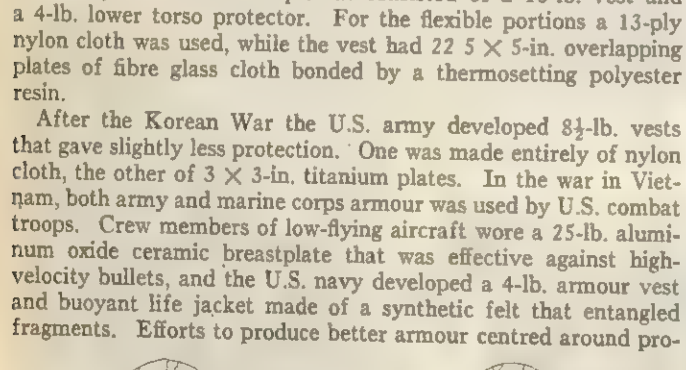

FIG. 10.—U.S. BODY ARMOUR, 1951–67

Other Countries.—The story of arms and armour outside Europe is a varied one. In the hot near eastern climate and in India, mail was preferred for its flexibility to complete armour of plate. Although plates were used for certain parts of the body, body armour of plate was never developed to the same extent as in Europe. Indo-Persian armour consisted as a rule of a helmet with nasal and three plumes, a coat of mail with four plates, front, back and sides, known as the "four mirrors," and short vambraces on the forearms, and a circular metal shield with four bosses. Rich ornamentation was lavished upon it, especially damascening with gold and silver. Changes of form were not as rapid as in the west. As a substitute for mail a padded garment faced with velvet and studded with rivets was worn, known as "the coat of the thousand eyes."

Japan produced a distinctive armour of its own which from time to time was influenced by contact with the west. (*See* JAPAN: *Defense.*) The helmet (*kabuto*) with its large neckguard was often given a most ferocious mask. The Japanese continued to wear armour until the modernization of the country in the third quarter of the 19th century. In 1908 the British army encountered mailed horsemen for the last time in the highlands of Tibet.

The arming of other peoples depended on the standard of their culture and the materials at hand as well as on climate and terrain. Whereas in the north of Africa mail was worn, as it was in Turkey Persia and India, the Kaffir of the south fought almost naked and carried only a large hide shield for his defense. His arms were the throwing spear (assagai) and club (knobkerrie) until he acquired flintlock "trade guns" of European export.

The North American Indian wore no armour, and his weapons were the spear, the bow and the tomahawk (ax). The Indians of Central America and Mexico had decorative breastplates of gold or silver, and the Aztecs of Mexico wore quilted cotton vests.

ARMOUR, NAVAL. The idea of giving extra protection to the hulls and decks of war vessels is a very ancient one. Archimedes, in building the famous "Syracusan"—that most palatial of ancient ships—for King Hieron about 250 B.C., provided for "mats composed of stout ropes suspended by brazen chains." No doubt these were a provision against ramming and missiles; and the a-

bles that were made taut around the hulls of Greek ships served at least in part the same purpose. The "Syracusan," too, was completely surrounded by an iron balustrade, but its vertical dimensions are unknown. In Rome there was an accepted technical distinction that divided all war vessels into *apertae* (with uncovered deck) and cataphracts such as the quinqueremes, in which the wall of the ship was raised beyond the main deck as a protection to the rowers. In Byzantine times, when combustible—and perhaps explosive—missiles came into use, leather curtains or saturated woolen sheaths were adopted. By the 11th century the Scandinavian sea kings had vessels that were armoured in the modern sense. There is mention of this in the *Svarfdaela:* "Ljot the Pale is in the east in the Swedish isles; he has . . . a 'dragon' covered with iron above the sea; it goes through every ship." There was another such vessel owned by Fridthjof's father, Thorstein, "and its sides were sheathed with iron" (*Fridthjof's saga I*). The iron bands over the prows of the medieval ram-ships are well known. A manuscript of about 1430 mentions a "covered" ship of that type as in use by Catalonians, a formidable ship that has also been mentioned in other historical documents.

Until the close of the Napoleonic wars ships of the line were virtually armoured, for their sides of almost two feet of oak were nearly shotproof to naval artillery of the day at all but short ranges. The increase and more effective use of gunpowder toward the middle of the 19th century made metal armour indispensable.

Historically, the earliest of modern proposals to employ armour for ships of war appears to have been made in England by Sir William Congreve in 1805. In the *Times* (London) of Feb. 20 of that year, reference is made to Congreve's designs for an armoured floating mortar battery that the inventor considered to be proof against artillery fire. Among Congreve's unpublished papers there is also a suggestion for armour plating the embrasures of casemates. Nothing, however, seems to have come of these proposals, and a similar lack of appreciation befell the next advocate of armour, John Stevens of Hoboken, N.J., who submitted the plans of an armoured vessel to the U.S. congress in 1812. The Stevens family, however, continued to work at the subject, and by 1841 had determined by actual experiment the thickness of wrought-iron armour that was proof against the projectiles then in use.

In 1827 a proposal to apply iron for defensive purposes was put forward by Major General Ford of the royal engineers who suggested iron bars as a protection for the face of masonry in forts, but the result of the experiment was not encouraging. In 1840 experiments were conducted by the British admiralty to ascertain the effect of shot on iron plates backed with various soft and elastic substances. These experiments were instituted not so much for the purpose of testing the value of defensive armour against shot but to ascertain the value of iron as a material of construction for ships of war. The employment of thick iron plates as an external casing for the protection appears first to have been carried out by the French, who in the Crimean War employed three iron-cased floating batteries in the attack upon Kinburn fortress on Oct. 17, 1855. These batteries, one of which was appropriately named the "Congreve," were exposed to a heavy fire at a distance of 700 yd. for about three hours, unsupported by the fleet, and although some casualties occurred from shell and shot entering the large old-fashioned portholes the floating batteries themselves were practically undamaged. Early in the American Civil War the value of protective armour was again conclusively proved in the battle, March 9, 1862, between the "Monitor" and the "Merrimack," both armoured vessels. (*See* "MONITOR" AND "MERRIMACK," BATTLE OF.) In the Civil War, railroad iron was sometimes used for side armour, and turret armour was built up of laminated one-inch plates. Thenceforth the utility of iron armour in protecting ships of war became apparent, and this article describes below the successive steps by which modern armour has been evolved.

In 1857 experiments were made at Woolwich, Eng., with a set of four-inch iron and steel plates, and it was found that in some cases the plates offered good resistance at 600 yd. to 68-pounder solid shot, but that with a repetition of blows the plates were broken up. Wrought-iron shot appeared much more destructive than cast-iron shot, and as a defensive material steel plates were far inferior to wrought iron in point of resistance. Tests were also made on the resistance of cast-iron blocks. These blocks were 8 ft. long, 2 ft. broad and 2½ ft. thick, fitted together by tongues and grooves. They were fired at from a 68-pounder with cast-iron solid shot, and wherever the shots struck, radiating cracks were formed, sometimes extending through the block. A greater effect was produced with wrought-iron shot which recoiled unbroken, whereas the cast-iron shot always broke up.

For the purpose of investigating thoroughly the application of iron to defensive purposes of war, a special committee on iron was appointed in 1861 by the British secretary of state for war with the concurrence of the admiralty. This committee sat until 1864 and conducted a large series of investigations and experiments.

The committee came to the conclusion that a steel material, either alone or in combination with iron, was unsuitable, and the most practical material was simple wrought iron, which at its best combined in the greatest degree the qualities of softness and toughness. In order to allow the energy of the shot to be absorbed in indenting and battering the plates without producing further fracture, rolled iron plates were on the whole found to be better than hammered plates, as hammered plates generally had the tendency to be hard and unequal, though at the same time rolled plates were frequently affected by unsound welding.

Great interest had always been given to the question of which backing was most suitable for ship armour plates. When armour plates were first used they were fixed directly upon the hull of timber ships, and when first applied to iron ships it was thought expedient to imitate the former condition by placing a backing of wood between the armour plate and the hull of the vessel. Many objections were raised to this, among them being the liability of the wood to decay and to destruction by fire and shells, but the committee was unable to recommend that wood backing could be dispensed with, as it appeared to perform important functions for which no good substitute could be found. The wood backing was finally thinned down until its use was confined to fairing the surface of the ship so that the armour could be really fitted to it.

Iron Armour.—The earliest armour was therefore made of wrought iron using both rolled and hammered plates. The French ship "Gloire," a wooden frigate protected by a complete belt of iron armour 4¾ in. in thickness, completed in 1859, was the first armour-clad ship of war. The British ship "Warrior," completed in 1861, was the first armour-clad warship to be built entirely of iron, the armour belt consisting of iron armour 4½ in. thick. Laminated wrought iron was used on American vessels during the Civil War, since there were no facilities available at that time in the United States capable of producing single plates of the required thickness. The increase in calibre of guns and the use of steel shot necessitated an increase in thickness of armour, and on the "Bellerophon," completed in 1866, a thickness of six inches of armour was fitted. The introduction of Palliser's ogive-pointed chilled-iron shot and further improvements in size and penetrative power of naval ordnance were met by further increases in thickness of armour, resulting in the "Inflexible," completed in 1881, carrying a belt 24 in. thick, worked in two layers of 12 in. each.

It was becoming increasingly clear that some way had to be found to give armour a very hard face with a tough back. Several proposals to weld or cement steel plates to wrought iron were made between 1860 and 1870, but none succeeded since techniques were needed that were beyond the capacity of the metallurgists at the time. Interest then shifted to steel plate as a result of the development of the Bessemer process of making steel in a converter and the Siemens-Martin open-hearth process of producing steel.

Steel Armour.—The superiority of steel armour was clearly demonstrated in 1876, when a 22-in. mild steel plate made by the French firm Schneider et Cie defeated projectiles from the largest guns then in use in a trial at La Spezia, Italy. This plate was forged from open-hearth steel, and although it had greater resistance to penetration it showed more of a tendency to crack and break up, particularly with repeated blows. This fault led to renewed interest in built-up or compound armour which consisted of a steel face backed with wrought iron.

Compound Armour.—The first satisfactory compound armour

plates were introduced by the two Sheffield firms, Cammell and Brown, the processes being known as the Wilson-Cammell and the Ellis-Brown respectively. In the Wilson-Cammell process a wrought-iron plate, while red hot, was placed in a mold, and liquid steel was poured on top. As the temperature of the liquid steel was much in excess of the welding heat of iron, the surface of the iron plate became partially fused by the liquid steel, and thus a complete union between the two metals was obtained. In this case, the weld was not limited to a simple line of junction between the iron and steel, but the change from iron to steel was gradual. When the steel became solid, the plate was removed from the mold, and after reheating was rolled down to the thickness required. At the La Spezia trial in 1882, Cammell's plate was rolled down from a thickness of 30 in. to 18.9 in., the final hard-steel face being about 6 in.

In the Ellis-Brown process, a steel plate for the face and a wrought-iron plate for the back were united by running molten steel between them, the combined plate being subsequently rolled down to the correct thickness. In Brown's 18.9-in. plate also tested at La Spezia the final hard face was about 3 in. thick, the total thickness of steel being about 6 in. As a result of these trials, a proportion of about one-third steel and two-thirds iron was found to give the best results.

Compound armour was first used on the turrets of the "Inflexible" and continued in general use in the British navy up to the "Royal Sovereign" class (1892). In this class of ships the belt was of compound armour 18 in. thick. The superiority of compound armour over iron was computed to be in the proportion of about three to two.

The introduction about 1886 of the Holtzer and other forged steel armour-piercing shot, which could not be shattered as the Palliser shot had been, presented fresh problems. The compound plate relied upon breaking up the shot, but if the shot pierced the hard face without breaking up, the soft iron back could not offer much resistance.

The attention of makers who favoured compound armour was thus directed to the necessity of increasing the hardness of the steel face, and in 1887 Capt. T. J. Tresidder patented a method of rapidly chilling the steel face by means of jets of water under pressure. From 1882 to 1890 several international trials took place at which various makes of compound and all-steel armour were tested, and although compound armour was generally adopted in Great Britain, yet in Europe the superiority of this armour over all-steel armour was not universally acknowledged, and French ships of this period were protected by steel and compound armour in about equal proportions.

Nickel-Steel Armour.—A further advance was made by the French firm of Schneider in 1889, when nickel was added in the manufacture of all-steel armour to increase its strength and toughness. A gain of approximately 5% in the resistance of armour was achieved by using about 4% nickel. The manufacture of armour was begun in the United States about this time, by the Bethlehem Iron company and the Carnegie Steel company under Schneider patents, to provide nickel-steel armour for the battleships "Texas," "Maine" and "Oregon." The success of nickel-steel armour caused the elimination of compound armour as a competitor, and interest then centred on better methods of achieving a hard face and tough back in a single heavy plate.

Harvey Armour.—The next important improvement was the introduction in 1891 of Harvey armour. H. A. Harvey, a U.S. metallurgist who had obtained considerable success in water-hardening cemented steel in the case of small articles, turned his attention to the manufacture of armour plates by the same process. The method consisted in carburizing or cementing the face of a steel armour plate by keeping it at a high temperature in contact with finely divided charcoal, so that the heated surface absorbed a certain amount of carbon, which penetrated about one inch. After cementation, the plate was allowed to cool to a dull red heat and was then chilled by the application of water, but by a less perfect method than that employed by Tresidder. Steel plates treated by the Harvey and Tresidder processes combined possessed nearly twice the resisting power of wrought iron, and about one and a half times the resisting power of the former steel armour and compound armour. The best American results had been obtained with Harveyized nickel steel, but there was considerable difference of opinion about the value of introducing nickel, and its adoption was not universal in England. Harveyized armour was first used in the British navy in the "Renown," laid down in 1893, where the belt armour was ten inches thick

Krupp Armour.—The basic invention in all modern armour was Harvey's method of carburizing the front face of the plate, but the back of the plate was not sufficiently tough, and, after various experiments with steel of different composition, Krupp, of Germany, produced Krupp cemented plate in 1894, based on Harvey's invention. This was a nickel-chrome alloy. The addition of chromium permitted the carburization to extend deeper into the armour plate and increased the toughness of the entire plate. The outstanding development in Krupp cemented plate was the introduction of decremental face hardening. This consisted in heating the carburized face to a temperature sufficient to produce a glass-hard surface when water-quenched, at the same time keeping the back to a much lower temperature, in order to produce a tough and fibrous back. Both face and back were water-quenched simultaneously. This process, with slight variations, is usually adopted in modern armour making. Krupp cemented plates gave results that indicated they were equal to wrought-iron plates of nearly two and a half times their thickness. Krupp armour was first fitted in the "Canopus" class laid down in 1896 and to U.S. warships in 1900. The Krupp method of decremental hardening was also applied to thinner plates that were not carburized. These were known as Krupp noncemented plates. The manufacture of cemented armour is a specialized process, involving great care in the selection of materials and the subsequent casting and heat treatments. The details of composition and manufacture vary to some extent among different makers, but an average composition is 0.35% to 0.5% carbon, 3.5% to 4% nickel, 1.5% to 2.5% chromium, 0.4% manganese and 0.15% silicon.

Deck Armour.—During World War I naval engagements first occurred at long ranges with the consequent result that the deck

of naval ships had to be protected against plunging fire of heavy guns. The increasing threat of aircraft attack further emphasized the need for deck armour. The attack from heavy projectiles striking at oblique angles could best be resisted by an armour having great strength and toughness that would be capable of suffering considerable deformation without rupture and thereby deflect the projectile. This armour should also be capable of detonating aircraft bombs and, when fitted on more than one deck level, should prevent or restrict the entry of bomb splinters into the vitals of the ship. A hard, brittle, face-hardened armour similar to Krupp armour would be unsuited for this purpose, since it would tend to crack before the attacking projectile was deflected.

A noncemented armour was developed in the form of a nickel-chrome alloy, the composition of which varies with different manufacturers. Its ballistic properties result from the heat treatment to which the plate is subjected during manufacture. Specimens subjected to tensile tests have shown ultimate tensile strength as much as 120,000 lb. per square inch with an elongation in two inches of 23%.

Beginning in World War I, with renewed emphasis in World War II and the Korean war, light armour was developed to resist penetration of machine-gun bullets and aircraft bomb splinters. The plate had to be sufficiently soft in the untreated condition to permit machining, and hard enough after treatment to resist perforation by bullets or bomb fragments. Although strength was important, the necessity for good ductility was predominate. Various alloys, including nickel, chromium, cobalt, manganese and vanadium, have been tested, but a nickel-chrome alloy has given the best results. (W. J. B.; R. W. McN.)

In face of the added danger to the crews of minor war vessels and merchant ships caused by aircraft machine-gun fire and bombing in World War II, it became virtually impossible to meet the extra demands for steel armour plates. The "plastic armour" then developed in Britain was a valuable substitute and saved many lives. It was made of bitumen incorporated with granite chips and cast as slabs in light steel casings; it was proof against bullets and splinters. These slabs of plastic armour were widely used for protecting the bridges and exposed positions in landing craft, auxiliary war vessels and merchant ships.

Formulas for predicting or assessing the penetration of steel armour by projectiles ordinarily take into account the thickness of the armour, the striking velocity, weight and calibre (diameter) of the projectile, and the angle of impact. Such formulas may be used to furnish a rough comparison of performance between projectiles and plates of varying dimensions, provided the factors involved do not differ too widely. (X.)

ARMOUR, TANK AND AIRCRAFT, consists of any material intended to protect men, installations and equipment from attack by missiles and other weapons intended for their destruction. Although the history of the development and employment of armour extends back beyond recorded times, the modern use of armour dates from the mid-19th century when wrought-iron plates were fastened to the sides of floating batteries and warships in the Crimean and American Civil wars. (*See* ARMOUR, NAVAL.) The use of armour to protect soldiers had been practically abandoned by the 18th century but underwent a rebirth during World War I. (*See* ARMOUR, BODY.)

Tank Armour.—To overcome the static battlefield situations of World War I caused by the supremacy of antipersonnel weapons, the British introduced the tank in 1916, and first employed this new weapon in the battle of the Somme. (*See* TANK.) The early tanks were caterpillar-tracked boxlike vehicles whose crews were protected from machine-gun fire and shell fragments by steel armour plates from three-eighths to three-fourths of an inch in thickness. The advent of tanks led to the development of special antitank guns and armour-piercing projectiles, the latter consisting of solid steel shot with sharp pointed noses heat-treated to very high hardnesses to improve their armour penetrability. During World War I and up to a few years before World War II, armour-piercing projectiles were generally of small size, ranging from 7.6 mm. to 37 mm. (.30 in. to $1\frac{1}{2}$ in.). During World War II tank armour increased in thickness to 6 in., and armour-piercing ammunition in calibre to 155 mm. (6 in.), although by far the greater number of antitank guns were in the range of calibres from 50 mm. (2 in.) to 90 mm. (3.5 in.).

The material most commonly used as armour is heat-treated alloy steel, although many other materials, such as alloys of aluminum, magnesium and titanium and nonmetallic materials such as plastic laminates, nylon fabric, concrete and mastic-stone composites, have been and are being used in armour applications. Steel armour consists of two main types: homogeneous and face-hardened. Homogeneous steel armour is further subdivided into two classes—wrought or rolled armour and cast armour. Homogeneous armour possesses uniform chemical composition, mechanical and ballistic properties throughout its section thickness; face-hardened armour is specially processed to produce a very hard, penetration-resistant surface layer on the face exposed to attack, with a softer and tougher core to support the hardened case. The depth of the hardened layer may represent 10% to 40% of the total armour thickness and may be produced by a variety of means including carburization, which produces a high-carbon surface layer hardened to a high degree by heat-treatment. Other methods include flame hardening of one surface, a practice employed on German tank armour during 1940–43; nitriding (*q.v.*), which develops a thin, very hard surface layer by producing metallic nitrides (this practice was generally confined to thin aircraft armour); and duplex rolling, whereby a higher-carbon, higher-alloy steel is fused to a billet of lower-carbon, lower-alloy steel and then rolled to desired thicknesses and, upon heat-treatment, a hard face is developed on a softer, tough core.

Face-hardened steel armour was very effective against early types of armour-piercing projectiles since the noses of the projectiles shattered against the hardened surface, destroying their penetration effectiveness. It was discovered early in the 20th century that thick, face-hardened naval armour could be defeated by making the noses of armour-piercing projectiles blunter, and fitting them with soft steel caps which lessened the impact forces on the nose of the shot in the early stages of armour penetration. Steel-capped armour-piercing projectiles had, by the time of World War II, long been standard for naval use. Armour-piercing caps were applied during World War II first by the Germans, then quickly by the Allied armies, to antitank projectiles of all calibres. Capped armour-piercing projectiles quickly overcame the initial advantage of face-hardened armour, and since this type of armour was considerably more expensive and time consuming to manufacture and to fabricate into vehicles than homogeneous steel armour, its use in armoured vehicles was generally abandoned early in World War II.

Rolled armour is produced by casting large ingots, hot-rolling them down to slabs and billets and finally down to plates of desired thickness and size. Because of the large amount of hot-working, rolled armour generally possesses a fine-grained, uniform structure throughout and, in thinner sections at least, usually exhibits somewhat better mechanical and ballistic properties than cast armour. Very thick armour plates are usually wrought rather than rolled; *i.e.*, the ingots are heated and pressed between large flat dies until they are worked down to the required thickness.

Steel armour castings for tanks were first employed by the Germans in the early 1930s and were made in the U.S. by 1933. The first castings were relatively small, and were used as bolted attachments to cover protruding sections where riveted armour sections were excessively cumbersome to fabricate. With the tremendous expansion of tank production caused by World War II, there was insufficient production capacity to roll all the armour plate needed for armoured vehicles, and the steel castings industry was called upon to produce large shaped castings. By 1942 tens of thousands of tons per month of steel armour castings for tank turrets, hull front housings and other components were being produced in the U.S. alone. Although cast armour is somewhat inferior in ballistic performance to rolled armour in thicknesses under approximately $1\frac{1}{2}$ in., it is generally equivalent in protection performance at greater thicknesses. Since medium and heavy tanks during the latter years of World War II carried armour from two to six inches in thickness, cast and rolled armour were

essentially equal in ballistic performance in these vehicles.

Before and during World War II, moderately alloyed steels were employed for rolled armour. These steels contained up to 6%–8% total alloy content with chromium-molybdenum-vanadium, chromium-nickel, chromium-nickel-molybdenum and nickel-molybdenum-vanadium alloy steels predominating. These steels were hardened by being heated, air cooled or oil quenched, and then tempered to the desired hardness. The early tank armour steels often contained from 0.35% to 0.50% carbon and, because of both high carbon and alloy contents, were not considered weldable. Alloy shortages during World War II required all combatant nations to cut back on the alloy content of their armour steels, and the change-over to welded construction necessitated a reduction in carbon content to the range of 0.25%–0.30%.

With the reduction in heat-treatment response occasioned by lower carbon and alloy contents, the United States resorted to water-quenching practices to harden armour steels, and found that the over-all mechanical, metallurgical and ballistic qualities of the drastically quenched low-alloy armour steels were uniformly superior to those of the older highly alloyed steels. Small traces of boron and other needling compounds were added to rolled armour steels to increase their hardening ability and these additions permitted the scarcer alloys such as nickel, chromium and molybdenum to be either eliminated or drastically reduced. Manganese was also employed as an alloying element to conserve alloys in short supply, and manganese-molybdenum, manganese-molybdenum-boron and manganese-chromium-molybdenum steels containing often less than 2% alloy content were used from 1942 on.

The British generally retained the oil-quenching practice for hardening armour steels, and consequently required higher alloy contents than prevailed in U.S. practice. The Germans employed a variety of alloy compositions among which chromium-nickel and manganese-chromium-silicon steels were included. Severe alloy shortages during the latter years of World War II caused a drastic cutback in alloys available for armour manufacture, and by the end of the war the Germans often used as-rolled carbon steels for tank armour. The Soviets generally employed rather highly alloyed steel for armour, and a manganese-silicon-chromium-nickel steel was widely used, which was often heat-treated to considerably higher hardnesses than the same thicknesses of armour made by other nations.

During the years from 1916 to 1940, tank hulls and turrets were fabricated by riveting and bolting together rolled armour plates. Such structures performed adequately against the small-calibre armour-piercing projectiles which then prevailed. When struck by larger-calibre shot, however, the rivet heads were sheared off by the shock impact and could rebound within the crew compartment at high velocities and cause severe casualties. During 1941–42 a complete change-over was made to welded construction since, after an accelerated development effort, it was found possible to weld together both cast and rolled armour to produce joints having a high resistance to ballistic attack. Welding was initially performed with high-alloy steel electrodes containing up to 25% chromium and 20% nickel which produced extremely tough joints. Wartime shortages of alloys necessitated the development and use of low-alloy welding rods and several low-alloy steels were successfully employed for welding electrodes.

The principal factors governing the degree of protection afforded by armour are its thickness and its angle of slope with respect to the line of fire. The thickness of armour is critical in determining the weight of vehicles, and a constant struggle faces armoured-vehicle designers who must decide whether to reduce armour thickness to increase the mobility of vehicles or increase armour thickness to maximize the protection afforded by it. Steel armour one inch in thickness weighs 40.8 lb. per square foot. A light tank fitted with more than 500 sq.ft. of one-inch-thick armour would thus carry more than ten tons of armour. Highly sloped armour is effective in causing breakup and deflection of shot. It also lengthens the path through the armour taken by a penetrating projectile, thus absorbing more of the latter's energy. With a given weight of armour to shield a fixed volume of space behind it, considerably greater protection is afforded by using a longer, thinner plate sloped at an angle of 60° from the line of fire than by using a shorter, thicker plate positioned perpendicular to the line of fire. Advantageous use of highly sloped armour was made early in World War II. German tanks and highly sloped armour designs were quickly adopted by Soviet, British and U.S. tank designers. The frontal armour on hulls and turrets of tanks was sloped at angles in the range of 50°–60°, and the Soviets, by using compound slopes on the front of the JS–3 tank, achieved angles of 70° from the line of fire. Cast armour readily lent itself to highly sloped designs wherein full hulls and turrets could each be cast in one piece, and the thickness of the armour was adjusted to provide thicker sections in the less highly sloped areas and thinner sections in the more highly sloped areas. By the end of World War II, tank designs had evolved to the point where it was possible to design armoured vehicles to achieve equal levels of protection from selected calibres of projectiles striking any frontal area from any direction of fire.

The table presents a picture of the hull and turret armour dispositions on World War II tanks and is generally representative of vehicles made by all the major belligerents.

Type of tank	Tank weight (tons)	Frontal armour		Side armour thickness (in.)
		Thickness (in.)	Angle of slope	
Light	15–20	1.0–1.5	45°–60°	0.75–1.0
Medium	25–45	2.0–4.0	30°–60°	1.5 –2.0
Heavy	50–65	4.0–6.0	50°–70°	2.0 –3.0

Three developments in antitank weapons made during World War II rendered armour considerably more vulnerable to attack. The first was the improvement in antitank guns and propellants that enabled muzzle velocities to increase from approximately 2,000 ft. per second at the beginning of the war to 3,500 ft. per second by its end. Since the energy of projectiles increases with the square of the velocity, this produced a threefold increase in the penetration ability of projectiles. The superiority of the much vaunted German 88 was attributable to the fact that this gun, thoroughly tested in the Spanish civil war, had a muzzle velocity of approximately 3,400 ft. per second. The second development was the use, first by the Germans, of armour-piercing projectiles which had light outer cases and armour-piercing cores of tungsten carbide, an extremely hard substance almost twice as heavy as steel. Because the over-all weight of these projectiles was less than that of conventional solid steel shot, they could be fired at higher muzzle velocities and since only the relatively small core penetrated the target, a large amount of energy was applied to a small target area, resulting in very much greater penetration. The third and most potent development in armour-defeating ammunition was the shaped-charge or "bazooka" round first used by the U.S. army. This ammunition contains a charge of high explosive cast behind a conical metal liner. When the charge is detonated the liner is collapsed and projected forward as a narrow beam of extremely high-velocity incandescent particles which perforate armour much as a high-velocity water jet blows through an earth embankment. (*See* AMMUNITION, ARTILLERY.)

Defense against these improved armour-defeating rounds was often improvised during World War II by bolting additional thicknesses of armour around tank turrets and to hull fronts, by attaching sandbags around turrets, by spaced armour arrangements and by attaching spare sections of track to the glacis, or upper hull front plate. Later designs involved placing tool boxes and other battle-expendable gear on the outside of the tank so that projectiles might be deflected or caused to function prematurely before striking the main armour.

Tests have demonstrated that armour plating offers considerable advantages in nuclear warfare. By virtue of their necessarily rugged construction to withstand attack by armour-piercing and explosive ammunition, tanks, armoured cars and personnel carriers offer a high level of protection against the blast effects, shock waves and thermal radiation generated by the detonation of atomic weapons. The armour plating on even lightly armoured vehicles provides adequate protection against the alpha- and beta-particle

radiation from nuclear bursts, but steel armour on the heaviest tanks (six to eight inches thick) is not sufficient to shield crews from gamma and neutron radiation. It is possible, however, to provide a high degree of shielding capability to armoured vehicles by inserting within their armour envelopes additional materials capable of absorbing highly penetrative radiation. Lead and other materials of high atomic number provide good shielding from gamma radiation while paraffin and other hydrogenous materials are effective in decreasing neutron flux. Combinations of such materials, in conjunction with the basic steel armour, can be effective in providing immunity from the destructive effects of atomic explosions even at moderately short range.

Nuclear weapons may be used not only for their direct destructive capabilities but also to deny the enemy access to transportation routes and strategic areas by rendering these radioactive. It is very probable that specially modified armoured vehicles could be used extensively in atomic warfare to transport troops and equipment through radioactive areas.

Aircraft Armour.—Aircraft armour came into use in the years following World War I and was extensively used during World War II. Aircraft armour falls into two distinct categories: fixed armour attached permanently to the aircraft structure, and movable armour either worn by air crewmen or suspended around them as protective curtains. Aircraft armour must, of course, be of minimum weight since weight detracts so greatly from the speed, range and maneuverability of aircraft. Fixed armour is generally applied to fighter planes and low-flying aircraft used in support of ground troops, and is often formed into seats to protect the pilot from attack from the rear and from beneath. The engines and vulnerable areas of engines, controls and instruments are also protected by armour in some types of aircraft. Armour installations of these types are generally intended to provide protection from calibres .30 and .50 machine-gun fire from hostile aircraft and from machine-gun and rifle fire from the ground.

The materials most often employed for aircraft armour during and after World War II included hard homogeneous and face-hardened (either carburized or nitrided) steel, nonmagnetic alloy steel armour (sometimes used around magnetic and electrical equipment) and aluminum alloy armour. Steel aircraft armour is generally one-fourth to one-half inch thick (10–20 lb. per square foot) and is made of higher-alloy steels than corresponding thicknesses of tank armour since it was found that the higher-alloy steels could be heat-treated to possess better toughness at very high strength levels. Aluminum alloy armour was successfully employed to protect low-flying aircraft used by the United States navy in the Korean war. Plates attached to the entire undersurface of the aircraft offered considerable protection from small-arms fire.

Movable aircraft armour was most often used to protect bomber crews. Armoured jackets containing overlapping steel platelets very similar to medieval body armour were developed in 1943 to protect bomber crews of the U.S. 8th air force from the heavy flak encountered over Germany. These proved very effective and armour developments were extended to the point where complete armoured outfits including helmets, jackets, aprons and groin coverings were issued to bomber crews. The armoured clothing could be readily discarded by pulling a ripcord. Armoured flexible curtains were also used to protect defensive machine-gun emplacements on bombers. While the fixed armour installed in fighter and strafing aircraft was intended for protection from machine-gun and rifle bullets, the flexible armour used in bombers was designed to offer protection primarily against shell fragmentation from antiaircraft cannon. (A. Hu.)

ARMOURED CAR. The military armoured car is a wheeled motor vehicle with light protective armour, usually equipped with machine guns or a light artillery piece and a radio. It is used chiefly for reconnaissance or for pursuing a fleeing enemy. Civilian armoured cars are far less elaborate than their military counterparts, often being simply standard passenger cars equipped with bulletproof glass and with armour plate concealed in the upholstery to provide protection against small-arms fire. They are used in many countries for the protection of high government officials against assassins.

For the early history of armoured vehicles, *see* TANK: *Predecessors.* The use of armoured cars in modern times is said to have originated with European smugglers before World War I; some smugglers' cars were designed so they could be driven and steered from either end to facilitate escape when faced with road barricades erected by customs officials. During the first half of the 20th century many commercial firms used armoured trucks manned by armed guards to transport money or valuables.

The origin of military armoured cars in the United States may be traced to 1898 when Maj. R. P. Davidson of the Illinois national guard built at the Duryea corporation in Illinois a light car equipped with a small steel shield and a Colt machine gun. At the same time, F. R. Simms in England built a similar car. But in neither country were the military authorities favourably impressed. In the years that followed, inventors nevertheless continued to develop new and improved types, including some powered by steam. In 1903 Simms brought out a six-ton vehicle with two rotating turrets, and the following year the French firm Charron, Girardot et Voigt built a completely armoured and turreted car. With horse cavalry fast losing its importance in the face of barbed wire and new rapid-firing weapons, military men began to take an interest in the great variety of armoured vehicles offered by inventors. Italy is generally credited with giving armoured cars their baptism of fire in actual military operations against Tripoli and Cyrenaica in 1913. Meanwhile, Germany, Russia, France and other countries experimented with various types of military cars and used them in World War I, improvising tactics as they went along. The great difficulty with all such machines was that, because of their weight, they easily bogged down in mud or sand, in spite of having four or more driving wheels.

BY COURTESY OF DEPARTMENT OF DEFENSE; U.S. ARMY PHOTOGRAPH

M-75 ARMOURED TROOP CARRIER

Continued efforts went into development of improved armoured cars as "motorized cavalry" in the 1920s and 1930s. After the outbreak of World War II, British forces employed a half-dozen different types with good results. Germany used a light four-wheel car with a 20-mm. automatic gun, several types of eight-wheel cars (with power at all wheels), and a variety of half-tracked armoured personnel carriers. The standard light armoured car of the U.S. army in World War II was a six-wheeled vehicle with power at all wheels. It carried one 37-mm. gun and two machine guns, all mounted in a turret. Smaller four-wheel cars known as "scout cars" also saw service, as did a seven-ton armoured utility car that mounted one machine gun and carried six men. Larger armoured vehicles equipped with wheels in the front and tracks in the rear were known as "half tracks," and still larger armoured vehicles, as large as tanks, took the name of "gun motor carriages." After World War II the U.S. army retained its four-wheel scout cars but discarded its large armoured cars because they had insufficient cross-country mobility. The U.S. army gave increased attention

to armoured personnel carriers that rode on tracks rather than wheels.

In the 1950s the British army made use of two types of armoured cars known as the Saracen and the Saladin. The latter had six driving wheels, mounted a three-inch gun in a revolving turret and was employed for reconnaissance and pursuit. The Saracen, also a six-wheel-drive vehicle, was an armoured personnel carrier capable of accommodating 12 men, including driver and commander. Of the many Russian types the most widely used was the BA-64, a lightly armoured four-wheel car mounting one machine gun. The French army meanwhile adopted the EBR (Engin Blindé Reconnaissance) designed and manufactured by the Panhard firm. It mounted a 75-mm. gun and could travel forward or backward at high speed on good roads. A unique feature of the EBR was a double set of cleated metal wheels that could be lowered for added traction when needed for cross-country mobility.

See Charles R. Kutz, *War on Wheels* (1940); Robert J. Icks, *Tanks and Armoured Vehicles*, ed. by Phillip Andrews (1945). (H. C. T.)

ARMOURED FORCES are bodies of troops who move and, for the most part, fight in automotive vehicles. Their equipment includes tanks and other vehicles provided with varying amounts of protective armour. However, the term armoured forces, frequently abbreviated to armour, gives undue emphasis to the least important of the three characteristics—weapon power, mobility and protection—of such forces. It is less appropriate than the earlier and synonymous term mechanized forces.

World War I.—Tanks are the principal fighting vehicles of armoured, or mechanized, forces and in general the evolution of the latter followed the introduction of the former in 1916.

The first properly constituted armoured units were detachments of armoured cars attached to French cavalry corps from Sept. 1914 and the armoured car squadrons of the Royal Naval air service created between Sept. and Dec. 1914. The decision to form the first tank units was taken by the British army in Feb. 1916; in June the organization of what was called the heavy section, machine-gun corps, was fixed at six companies, each of 25 tanks. Three months later two companies were rushed into action to bolster a British offensive on the Somme and on Sept. 15, 1916, tanks were used in battle for the first time. They achieved little, but their moral effect was sufficient to induce an expansion of the British tank forces to nine battalions of 36 tanks each.

The formation of French tank units also began in 1916, but they did not go into action until April 16, 1917, when 128 tanks, organized into *groupes* of 16, were used in a manner consistent with their designation as *artillerie d'assaut*. They achieved little, mainly because of the limited trench-crossing ability of the vehicles. Similarly, further employment of British tanks, particularly at Passchendaele in July 1917, met with little success because of inept piecemeal use over unsuitable ground that had been turned into a morass of mud by prolonged shelling and rain.

It was on Nov. 20, 1917, at Cambrai that British tanks were first used effectively in a massed surprise assault over suitable ground. The whole of the newly formed tank corps was concentrated, nine battalions with a total of 476 tanks, and the result was a spectacular break through a triple line of trenches, but the success was not exploited.

At Amiens, in Aug. 1918, all the available tank corps units were again concentrated—11 battalions with 604 tanks—and the success of Cambrai was repeated. In July 1918 the French army also used tanks in mass at Soissons, where about 480 tanks were assembled. Numerous smaller actions followed and the number of Allied tank units grew. By Nov. 1918 the British army had 18 tank battalions in France and 8 in training. The French had 21 light tank battalions and smaller units of medium tanks. The U.S. army created a tank corps, in Jan. 1918, and planned to expand it to 15 brigades, each of 3 battalions; only 3 battalions were actually equipped—with British and French tanks. The German army lagged far behind in the employment of tanks. It formed its first detachment of 5 tanks in Jan. 1918, but up to the end of the war only 20 German tanks were completed against 2,636 British and 3,870 French.

In addition to numerical expansion, the Allies had also planned new tactics for 1919. Methods practised so far had consisted of frontal assaults executed by waves of tanks advancing behind an artillery barrage and followed closely by infantry, which mopped up and occupied entrenchments overrun by tanks. The principal task of the tanks was to destroy hostile machine guns, and they worked closely with the infantry distributed by companies or battalions between infantry brigades or divisions. But in 1918 the British tank corps planned an extension of the heavy tank and infantry frontal assaults by sending units of faster medium tanks through against headquarters and other objectives behind enemy lines. The French army elaborated the technique of the tank breakthrough by echeloning tanks in two waves, the leading wave consisting of very heavy tanks and the second of light tanks which brought on the infantry.

Post-World War I Developments.—All the plans were nullified by the Armistice of 1918. The development of tanks was halted and it was even argued that there was no future for them beyond the siegelike conditions of trench warfare. Tanks survived not because their wider potentialities were recognized but because they came to be regarded as a useful auxiliary to the infantry, and most tanks were retained in this role up to the outbreak of World War II. The French army had a large number of light tanks—3,737 in 1921—which were suitable for little apart from an infantry-accompanying role, and in 1920 it made tank regiments an integral part of its infantry. This example was followed by armies of other countries, including that of the United States. The accepted practice was to attach a tank battalion to an infantry division and to split it by companies among infantry battalions. The only more advanced method was the use of the more powerful tanks ahead of the light infantry-accompanying tanks along the main line of effort of the supported infantry division or corps. Tanks intended for this role were designated "leading tanks" by the U.S. army and *chars de manoeuvre d'ensemble* by the French.

A notable exception to the prevailing trend was the position of tank units in the British army. Although reduced to four battalions they were formed in 1923 into the royal tank corps and their relative independence, together with new, more mobile equipment in the shape of about 160 Vickers medium tanks, provided opportunities for the development of new operational methods. The first step was the formation, in May 1927, of an experimental mechanized force. This consisted of a battalion of medium tanks and other armoured and motorized infantry and artillery units and was the first self-contained force based on motor vehicles. In 1928 it was renamed the armoured force and then disbanded, but its trials set off a series of experiments toward a mobile employment of tanks, no longer tied to the slow pace of the infantry, and foreshadowed the armoured forces of the next decade.

In July 1928, as a direct result of the British experiments, an experimental mechanized force was assembled in the United States at Ft. Meade, Md. It was quickly disbanded, but the experiment was resumed in 1930 at Ft. Eustis, Va., and this led to the formation, between 1932 and 1938, at Ft. Knox, Ky., of the 7th cavalry brigade, mechanized. British trials also influenced the exercises held in France in 1932 and other contemporary mechanized experiments in the U.S.S.R. and Germany. In Britain itself experiments were resumed in 1931. and the establishment of 1st tank brigade of the royal tank corps in 1934 provided the first instance of as many as four tank battalions maneuvering together under one command; it pioneered the technique of operating large numbers of armoured vehicles and demonstrated a far more mobile and effective use of tanks.

Some of the inspiration for this originally came from the technologically more advanced field of naval warfare, but although the influence of analogies between tanks and warships helped to free the former from the confines of trench warfare, it also strengthened an unfortunate tendency to create mechanized "fleets" of tanks. More practical and lasting were comparisons with cavalry, whose roles were gradually assumed by mobile armoured forces. With the development of faster tanks, mechanized forces had acquired the ability to perform the functions of a mobile arm and filled the place left vacant by horse cavalry. Un-

fortunately, armoured forces were not regarded as the decisive mobile arm which cavalry once was, and which armoured forces proved to be during World War II. They were confined to the strategic reconnaissance and exploitation to which horse cavalry had been reduced toward the end of its existence.

This was illustrated in Britain by the mobile division of 1937–38, which combined the tank brigade with two mechanized cavalry brigades equipped with light tanks. In France formations with similar limited roles were evolved by a gradual mechanization of horse cavalry divisions; the first *division légère mécanique* was formed in 1934 and although its organization resembled that of the later armoured divisions it was still only intended for a limited cavalry role. The same applied to the 7th U.S. cavalry brigade and the contemporary Soviet mechanized brigades.

German Panzer Divisions.—The advance beyond the confines of the limited cavalry role and toward the fullest use of tanks was left to the *Panzer* divisions. Conceived as versatile fighting formations, they combined tanks with other arms into new-style divisions which had greater striking power and greater mobility than other contemporary formations; they were equally capable of obtaining a decision in battle and of mobile exploitation after it. The first three were created in Oct. 1935 and by the outbreak of World War II there were six. By then each consisted of a tank brigade with four battalions, a motorized infantry brigade with four rifle battalions, an artillery regiment, reconnaissance, antitank and engineer battalions and service units. They formed the decisive striking force of the German army in its campaigns against Poland in 1939 and against France in 1940. In the latter case there were ten divisions incorporating all the German tanks in the field—2,574 out of the 3,400 which Germany possessed. Nine out of the ten divisions, concentrated in four *Panzer* corps, broke through the French front and by a rapid drive to the channel coast virtually decided the campaign. The number of *Panzer* divisions was soon doubled and in 1941, 17 of them, grouped in 4 *Panzer* armies, spearheaded the German invasion of the U.S.S.R. by a series of deep thrusts.

In 1939 other armies still divided their armoured forces into tank units for infantry support and mechanized formations for limited mobile roles. The former predominated, organized into battalions or, in the British and Soviet armies, into brigades, but the latter only for administrative purposes. The French army formed its more powerful infantry tanks into divisions intended to break through enemy lines. They were all used piecemeal, in their limited roles, and were routed accordingly. In France, in 1940, the Germans defeated, one by one, four infantry *divisions cuirassées* and three cavalry *divisions légères mécaniques*, as well as one British armoured division and smaller tank units (the French army alone possessed 3,800 modern tanks). In 1941 the Germans defeated Soviet armoured forces whose stock of tanks amounted to more than 20,000 against Germany's 5,264, out of which only 3,350 were actually deployed against the U.S.S.R.

Armoured Divisions.—The successes of the German *Panzer* divisions during 1939–41 provided an example to other armies, which made haste to create a maximum number of armoured divisions on the German pattern. Thus, in July 1940 the U.S. army abandoned the separation of tanks between the infantry and cavalry and created an armoured force with 2 armoured divisions, subsequently expanded to 16. The British army started the war with only 2 incomplete armoured divisions but after 1940 raised the total to 11, although it also retained a large number of tank units for infantry support and, unlike all others, continued to dissipate its efforts between the narrowly specialized categories of cruiser and infantry tanks. Italy completed the formation of three armoured divisions created in 1939, and Japan formed its first two in 1940, followed by a third later. Even Australia, with all its logistical problems, created three armoured divisions in 1942. The Soviet army employed a total of 65 tank divisions during the 1941 campaign and although they were lost through inept piecemeal employment it managed to rebuild its armoured forces, creating 258 tank brigades. The German army itself raised its total to 25 armoured divisions in 1942, subsequently joined by 8 *Waffen-SS. Panzer* divisions. The production of armoured vehicles greatly increased after 1940; German tank production rose from 1,460 in 1940 to a peak of 9,161 in 1944; British production rose much more rapidly from 1,399 in 1940 to its peak of 8,611 in 1942, and the U.S. even more so, from a mere 331 in 1940 to 29,497 in 1943.

Campaigns of World War II.—In the meantime, major campaigns continued to be decided by armoured formations. One British armoured division played a decisive part in the defeat of the Italian forces in Cyrenaica in 1940–41, and the subsequent counterstrokes of the Germans owed their success to the concentrated employment of two *Panzer* divisions. It was not until three British armoured divisions and 1,441 tanks, backed by a reserve of 1,230, were concentrated at El Alamein in 1942 that the German force with its 219 tanks was crushed. In Russia the major effort of the 1942 campaign was made by two *Panzer* armies which had nine *Panzer* divisions and 1,900 tanks, and the decisive Soviet encirclement at Stalingrad was led by tank and mechanized corps. For its last major offensive in Russia, against the Kursk salient in July 1943, the German army again concentrated 17 *Panzer* divisions; it never had the resources for another large-scale offensive, but *Panzer* divisions continued to play an important role in local counteroffensives and as the mainstay of the German defense against the Soviet advance which, in turn, was spearheaded by six tank armies.

In the west, in 1943, as operations shifted from Africa to less favourable conditions in Europe, emphasis was again placed on small tank units for close infantry support and the once discredited doctrine that armoured formations could only be used for exploitation reappeared. The British army retained only five armoured divisions. By the end of the war the U.S. army had no less than 60 independent tank battalions, intended chiefly for infantry support, which contained more tanks than its armoured divisions. Nevertheless, three British armoured divisions played an important role in the 1944 Normandy campaign, where they tied down the bulk of the opposing *Panzer* forces and thus helped the breakout of the bridgehead elsewhere; U.S. armoured divisions played a major part in the drive across France and the fighting on the German border. When fighting stopped in 1945 western Allied armies contained 28 armoured divisions—16 U.S., 5 British, 3 French, 2 Canadian, 1 South African and 1 Polish. However, they never used their armour in the concentrated and decisive manner which had marked German operations, but relied on an over-all numerical superiority and masses of tanks spread over a wide front in different type units.

The 1944 Normandy campaign was noteworthy for the large-scale use of tanks in an amphibious assault landing. Ten British and United States amphibious tank battalions were prepared for it and, altogether, amphibious and other tanks landed in the British-Canadian sectors amounted to three brigades, which accounted for much of the success of the assault. D-day in Normandy was also notable for the first use of air-borne tanks, seven British Tetrarchs being landed by glider. Even greater was the use of amphibious armoured vehicles by U.S. forces in the Pacific. Called "landing vehicles tracked," or LVT's, they were originally adopted in 1940 by the U.S. marine corps as unarmoured supply carriers, but on Tarawa in Nov. 1943 they were employed as armoured assault carriers and were then joined by turreted gun versions. Eight marine and army LVT battalions led the amphibious assault on Saipan in June 1944, and by the end of World War II the marine corps alone had 12 LVT battalions in the Pacific.

Post-World War II.—After World War II doubts arose once more about the future of armoured formations. Their full effectiveness was not recognized, nor was the advantage of concentrating tanks in fully mechanized forces instead of dispersing them among the less mobile infantry formations. The effect of armour-piercing weapons was exaggerated and there were doubts about tanks because their value was still wrongly supposed to be in their armour protection. In consequence, British and U.S. armoured forces were cut down to one division each. Only the Soviet army maintained large armoured forces, reorganized into tank and mechanized divisions, in place of the earlier tank and mechanized corps. The mechanized corps corresponded to the German *Panzer*

grenadier divisions and were, in essence, motorized infantry formations with some tanks; the tank corps, and the later tank divisions, corresponded to the NATO armoured divisions mentioned below. According to NATO estimates, in 1953 the Soviet army had 63 tank and 36 mechanized divisions and, in striking contrast to the NATO armies, the ratio of Soviet armoured to infantry formations had increased to one to two.

The growth of the Soviet armoured forces and the havoc wrought in Korea in 1950 by Soviet-built tanks helped to revive NATO armoured forces; the number of armoured divisions in western Europe increased to 11—3 British, 3 French, 3 Italian, 1 U.S. and 1 Belgian. The position of the armoured forces was later strengthened by the premium placed on mobility and dispersion by tactical nuclear weapons. Their vehicles, with all their armament and communications equipment, provided the necessary basis for mobile ground tactics and effective dispersion. The same vehicles also offered the possibility of effective operation in relative proximity to nuclear explosions by virtue of their inherent protection against blast and radioactivity, first demonstrated in May 1955 by the participation of an armoured task force in U.S. nuclear tests in the Nevada desert.

Organizational Developments.—To fulfill their potentialities, armoured forces had to undergo several changes in organization and tactics. The first advance beyond the primitive basis of battalions of 30 to 60 tanks was the formation of tank brigades. These, typified by the British tank brigade of 1934, combined up to four tank battalions under a single command and marked the first attempt at more mobile and effective employment. However, the capabilities of such all-tank formations were sufficient for a limited "cavalry role" but not for more effective and versatile employment. They were displaced by armoured divisions which combined a tank brigade with a complementary brigade of motorized infantry, a regiment of artillery and an engineer battalion. Such, in essence, were the *Panzer* divisions and most other armoured formations at the beginning of World War II, and the relative lead of the former in the effective combination of different arms accounted for much of their initial tactical success.

Once the interdependence of tanks and other arms was recognized, their combination spread down to subdivisional battle groups, such as the German *Kampfgruppen*. This was followed by the reorganization of armoured formations into self-contained battalions of different arms which could be combined into combat commands or other mixed brigade-size tactical groupings. This type of organization was introduced by U.S. armoured divisions in 1942–43, but toward the end of World War II the combination of different arms spread down even lower and after the war led to still smaller mixed units, such as the tank regiments of the Soviet divisions and the French *régiments inter-armes*, which combined riflemen with tanks and other heavy equipment into battalion-size mechanized units.

The formation of mixed armoured battle groups was greatly helped by the provision of self-propelled gun carriages and armoured personnel carriers. The former came into widespread use in 1942, although up to 1945 only the artillery of the U.S. armoured divisions was fully equipped with them. Armoured carriers, of the half-track type, were used by the *Panzer* divisions in 1940, but up to the end of World War II only one out of the four rifle battalions in each division was fully equipped with them. The same applied to the contemporary British divisions, but the three armoured infantry battalions of each U.S. armoured division were fully equipped with half-track armoured carriers, and after World War II the U.S. army led in the development of fully tracked carriers. The lack of armoured personnel carriers had been responsible for much of the opposition to including infantry in armoured formations by those who wished to exploit the mobility of tanks to the utmost, and who regarded the unarmoured wheeled vehicles of the motorized infantry as an unwarranted drag. In practice the combination proved essential, but the problem of large numbers of unarmoured vehicles remained. The *Panzer* division of 1939, with 328 tanks, had 2,095 other vehicles and 1,294 motorcycles. This led to the problem of fuel supply, which has risen steadily and which is the Achilles' heel of armoured formations. The *division légère mécanique* of 1938, with 220 tanks, 1,780 wheeled vehicles and 1,500 motorcycles, required 38,400 U.S. gallons (32,000 imperial gallons) to move 100 mi., while the 1950 U.S. armoured division, with its 373 tanks, 636 other armoured vehicles and 2,094 trucks, required 228,000 U.S. gallons (190,000 imperial gallons) to move the same distance.

Tactics also changed. The initial successes of the *Panzer* divisions were based on the firepower of their tank brigades used in mass, and the speed with which they attacked. The rapid tempo of the attack gave a minimum of time to opposing defenses and the concentration of the tank brigade on a narrow front ensured saturation at the decisive point. After the latter part of World War II these methods were superseded by the employment of progressively smaller subdivisional teams of all arms, ensuring closer co-operation between complementary elements under conditions of mobile warfare over wide fronts. Each mixed armoured battle group forms a mechanized multiple-weapon system well fitted to uphold the importance of armoured forces under conditions of dispersed mobile operations. *See* TANK; ARMOURED CAR.

(RD. M. O.)

ARMSTRONG, ARCHIBALD (d. 1672), court jester, called "Archy," was a native of Scotland or of Cumberland, and according to tradition first distinguished himself as a sheep stealer; afterward he entered the service of James VI, with whom he became a favourite. When the king succeeded to the English throne, Archy was appointed court jester. He became presumptuous, insolent and mischievous, excited foolish jealousies between the king and Henry, prince of Wales, and was much disliked by the members of the court. In 1623 he accompanied Prince Charles and the duke of Buckingham in their adventure into Spain, where he was much caressed and favoured by the Spanish court and, according to his own account, was granted a pension. His conduct there became more intolerable than ever. He rallied the infanta on the defeat of the armada and censured the conduct of the expedition to Buckingham's face. Buckingham declared he would have him hanged, to which the jester replied that "dukes had often been hanged for insolence but never fools for talking." He retained his post on the accession of Charles I and accumulated a considerable fortune, including the grant by the king of 1,000 ac. in Ireland. After the death of Buckingham in 1628, whom he declared "the greatest enemy of three kings," the principal object of his dislike and rude jests was Archbishop Laud, whom he openly vilified and ridiculed. He died at Arthuret, Cumberland, in 1672, and was buried on All Fools' day. *A Banquet of Jests: a Change of Cheare*, published about 1630, a collection chiefly of dull, stale jokes, is attributed to him and with still less reason probably *A Choice Banquet of Witty Jests . . . Being an Addition to Archee's Jests, Taken Out of His Closet But Never Published in His Lifetime* (1660).

ARMSTRONG, HENRY EDWARD (1848–1937), one of the most outstanding personalities in British chemistry who did much to improve the teaching of science and reveled in controversy. Born on May 6, 1848, at Lewisham, Kent, he studied chemistry from 1865 to 1867 under Edward Frankland (*q.v.*) at the Royal College of Chemistry (afterward united with the Royal School of Mines), London, and went to Germany to study under Hermann Kolbe (*q.v.*) at Leipzig in 1867, returning in 1870. In 1871 he became professor of chemistry at the London institution, Finsbury circus (later Finsbury Technical college), and in 1879 was appointed with W. E. Ayrton to organize the teaching of chemistry and physics at the City and Guilds of London institute. In 1884 he became professor of chemistry in the new Central institution, South Kensington (which became the Central Technical college in 1893), retiring in 1911 when the college became part of the Imperial College of Science and Technology. He was elected a fellow of the

Royal society in 1876. He was secretary of the Chemical society from 1875 to 1893 and president from 1893 to 1895.

Armstrong's first original work (with Edward Frankland) led to a method for the determination of organic impurities (sewage) in drinking waters that resulted in typhoid fever becoming a preventable disease. His more classic researches in chemistry dealt with substitution in the hydrocarbon naphthalene, a problem on which he published some 60 memoirs, which, with the work of his collaborators, securely established the chemistry of a substance and its derivatives that were of the greatest technical importance in the dyestuffs industry.

Armstrong devised, independently of Adolf von Baeyer, a centric formula for benzene; he was a pioneer in crystallographic measurements of organic substances; he propounded the quinone theory of colour in organic compounds; he contributed much to the understanding of the chemical constitution of camphor and the related terpenes; and he opposed, often in picturesque terms, the ionic hypothesis of dissociation, preferring to explain chemical reaction as a kind of reversed electrolysis.

He died at Lewisham, by then part of Greater London, on July 13, 1937. (D. McK.)

ARMSTRONG, JOHN (1758–1843), U.S. soldier, diplomat and political leader, was born at Carlisle, Pa., on Nov. 25, 1758. He was a student at the College of New Jersey (now Princeton university) when the American Revolution broke out. He left his studies and became an officer in the continental army in 1775, eventually attaining the rank of major. At the close of the war, when distrust of the congress under the Articles of Confederation was rampant among officers of the army, it was apparently Armstrong who was the author of the "Newburgh Addresses" attacking the congress. The sentiment of these addresses had support among the officers until General Washington intervened. After the war, Armstrong married a sister of Chancellor Robert R. Livingston (*q.v.*) of New York, took up residence in that state and entered upon a political career.

He was for two brief periods a member of the United States senate, and, from 1804 to 1810, United States minister to France. With the outbreak of the second war with England in 1812 he served as a brigadier general, and later as secretary of war in the cabinet of President Madison. Although sharply critical of Armstrong, Henry Adams wrote (in his *History of the United States, 1801–1817*) that Armstrong as secretary of war "introduced into the army an energy wholly new," the results of which were apparent "for half a century." Armstrong died at Red Hook, N.Y., April 1, 1843. (E. E. R.)

ARMSTRONG, SAMUEL CHAPMAN (1839–1893), U.S. soldier and educator, was born on Maui, one of the Hawaiian Islands, on Jan. 30, 1839, the son of American missionaries. He graduated from Williams college, Williamstown, Mass., in 1862 and then entered the Union army, receiving the brevet rank of brigadier general at the end of the Civil War. His command of Negro troops led to his interest, after the war, in the care and education of Negroes. From 1866 to 1872 he served in the educational department of the Freedmen's Bureau (*q.v.*). Meanwhile, his interest led him in 1868 to found an industrial school for Negroes at Hampton, Va., and he served as its head until his death on May 11, 1893. After 1878 Indians were also enrolled in the Hampton institute, and Armstrong gave much of his time to the Indian question."

See *Samuel Chapman Armstrong, a Biographical Study* (1904) by his daughter, Edith Armstrong Talbot. (E. E. R.)

ARMSTRONG, WILLIAM GEORGE ARMSTRONG, BARON (1810–1900), English engineer who revolutionized the manufacture of large guns and invented high-pressure hydraulic machinery, was born in Newcastle Upon Tyne, Nov. 26, 1810. He studied law but also made scientific experiments and invented a hydroelectric machine, which generated electricity by steam escaping from an insulated boiler through nozzles. Abandoning law in 1847, he founded the engineering works at Elswick-on-Tyne to build hydraulic cranes. In 1850 he invented a hydraulic accumulator comprising a vertical cylinder into which water was steadily pumped under a sliding ram loaded with weights; by thus raising the pressure in the supply pipes to 600 lb. per square inch, hoists, capstans, turntables, dock gates, etc., could be worked anywhere.

Armstrong next concentrated on improving ordnance for the British army in the Crimea. The bursting pressure of cast-iron and bronze guns was low and he therefore shrunk metal rings onto an inner steel barrel, later coiling a strip of wrought iron into a long helix and welding it into a solid tube. He presented this invention to the nation in 1859, for which he was knighted and appointed director of rifled ordnance, Woolwich. He resigned in 1863 and returned to the Elswick works, where the sizes of ordnance were continuously increased until, by 1878, guns with a 17¾-in. bore, weighing 100 tons, were being manufactured. Armstrong designed powerful hydraulic machinery for controlling them, introduced both screw and wedge methods of closing the breech and, to increase accuracy of shooting, applied "rifling" by cutting spiral grooves in the bore to impart rotary motion to the shell. He was elected fellow of the Royal society in 1843 and, later, president of the British association. Created baron in 1887, he died at Cragside, Northumberland, on Dec. 27, 1900. (AR. S.)

ARMY is a term with a dual meaning: a sizable body of men armed and organized for the primary purpose of warfare on land; or the entire trained manpower serving a king or a state for the same purpose. The latter use includes the full-time professionals and the part-time reserves, but differentiates armed forces for land warfare from naval and air forces. For the history and modern condition of the principal armies of the world, *see* also under the country heading.

Throughout history, the character and organization of armies have changed. Social and political aspects of nations at different periods resulted in revision in the make-up of armies. New weapons influenced the nature of warfare and the organization of armies. At various times armies have been built around infantry soldiers, or mounted warriors, or men in machines. They have been made up of professionals or amateurs; of mercenaries fighting for pay or for plunder or of patriots fighting for a cause. Consideration of the development of armies must be made in the light of the times in which the particular army was forged and the campaigns it fought.

This article traces the development of armies to the mid-20th century and is divided into the following sections:

The many facets of the history, organization and structure of armies can be found in such articles as ARTILLERY; CAVALRY; ENGINEERS, MILITARY; OFFICERS, MILITARY; STAFF, MILITARY; etc. For a more complete listing *see* MILITARY AFFAIRS (ARTICLES ON).

I. ANCIENT ARMIES

The origin of armies cannot be dated. Nonetheless it may be assumed that the appearance of the city-states in Mesopotamia and Egypt, their continuous struggle for arable land and water rights, the creation of fortifications and the expansion of the city-states into kingdoms and empires must have been paralleled in those focal areas of the ancient world by the appearance and growth of army organization. Four types of armed forces may be discerned in the early history of the Fertile Crescent and the Nile valley. Paramount was a warrior caste which formed the ruler's bodyguard and "ate before the king." Much scholarly debate revolves around the origins, in the various states of antiquity, of this caste system. In some cases, the warrior caste simply represented the retention of arms in the hands of a conquering people who had disarmed and reduced to serfdom an earlier group of inhabitants. In other cases, the warrior caste appears to have been simply the product of birth or race. Next in importance to the guard attached

to the person of the monarch were the provincial troops who served in districts outside the capital under a royal governor or great prince. A third class of soldiery common in antiquity were the mercenaries, sometimes slaves as were the Nubians who served the first Pharaohs, or freebooters such as the Philistines, who were found in armies the length and breadth of the ancient near east. Finally, there seems to have existed from the earliest times, and in all societies, the institution of the *corvée* or forced levy of troops from the ordinary population. This levy was often associated with public works, but in wartime could augment the regular forces with lightly armed auxiliaries and road builders. They could also reinforce the mass of service troops by bearing burdens, building earthworks during siege warfare and burying the dead. As a rule, command in battle was personally exercised by the king, just as he performed the functions of chief priest and supreme judicial authority. Armies were regarded not as a drain on national revenues, but rather as an economic instrument for building the wealth of the ruler through the acquisition of slaves, booty and tribute.

Sumeria.—The Sumerians provide the first historical evidence of an army organization, this in the 4th millennium B.C. The so-called "standard," discovered in one of the royal graves of Ur, depicts infantry in formal ranks, armed with short spears, wearing conical copper helmets and given body protection by thick cloaks. In this period, war chariots already were employed, but they must have been unwieldy and slow since they had four wheels of solid wood and were drawn by asses. Later the Sumerian army standardized on a 6-man-deep phalanx; the first rank went into combat carrying large rectangular shields and the troops bore heavy pikes and battle axes. There is some indication that Sargon I of Akkad broke the power of the kings of Lagash by using a more open formation against the unwieldy phalanx. Apparently, also, the armies of Akkad relied to a great extent on missile fire with the bow and the javelin.

Babylonia.—The code of Hammurabi provides a fairly detailed description of army recruitment and duties in Babylonia at the beginning of the 2nd millennium B.C. The regular army was recruited from a soldier class granted hereditary land rights by the king. While on foreign service the soldier had to pay one-third of the land's produce to his wife or son, but in this and other matters he was protected by special laws while on campaign. The regular soldier, as a member of the first social class, must have been rigidly disciplined because the penalties assessed for crimes of violence were more severe for this first class than for the lower social orders. The middle class, second in the social hierarchy, were subject to the military levy—possibly in return for the royal right to trade or fish—but their place in the army was that of light-armed archers or service troops. Ultimately they were allowed to purchase exemption from army duty.

About the 18th century B.C. a great barbarian irruption struck the Fertile Crescent from the northeast. These invaders brought horses and light, two-wheeled war chariots. Within two centuries this new arm had become fairly common, but the invaders, such as the Hittites and Mitanni, who had introduced the swift horse-drawn chariots, for a time held the palm. Despite recent archaeological finds, little is known of the army organization in the new states established by the invaders. The strength of their armies lay in the aristocracy of chariot warriors who held grazing lands as fiefs from the king. It is known that the Hittites had a state-controlled arms industry which, at the battle of Kadesh on the Orontes, permitted a Hittite king to put in the field 3,500 chariots and 17,000 foot soldiers. A Hittite code of laws shows that the army was assembled annually at a place designated by the king; it also fixed the terms under which the nonwarrior class had to care for the soldier's land while he was in service. Theoretically, the Hittite armies took the field only during the yearly campaigning season, but in fact one Hittite ruler kept an army in Syria for 20 yr.

Egypt.—In Egypt the armies of the old kingdom seldom fought foreign wars but were usually employed for plundering expeditions and slave raids. The soldiers depicted in hieroglyphs are Nubians, who were apparently used by the despotic Pharaohs in a combination military-labour *corvée* to build the great monuments. During the middle kingdom period the great princes raised armies on a fief system from free landowners; however, the art of war saw little development until the invasion of the Hyksos. Amasis I expelled the Hyksos by adopting their military techniques. He created a standing army of two divisions recruited from the free middle class and called "citizens of the army." His troops fought with copper battle axes and bows, using the quiver—brought from Asia—to give volley fire. Wings and centre, flanking movements, recruit training and cadence step were introduced at that time. Under Rameses II (reigned 1292–1225 B.C.) the Egyptian army reached its ultimate stage of organization. The professional standing army was augmented in time of war by compulsory service from a warrior caste. Body armour, consisting of laminated linen cloth and leather caps became uniform. The army tactical formations were standardized on a square 100 men deep; ration lists, organized wagon trains and a state armament industry are all found in the records. Nonetheless the armies of the empire which annually invaded Syria remained small, probably less than 20,000 men. Ultimately the Pharaohs lost their power to the priests and princes, and military service became a legal fiction. Herodotus says there were more than 400,000 military fiefs held by Nubian, Libyan and Greek mercenaries who had settled in Egypt.

Assyria.—The creation of the Assyrian empire by Assur-nasir-pal II in the 9th century B.C. introduced an army organized as a state; all political, cultural and economic life was subordinated to the support and perfection of the army. Wars were fed by wars. If a city fell to the sword, those of its defenders not massacred were enrolled in the Assyrian forces. If a kingdom bought its life and bowed as a vassal, the price included chariots, siege engines and soldiers. Nineveh was more than the capital city, it was a general headquarters handling thousands of military reports.

The royal army had as its shock troops, the king's bodyguard, but was permanently enlarged by conscription from fief holders throughout the empire. In large operations, each village and each vassal kingdom furnished a contingent of troops. The size of the Assyrian armies cannot be reckoned accurately but on the eve of the empire age, Shalmaneser II (d. 824 B.C.) could boast of his ability to raise a levy of 120,000 men. The main strength of the Assyrian army lay in its archers, and mounted lancers who fought from horseback without saddles. To increase mobility, many of the infantry were mounted but actually fought on foot. A two-man team was developed to protect the archers, one man wielding the composite bow and the other carrying a man-size wicker shield. The regular soldiers wore cone-shaped helmets and breastplates with metal pieces sewed on leather or linen. A well-organized engineer corps conducted siege warfare and built roads or cleared obstacles. Siege engines, some of iron, became highly effective in the hands of the Assyrians—although it is not clear from the inscriptions what all of these machines were. Perhaps the greatest weapon of the Assyrian armies was the terror they inspired wherever they marched. The rapid collapse of the Assyrian empire at the close of the 7th century B.C. remains a historical enigma but may be ascribed in part to the depopulation by constant war of the original Assyrian provinces that furnished the backbone of the armies.

Persia.—The Persian empire, heir to the Assyrian, produced no new army organization or tactical concepts. At the centre of the Persian army system, stood the hereditary Persian warrior caste, bound by ties of blood to the ruler and known as his "companions." Like those of Assyria the armies of the Persian kings relied on chariots, cavalry and archers. Unlike the Assyrians, the Persians lacked a well-disciplined, heavily armed infantry. Ultimately the Persians turned to the mercenaries of Greece in an attempt to give tactical stability to the lightly armed levies that composed the bulk of their great armies. However, the Persian army destroyed by Alexander the Great was essentially the same as that which conquered Nineveh.

Greece.—In Greek history, warfare was a normal state and seasonal occupation. With the disappearance of the Homeric age marked toward its close by the Trojan War, the individual hero and bands of companions, whose feats in combat had ruled the battlefield, slowly were replaced by organized armies drawn in

time of need from the free citizens of the city-state. Each able-bodied male citizen as a youth received physical training adapted to military skills. Between the ages of 18 and 20 he did garrison duty on the border; thereafter he was liable to be called up with his age group for training or war. In Sparta, where the youth began continuous military training at the age of seven, the obligation to bear arms continued until the age of 60; but at the battle of Leuctra, as an example, only the classes 20 to 35 years old were in the ranks.

Originally a Greek citizen could personally equip himself for war and thus, since wealth was based on real property, the soldier-citizen was a landowner. The rich furnished the cavalry; the middle class provided the heavy infantry, or hoplites; and the poorer citizens served as lightly armed infantry or oarsmen in the navy. Ultimately, in some of the Greek cities, a class of landless citizens appeared who received pay for service in the fleet and, as in Athens, the navy became the "popular" service. Extraordinary military expenses for fortifications and ships normally were provided by free gifts from the wealthy or by profit from state enterprises in which all citizens shared; thus Themistocles took the proceeds from the Laurium (Laurion) silver mines to build the Athenian fleet and Pericles amassed a war chest from state profits and tribute. The Spartan system retained the citizen in garrison until the age of 30, and provided subsistence to all citizens on the basis of military rations from the state. According to tradition, from the time of the battle of Plataea onward, the Athenian soldier on long-term service received payment in coin. In the period of expansion after the Persian Wars, Greek economy became so solidly based on slavery that the only careers left to citizens were war or politics.

The tactical formation developed by the ancient Greeks and maintained throughout their history was the phalanx, an unbroken linear array of heavily armed infantry standing shoulder to shoulder in files that were normally 8 men deep but sometimes deeper. Apparently the use of the phalanx spread throughout Hellas during the 7th century B.C. The Greek hoplite who manned the phalanx was equipped for a standing fight in a warm climate with a round shield, a heavy corslet of leather and metal, greaves (armour for shins), an 8-ft. pike for thrusting and a 2-ft. double-edged sword. Since the phalanx held in solid ranks and was divided only into the centre and wings, there generally was little need for an officer corps; the whole line advanced in step to the sound of the flute. The Spartans, however, did train officers to maneuver the phalanx and appointed permanent generals who also held political office as kings. In Athens one of the archons (chief magistrates) elected for the year served as the field general.

The Greek cities calculated the strength of their armies in terms of the number of hoplites only. In Sparta, however, four or five lightly armed soldiers or slaves accompanied each hoplite, while in Athens and Thebes at least one light infantryman took the field with each member of the phalanx. Since there was little grazing land and because horseshoes, necessary for the stony ground of Greece, were unknown, the city-states paid scant attention to the cavalry arm. Neither Athens nor Sparta seems to have been able to put more than 10,000 citizen hoplites in the phalanx, but during the Peloponnesian Wars both doubled or trebled this number by the addition of allies and noncitizen residents.

Throughout the Hellenic age there was no major change in the organization of the Greek armies. The Greek city-states produced no innovations in tactics or weapons save the oblique phalanx, heavily weighted on the assaulting flank, which was developed by Epaminondas (*q.v.*) and which catapulted Thebes briefly to power. The long period of the Peloponnesian Wars bled white and impoverished the social classes which had formed the city-state phalanx and thus cleared the way for Macedonian hegemony (*see* PELOPONNESIAN WAR). But perhaps, as suggested by Arnold Toynbee, the toils of great traditions and universal contempt for all that was non-Hellenic in origin, made it impossible for the Greeks to discard the city-state, the phalanx and hoplite as these became obsolescent, thus hastening the imposition of rule by others who possessed new, vigorous political and military organizations.

Alexander.—Alexander's army was built around the phalanx, composed of his best Greek and Macedonian hoplites. Alexander's basic unit in the phalanx was the syntagma, normally 16 men deep, and each soldier armed with a spear (*sarissa*) said to be 21 ft. long. In battle, the first five ranks held their spears horizontally in front of the advancing phalanx, the files being practically on the heels of the men in front when in battle formation. The remaining 11 ranks presumably held their spears vertically or rested them on the shoulders of those in front.

This 256-man syntagma was unwieldy, particularly if its tight formation was broken by rugged ground. It had the advantage on level ground of being able to form a wedge, or a "V"; it could march to the flank, wheel and countermarch. Four of these bodies formed a chiliarchia, and four chiliarchiae, or 4,000 men, composed a grand phalanx. An army was composed of a grand phalanx supplemented by lightly armed soldiers (psiloi), cavalry and irregular troops.

In front of the core of the army, the hoplites of the phalanx, were slingers and archers while cavalry armed with swords and lances protected the flanks. When the lightly armed skirmishers were driven back in battle, they withdrew around the flanks to join the auxiliaries in the rear of the phalanx.

In Alexander's army were forerunners of modern artillery, the catapult and ballista, some siege equipment and even the first medical service. Hippocrates had left his imprint upon the Greeks to the extent that Alexander carried a personal physician while a man named Onasilos attended the warriors.

Alexander's army numbered between 30,000 and 40,000 in his campaigns in Asia Minor and India. Issus and Gaugamela were two of his greatest battles. Tactical skill in the use of cavalry on the flanks, while utilizing the phalanx as a solid centre line, brought Alexander overwhelming victories against massive Persian forces. Of great assistance was the prevailing breakup of an army when its leader had been killed or had fled. For at Gaugamela, Darius' hasty flight resulted in the complete undermining of the Persian will to fight. (*See* ALEXANDER III.)

Civil wars, the decline of the phalanx as a fixed fighting force and the breakup of his empire followed Alexander's death. The place of Greece and Persia in the history of warfare was taken by Carthage and the Roman republic in the Punic Wars of the 3rd century B.C.

Carthage.—The short-lived, mothlike history of Carthage's battle for supremacy in the western Mediterranean is one of brilliant generalship, supported reluctantly at home by the merchants. After the loss of Sicily, Sardinia and Corsica in the First Punic War, Carthage turned to Spain as a source of wealth and as a military base for operations against Rome.

Hannibal (*q.v.*) was the model of Carthaginian military greatness. In the service of a nation which little appreciated his gifted leadership, he welded together a fighting force of nonnationals—Numidians, Gauls, Africans, Spaniards and soldiers of fortune from the Mediterranean area. His leadership carried these diverse nationalities to victory after victory, much as did Albrecht W. E. von Wallenstein centuries later. These mercenaries, called into service only when needed and discharged when no campaigns impended, often rebelled or deserted since they had no patriotic motive for fighting. The military situation was consistent with the desires of the commercial men who dominated Carthage. They put their interest in a large navy, had no standing army and hired one only when the situation warranted.

Discipline was rarely good. It was not a national army supported by the people. The generals were chosen by the people, and control of operations was exerted by the senate who sent a deputy commander as its representative to make certain that the plans were carried out. Victory was achieved despite the system.

The model for the Carthaginian army was the Greek. Shock tactics by the centre, composed of Gauls, Spaniards and Libya-Phoenicians, were supported by heavy cavalry on the flanks and by numerous light Numidian cavalry. The skirmish line in front was composed of slingers and other light troops, and later a line of elephants. As the wars progressed, the phalanx took on the nature of the Roman legion while the Romans, in turn, copied the Carthaginian cavalry.

Hannibal was a master strategist in selecting the ground for battle so as to favour his troops. Furthermore, he employed ruse and stratagem to surprise the Romans. Much of his success was the result of an elaborate system of spies. He paid great attention to supply lines since his base in Spain was far from his operations in Italy. Also, the provision of weapons for his troops was a constant problem because of the nature of his mercenaries. For example, the Spaniards wanted swords for cutting and thrusting; the Gauls for cutting only. The African infantrymen preferred long lances and bows and arrows. The Numidian cavalry, armed with lances, darts and swords, used leopard skins as shields.

Hannibal employed his cavalry for shock action against the Romans at Cannae, following up after the successful onslaught by pursuit with the Numidian cavalry. As the wars wore on, it became obvious that Hannibal could never hope to defeat the Romans completely, he lacked naval support against a strong Roman navy, his supply lines were long and his recruitment of mercenary replacements depended on the whim of the Carthaginian senate and the availability of such soldiers of fortune. His polyglot army could not withstand the patriotic, consistent endeavours of the Roman citizen-soldiers.

Rome.—The history of Rome is the history of its armies. The strategic policy of Rome, if it can be so called, was to avoid the necessity of having a navy; save for the shipbuilding race with Carthage, the expansion of the Roman world was conducted by marching soldiers. The history of the Roman armies, in turn, is that of the legion (*q.v.*), which term in its origin may have meant those who were "chosen" for military service during the annual assembly of citizens. The legion cannot be considered a static organization because of its tactical form; its equipment and its sociopolitical significance varied greatly through the long history of the republic and the empire.

As a small Latin city-state, Rome relied on its land-owning citizens to provide soldiery for the defense of villages and crops. The soldier's arms and place in the ranks were based on five classes of wealth, each of these classes furnishing a certain number of companies known as centuries or hundreds. At the close of the monarchy there existed 210 centuries of infantry (21,000 men) and 18 of cavalry (1,800 men). Each citizen was liable to duty in the field between the ages of 17 and 46, but all citizens could be called to the defense of the city walls until the age of 60. There were three categories of mobilization: (1) the *dilectus* was the normal annual selection of the required number of soldiers for training and garrison duty; (2) the *tumultus* assembled all citizens liable to military service; and (3) the *evocatio* (actually a national religious rite) was used in times of great peril to bring the young, the aged, noncitizens and even slaves into the ranks as volunteers.

From the founding of the city until the close of the 2nd century B.C., Rome was served by a nonpermanent army of citizens. Armed after the Etruscan and Greek pattern, the Roman legion first copied the solid Greek phalanx, suitable to the plains of Latium, and used as its basic weapon the *hasta* (a thrusting spear) from which the heavy-armed infantry took their name *hastati*. Tradition assigns the first paid foreign service army to the close of the 5th century B.C. and the siege of the Etruscan city of Veii (*q.v.*).

As Rome expanded from Latium into the hills and valleys of central Italy, the phalanx, too unwieldy for fragmented fighting on broken ground, went into eclipse and the Romans began the long process of tactical and technical innovation which distinguishes their military history. Roman writers ascribe the legion, as a new tactical form, to the period of the Samnite Wars, but the transition from phalanx to legion must have been very gradual. Some modern scholars assign the tactical legion to reforms instituted shortly after the sack of Rome by the Gauls in 390 B.C. The original identifying mark of legion organization was the tactical subdivision into small groups, or maniples, of 120 men. But weapons changed as well: the *pilum*, a 7-ft. throwing spear with a soft metal head and shank replaced the *hasta;* small shields replaced the large, unwieldy Greco-Etruscan variety; the helmet became smaller with a metal crest and cheek pieces to protect the face; and, over an extended period of technological change, the famous legionary short, stabbing sword evolved.

The passages from Livy and Polybius which describe the legion of the middle republic are rather obscure. Apparently the maniples were arrayed in echelon on some checkerboard fashion. The first line consisted of the *hastati*, a purely honorary name since they were armed with the *pilum;* the next line was composed of the *principes*, another traditional name since these soldiers were no longer of the front rank or of higher property classification; in the third line—armed with a long spear instead of the *pilum*—were the *triarii*. The *triarii* probably stood three deep, the other maniples in files of six. Prior to the Punic Wars the Roman cavalry played no important role and the *equites* had political rather than military significance. During the early days of the republic the peacetime army normally consisted of two Roman legions plus two legions provided by the Italian allies (*auxilia*). These earlier legions varied between 4,000 and 6,000 men.

As Rome extended its hold on the Italian peninsula the rights and duties of citizenship expanded. Even after the bloody defeat suffered at Cannae (216 B.C.) Rome was able to call up 23 legions. In the course of the long wars of the 3rd century B.C. against Pyrrhus of Epirus, and Carthage and Macedon, the Roman armies became masters of the art of war, although often at the expense of severe reverses in battle. But the social, political and economic cost was high and the middle-class citizen and property owner, backbone of the legion, decreased in numbers and lost his civic-military status. Modern historians calculate that the Second Punic War cost Rome one-third of its citizens. During the economic depression and social upheaval which followed these wars, the annual levy of citizens for service in the army was retained only as a legal fiction. The citizen-soldier's oath of service, taken once each year, was replaced in the time of Gaius Marius by an oath binding the soldier to his commander for ten years or until such time as a consul gave permission for retirement. From about 107 B.C., therefore, the citizen-army of Romans was replaced by an army consisting of the landless proletariat and newly made Italian citizens whose allegiance was to their commander rather than to the Roman state and whose pay, in land grants or money, had to be extorted by the general from conquered peoples or the reluctant senate. The army was mercenary but not yet considered as having long-term service, since the economic organization to support such a permanent force was lacking.

Marius drastically reorganized the legion, numbering it at 4,500 and substituting a 600-man cohort for the old maniple in an attempt to meet the shock tactics of the Germans encroaching on the borders. The old division into *hastati*, *principes*, etc., disappeared and the patrician cavalry was disbanded. Marius gave the legions their famous eagles but the system of permanent numbers was not introduced until the time of Julius Caesar. With professional soldiers a higher degree of military training was possible. Regular drill with the short Roman sword was instituted on the model of the gladiator schools; a precise marching step was introduced even on route marches; logistics were regularized with two centuries per legion as service troops, a train of 3,600 mules for each consular army and a system of magazines along the great military roads. As Theodor Mommsen suggests, the army system created by Marius probably helped pave the way for the empire.

Augustus, founder of the empire, succeeded in restoring civil control over the Roman army but despite the experiences of the civil wars decided to retain the professional soldiery. He cut the number of legions from about 60 to 28, required permanent service for 20 years, and created a military treasury (supported by sales and inheritance taxes in Rome) to pay off veterans at the end of their service. The empire, therefore, began with the permanent, mercenary army. Under the empire the legions occupied home stations behind the long lines of fortifications (*limes*) which Augustus, Domitian, Trajan and Hadrian built to hold the barbarians at the limits of Roman power. But the legions still possessed the ability to deploy swiftly by marching at set pace with each man carrying about 40 lbs. of equipment, along the great system of military roads which knit the garrisons on the Rhine,

Danube and Euphrates together.

From the end of the 2nd century A.D. three main armies existed, in Gaul, Italy and the east. These armies were equipped from 34 great arsenal cities and were supplied by the provinces they guarded. Raised from barbarians on the borders and from the serfs provided by the great provincial landowners, the legions slowly lost their Roman character and the hard core of sturdy Italian citizenry. In the 3rd century A.D. sweeping military reforms were initiated by Diocletian. Flagging discipline in the heterogeneous legions was restored by a severe code of punishment; each legion was reduced to 2,000 men in an attempt to attain the mobility required in the border wars; and the strength of the army was raised to nearly 500,000—inducing a financial strain which contributed to the subsequent economic downfall of Rome. Constantine (*q.v.*) undertook the last major army reform, creating a mobile field army (*comitatenses*) as strategic reserve in the interior of the empire, and reorganizing the legions on the border (*ripenses*) as frontier guards.

When, in the 4th century, Constantine reunited the empire, military supremacy began the shift from Rome to Constantinople. This century may be said to mark a revolution in the art of war and the character of armies. In the preceding two centuries the saddle, stirrup, horseshoe and a new breed of heavy war horse had appeared in the Ukraine and on the Persian plateau, for the first time making it possible to mount a horseman wearing heavy armour and to employ cavalry as a shock weapon. This innovation spread to the Goths and Huns, then to the Roman armies which enlisted these barbarians as cavalry. The overwhelming defeat suffered by the legions of the emperor Valens at the hands of the Visigoth cavalry in 378 may also have had some influence. The heavy-armed cavalry, not the infantry, came to rule the battlefield and to dominate the armies of Europe for the next 1,000 years.

The Eastern Empire.—The fall of Rome witnessed the transfer of Roman traditions and institutions to Constantinople and the Eastern Roman empire. There, for 500 years, military institutions were the keystone of the struggle to stave off the barbarian floods sweeping into western Europe, Africa and the near east. From the 5th to the 7th centuries the Byzantine emperors relied on the navy and small, well-trained professional armies recruited from the barbarians and landless peasants. The theory of citizen service remained, but city dwellers, persons of property, artisans and the numerous clerics all were exempted from bearing arms. In Constantinople were quartered the *scholae*, or imperial bodyguard, recruited from the patriciate and mercenary soldiers, composed of both cavalry and infantry, equipped with heavy body armour, and garrisoned strategically to control the rulers of the eastern empire. In the border provinces existed permanent detachments of professional soldiers who were often settled on the land and of little use except as a kind of local police.

The nucleus of the field armies which campaigned with Narses and Belisarius (*qq.v.*) was the commander's bodyguard, organized much like the imperial bodyguard but attached to the person of the commander in the field. This professional army, despite its polyglot character, proved more than a match for the barbarians. Tactical innovation was introduced to meet each new enemy. Superior firepower in the form of portable missile-throwing machines compensated for their small numbers. This was an army based on heavy, iron-mailed cavalry wielding bows or lances; indeed, the emperor Maurice, reputed author of the *Strategon*, writes that the infantry had been so long neglected "that it does not exist any more." Rather than bear the expense of maintaining the large forces required to man the old Roman system of long walls, the Byzantines relied on a system of small garrisons strung in fortified posts (*castella*) along the main roads. The long-term professional army, expensively equipped and paid in gold, was always small in size. When Belisarius defeated the Persians in A.D. 530 his army numbered only 25,000, a small number from an empire of nearly 50,000,000 population.

The crises of the 7th century, arising from Arab and Persian expansion, resulted in military change. The invention of Greek fire (*q.v.*) gave the empire a formidable secret weapon which saved Byzantium on at least two occasions. The loss of imperial provinces in Syria and North Africa altered the strategic posture of the empire, pared away the useless border troops and led to the concentration of the army in Asia Minor. Political administration became subordinate to the military; a system of themes, or military districts, was created in which the *strategos*, or viceroy, controlled both army and civilian administration. This army was recruited from the settlers of the military and crown lands, which were granted the soldiers and their heirs in return for military service. The recruits provided their own horses and arms.

The new soldiery, well equipped and fanatic in the defense of the Christian faith, enabled the empire to take the offensive and double its extent during the 10th century. The victories of that era, however, were followed by a decline in military spirit. The pacific successors of Basil II feared the hereditary military caste and conspired with the great landowners and Byzantine patriciate to strip the soldier of his small holdings and special privileges. In the 11th century the Seljuk Turks began inroads into Asia Minor, slowly stripping from the empire those lands which had been the "soldier mines" of Anatolia.

During the span of life which remained to the eastern empire, the Byzantine armies were largely composed of Slav, Italian, German and Arab mercenaries. *See* BYZANTINE EMPIRE: *Defense*.

II. MEDIEVAL ARMIES

During the long centuries after the breakup of the Roman empire, various nations appeared on the scene and then disappeared. The Muslims roamed almost unchecked throughout the Mediterranean world, save for a number of unsuccessful sieges of Constantinople. In western Europe, the Franks utilized their inheritance of the Roman system to develop into the defenders of France against the Muslims. Later, under Charlemagne, the first signs of the feudal system began to appear. Knighthood developed in western Europe, sending many of its finest warriors to the eastern shores of the Mediterranean to fight the infidel.

In the final period of the crusades, the Mongol hordes of Genghis Khan and his successors flowed out of Asia until they were stopped near present-day Budapest on the Danube. There was little development of the military art during this period when heavy and light cavalry swept enemies before them. Only in England and Denmark did the infantryman retain a semblance of his ancient prestige.

Muslims.—Something new was added to the spirit of armies with the inclusion of a religious fanaticism. In fighting the Christian, the soldiers of Allah found their salvation, for "The sword is the key to Heaven and Hell" in the words of the *Koran*. Peaceful conversion to his cause having failed, the Muslim extended his religion by the sword. Hardy men, well disciplined and well led, they seemed to rely on brute force rather than upon newly conceived tactics. Wearing mail and helmets, but without shields, they brought terror to their ineffectual enemies by the sword, javelin, bow, dagger and scimitar. The last, a curved weapon, made of the finest Damascus or Toledo steel, was devastating in the hands of a believer. Besides scimitars, the infantry carried long, straight swords. The mounted men also carried straight swords, but relied mainly on their Arab lances, which were almost six feet long and tapered to long, slender points.

The Muslim forces lived on the country, enthusiastic to a point of foolishness over plunder. They were able to induce their conquered enemies to join them, either by force or through recruitment. Eventually, when they understood the value of a strong centre, like that of the legion and phalanx of old, they utilized European mercenaries for that purpose. The cavalry arm was reserved for Muslims.

For 100 years until the battle of Tours (A.D. 732) they were the scourge of the countries bordering on the Mediterranean. Believing that the time had come after a succession of triumphs to add Europe to the caliphate, they crossed the Pyrenees with 80,000 men. Plundering and burning, they came to Tours where Charles Martel and his Franks prepared to fight in defense of

Christendom. In six days of maneuvering, the Muslim cavalry found its equal in the Frankish infantry. When the tide was turning in favour of the Muslims on the afternoon of the seventh day, rumours that the Frankish cavalry was in the rear of the Muslims sacking their camp with its plunder, resulted in some of the Muslims turning from the main objective. Martel won a tremendous victory, in what is considered one of the decisive battles of history. The Muslim threat against Christendom was never again to reach so far into Europe.

Feudal System and the Crusades.—Under the Franks, a system of landholding and military service grew up in France which was called feudalism. The conquerors became the lords; the conquered, the serfs. The lords were the primary warrior class, assisted by some partially armed serfs and by unarmed serfs as servants. Because land was inherited, the serf could not rise in the social scale. The lord thereby commanded because of his position, not necessarily because of ability. Furthermore, land being broken up into small areas, each lord became a law unto himself, unless he owed allegiance to a higher lord. There was a certain hierarchy among the lords, up to the king, the lesser being a vassal to his superior. The vassal had to furnish a certain number of armed men to fight in his lord's service for 40 days a year. As a result, warfare was confined to short campaigns and often to periods of the year when men could be spared from the fields.

Forty-day army duty was insufficient for the long tenure of the crusades and other campaigns, resulting in the return of professional armies. The hiring of professional soldiers was made possible through the alternative permitted to vassals of sending gold instead of armed men when called upon for their levy.

All eyes were upon the individual knight. His exploits as an individual, even as a knight-errant, were sung in song and story. The personal element was inimical to discipline and teamwork, and prevented the creation of a chain of command. Serving the lordly caste were the despised and poorly armed foot soldiers. Their part in battle was negligible, the poor knaves having to fend off the charges of even their own knights in their efforts to do battle against the opposing knights. (*See* KNIGHTHOOD, CHIVALRY AND ORDERS.)

The crusades (*q.v.*), seven in number between A.D. 1096 and A.D. 1279, were fought by the heavily armoured mounted knights, accompanied by light-armoured feudal tenants, and supported by serfs, retainers and a few mercenaries as foot soldiers. Out of these individualistic endeavours, in the service of particular lords rather than of nations, there were no developments from a military standpoint. The faults of the crusaders, of mediocre generalship, lack of coherent action and failure to establish proper supply bases pointed up the need for organization of armies.

The crusades never achieved their objective of liberating the Holy Land from the Muslims. However, partially because of the death of many nobles, the system of landholding was gradually abolished, as was serfdom. From the military mistakes of earlier crusades, there developed better leadership in that of Frederick Barbarossa and Richard the Lion-Heart. Armour proved too unwieldy and hot in tropical lands, and the importance of supply bases became apparent to all. Furthermore, the crusaders learned much about the attack of fortifications from their experiences. During the later crusades, warfare in Europe began to draw the attention of the knights, as did a new menace from the eastern steppes. Another wave of barbarians threatened Christendom at home.

Mongols.—During the 13th century Genghis Khan and his hordes swept across Asia and into Europe, until they had conquered half the known world. Known as the Golden Horde (*q.v.*), the Mongol invaders were a well-disciplined, highly organized and trained army. Leadership was superb and youthful, such men as Chépé and Sabutai rising to high command by the age of 25.

The Mongol army, practically all cavalry, was organized on the decimal system. The touman of 10,000 horsemen was the largest independent unit, corresponding to cavalry divisions of later centuries. An army was usually composed of three toumans, each with ten regiments of 1,000 men each. The regiment had ten squadrons, each of the latter with ten troops of ten men.

Their battlefield maneuvers were regulated by black and white flags, thus eliminating oral or written orders. Mobility and speed were main factors as well as the shock effect of the first two of five lines of horsemen. Horses and men of the first two lines wore leather armour and fought with sabres and lances. The following three lines were armed with javelins and bows but were unarmoured.

From a military standpoint Genghis Khan was a master strategist and tactician. He knew how to organize an army, how to use spies for intelligence and how to propagandize enemy peoples. In battles like Bukhara and Gran, the Mongol army exhibited a capacity for synchronizing the arrival of different columns at a rendezvous point hundreds of miles distant which would be brilliant even in the age of radio and telephone. Again and again Mongol armies under a number of different leaders used ruses to win victories, just as in many of their battles the leaders showed a fine strategic sense in the selection of distant battlefields. A similar capacity won for Napoleon much of his fame in his Italian campaigns. Though the high point of the Mongol advance was attained at Gran in Hungary and resulted in the annihilation of the Hungarians, the Mongols turned home. The breakup of their control at home and competition for power upon the death of the leaders, prevented the Mongols from attempting to overrun Europe.

End of Feudal Armies.—In the long period from about A.D. 1300 to the Thirty Years' War (1618–48), feudalism came to an end. Cavalry was replaced by infantry. There was almost continuous warfare in Italy, Spain and the Netherlands, and the Hundred Years' War between France and England from the middle of the 14th to the middle of the 15th century.

During the later middle ages the warfare of the knights in Europe was of mixed character, some battles being fought by the armoured knights on foot, others by infantry drawn from the burghers of France, who were successful against mounted knights. The burgher militia of the cities of Flanders, numbering 20,000, defeated a feudal army of 50,000 at Courtrai (A.D. 1302). The Flemish foot soldiers were successful partly because of their own circumspection in placing ditches to their front and flanks, and partly because of the false sense of chivalry of the French in maintaining that they must attack straight ahead in an arrogant but futile dash against the main strength of the burghers.

The crossbow was becoming the main armament of the foot soldiers, despite the fact that it had been banned as a deadly weapon by a Lateran council in A.D. 1139. Throughout Europe the crossbow became the main weapon of armies, along with the pike. But it was never accepted by the British, who preferred the longbow.

In England the armies were turning from feudalistic practices through a long series of legal acts. For instance, the practice of hiring foreign mercenaries common in the 12th century had been checked by the Magna Carta. A system of payment for military service became accepted, mostly because of the realization that feudal service had yielded a poorly trained and undisciplined mob looking forward to release after 40 days. Military service gradually became a duty insisted upon by all freemen, and the armies drew their foot soldiers by levy upon the counties.

Two developments stand out in this period of warfare—new weapons and mercenaries. The English longbow dominated the field of weapons for more than a century even after the appearance of the first firearms. The longbow, about five feet high, shot arrows a yard long with deadly accuracy up to 200 yd. The fact that it could shoot as many as 20 aimed shots a minute made it superior to the crude firearms for a long time. The longbow made its dramatic debut on the continent when English yeomen stemmed the charge of the French knights at Crécy (1346). Their volleys darkened the sky and their arrows found their mark even through armour.

Though the longbow defeated the French cavalry, it did not of itself bring back the supremacy of the foot soldier. Bowmen were dependent upon the weight of massed infantrymen to defeat cavalry. It took the Swiss pikemen to confirm the decision in

favour of the foot soldier; the pike brought about the return of the Greek phalanx in a Swiss counterpart, and in the later Spanish square.

The cycle had come full turn. The mobility developed by the cavalry for 1,000 years was sacrificed for firepower and the weight of mass manpower. For three centuries the variations in the Greek phalanx won victories in Europe. The Swiss usually could not afford horses and armour; they won victories through the homogeneity of their solid mass. By constant drill they were able to advance and to maneuver in a limited fashion in their tight formation. Ahead of them were their pikes which became the scourge of mounted men. Other nations copied the Swiss, or hired Swiss mercenaries to fight for them.

In time the Swiss phalanx gave way to the Spanish square. This facsimile of the phalanx was a square with 50 men on a front and in file. Its claim to domination of the battlefield came from its combination of the pike with the sword and musket, all placed for greatest tactical advantage in the human mass. Behind the front-rank pikemen were several lines of swordsmen, ready to cut down the enemy pikemen brought to bay by their front ranks. At the corners of the formation were a number of musketeers. After a single laborious shot, the musketeer filed to the rear to reload. In support of the square were cavalrymen armed with pistols. They, too, presumably followed the role of the musketeers, galloping to the front, firing and then going to the rear to reload.

During three centuries of this period, war became more professional than at any time in history. Free companies were formed of men whose business was to fight, for pay and plunder. This "trade guild" of war was brought into existence by the fact that burghers were unwilling to undertake wars of aggression. Hired by princes as companies already organized, unlike mercenaries of previous days who were hired individually, they gave to their effort a certain experience and discipline. However, as professionals, they showed a disinclination to bloodshed, and inconclusive campaigns were the rule. Undoubtedly they were the best troops in existence but lack of a cause in their fighting made them a poor substitute for the citizen-soldier of earlier times. Their one contribution to the development of armies was their organization. Leadership among small units assumed an importance which continued to modern times. Furthermore, some authorities aver that the free companies set the pattern for the professional soldier, who made his career in the art and science of warfare. A glimpse at the various free companies by nationality is of interest as a preview of the national armies which stemmed from them.

Condottieri.—The original free companies were the Italian condottieri, translated contractors, in the meaning that leaders contracted to furnish disciplined, experienced organizations to fight for princes in return for money. The condottieri were so skilled that they were able to put on a long-drawn-out campaign with the casualties being only those unfortunate victims of accidents incident to the movements of large numbers of men. Machiavelli reported some of the condottieri battles in Renaissance Italy with profound disgust. In several battles only a few deaths occurred, and the sole winners were the condottieri who bled Italy of gold. There was a tournament spirit about free-company battles. Emphasis was on showmanship rather than the creation of new tactics. Machiavelli believed that medieval warfare was obsolete and that it should be replaced by national armies and new tactics. (*See* CONDOTTIERE.)

Swiss.—In contrast to the condottieri were the Swiss mercenaries who proved they were worth their hire. Again and again they fought fiercely and capably even though motivated only by profit. In the late 15th century the Swiss made their reputation in a series of three decisive victories over Charles the Bold, duke of Burgundy. Subsequently, the Swiss were acknowledged champions of Europe. Despite their successes, they sought neither to change the methods of warfare nor to conquer new territories. Gold was their one desire. The spirit was communicated to the succeeding generations of Swiss to the end that every boy yearned only to be trained as a soldier so that he too could enter the state profession and courageously earn the profit due him.

This predilection for paid warfare was exported across the borders into Germany, where the competing free companies became known as *Landsknechts.* While at first clumsy in their imitations of the Swiss phalanx, they became in time hardy infantrymen and innovators in tactics and in the use of the new firearms. Like the Italians and Swiss they were freebooters and blackmailers whose business of fighting became a paltry and sad one. The *Landsknechts,* like other free companies, developed organizational forms, followed the colours of a leader and contributed something of the regimental spirit with its arbitrary customs and manners which became tradition in latter day armies.

Spanish.—The Spaniards themselves never succumbed to the lure of service in free companies. However, during the age of Charles V in the first half of the 16th century, Spanish armies were made up largely of non-Spanish mercenaries, particularly German, Italian and Walloon. Charles outdid Charlemagne in the extent of his conquests. His army, though largely mercenary, was led by Spaniards and a fine strain of Spanish blood filtered throughout. A spirit of patriotism, of loyalty to Charles V, was infused into the entire army.

It was an intelligent army, capable of appreciating the requirements which new weapons made on tactics. In the Spanish square, described above, the old (pike and sword) was amalgamated with the new (the arquebus) for the first time. The latter, the first real hand gun, had a fuse which was brought against the powder in the priming pan when activated by the pressure of the trigger.

Organizationally, the Spanish contributed to the development of the regiment with their *tercio* composed of 12 companies of 250 men each. From their battle experience the arquebusiers were increased until they equalled in number the pikemen in the *tercio.* The colonel of this tactical unit was assisted by a sergeant major, an adjutant, a quartermaster, a chaplain and a medical staff.

Dutch.—The Spanish phalanx met its defeat at the hands of the Dutch patriots, organized for victory by Maurice of Nassau. His constant drill of the sturdy Dutch citizen-soldier brought into being a force which maintained its ground against the best Spanish forces in the years preceding the Thirty Years' War. In the evolution of armies the Dutch passed on the passion for drill and their addiction to the science of warfare. The ground was being laid for the creation of national armies and for greater attention to maneuver and to fortification.

III. DEVELOPMENT OF STANDING ARMIES

The Thirty Years' War between the Protestants of the north and the Catholics of the south was a turning point in methods of warfare and particularly in the organization of armies. The free companies of infantry armed with pike and musket had ended the long cycle of cavalry supremacy. Armies were again modeled on those of Greece and Rome, with cavalry supporting the infantry. Armour had disappeared, mainly because it was not proof against firearms. It constituted a hazard because it made the wearer ungainly and, when struck by ball, tended to splinter. Leather boots and buffcoats replaced armour for protection. Shock tactics were replaced by firepower tactics; the lance by the musket.

Gustavus II Adolphus.—The improvements in tactics, weapons, organization and administration were brought together into a new military system by Gustavus II Adolphus (*q.v.*), king of Sweden. From its first battle at Breitenfeld in 1631, the army of this champion of Protestantism fought a series of six campaigns during the next 16 yr. As a result, Gustavus earned the right to be called the father of modern war, even though he was killed at Lützen (1632) while leading his victorious troops.

Before his campaigns, he forged a national standing army in Sweden, a development common to Europe for the next century and a half. All men over 15 years of age, with some exceptions, were liable for military service. While this draft of manpower was not sufficient in a country with the small population of Sweden to meet the army's requirements, he utilized the Swedes for the hard core. Mercenary troops, Scots and Germans, augmented his infantry strength, but even these men came under the spell of his leadership and his requirement that war be conducted within the bounds of Christian teachings.

Utilizing the draft of manpower, Gustavus developed a regular

army organization based upon a company of 150 men, 6 files deep. Four companies comprised a battalion, and three battalions a brigade. Recognizing the fact that firearms could be developed to dominate the battlefield, he brought about the invention of a lighter musket improved to permit faster loading. He also reduced the weight of the musket by replacing the heavy iron fork by a thin spike, which served as a rest for the musket. His men used paper cartridges containing a prepared charge of powder and ball. When the Swedish soldier reloaded he bit off the end of the cartridge and pushed it home with a ramrod.

Increased firepower was also assured by the inclusion of artillery as a part of the army, about six cannon being furnished for every 1,000 men. The cannon were four-pounders drawn by one or two horses. The artillery was made very mobile in order that it could operate in support of the heavy cavalry. With this increased firepower Gustavus worked out tactics which included the shock of a cavalry charge in conjunction with infantry and field artillery. This combination of arms was the first known in modern warfare. In addition Gustavus developed what became known as linear tactics, employing two lines of troops and a third line as a reserve.

In battle he formed his army with the infantry regiment in the centre and with cavalry on the front. The cavalry regiments attacked with speed but at a trot, which was a departure from the idea that cavalry charges should be at a gallop. As the three ranks of cavalry advanced, the front rank fired its pistols and after firing charged with drawn sabres. The infantry meanwhile moved forward on foot, stopping now and then to fire their weapons. The front rank would kneel and the other two ranks would fire from a standing position. By such tactics Gustavus defeated all the troops that he met and in time his tactics and organization were imitated by all the armies in Europe.

Before his time artillery, cavalry and infantry operated more or less independently. Gustavus co-ordinated their activities by using his artillery first to soften up the enemy, followed by cavalry charges which cracked the enemy's resistance. The infantry was then used to mop up the disorganized opponent.

As a further contribution to warfare, Gustavus, on the basis of a Dutch engineering system, utilized field fortifications as a normal part of his tactical dispositions. He organized units of sappers to dig troop entrenchments and cannon positions.

Cromwell.—In contrast with other European nations England had little military tradition. The navy was its chief reliance. In the constitutional quarrel in England, Oliver Cromwell (*q.v.*) fashioned his "new model" army on that of the Swedes. There was little about his tactics or organization which was an improvement upon that of Gustavus; rather, Cromwell's army was new only in its religious fervour. He instituted the idea of a basic training period of several months during which the men were drilled hard and introduced to an iron discipline. He dressed the men in scarlet coats with facings bearing regimental colours, a uniform which became traditional in England. Like the Swedes, Cromwell's men were armed with muskets and pikes. However, the musketeers were armed with the old matchlock which took some 95 motions to load and fire. Even with well-drilled and disciplined troops the slow rate of fire made it difficult to repulse cavalry charges.

The example of Cromwell disappeared in Britain, though later Frederick the Great introduced similar ideas in Prussia.

French.—During the latter part of the 17th century, Louis XIV was assisted by a number of specialists whose names became famous in the art of warfare. The minister of war François Michel Le Tellier Louvois began a reorganization of the army which included inspections of the troops by a separate group of administrators. One of the inspectors Jean Martinet left his name as a synonym for severity of discipline. Promotion was made on merit, thus eliminating the former practice of purchasing commissions. Battalions were organized into permanent regiments under designated commanders. Lastly, he brought into practice the method of taking formation at a command rather than the laborious practice of having the sergeant major place each man.

Another of Louvois's contributions to administration was the creation of a quartermaster department. He trained a staff to supervise the procurement and transportation of supplies. His reforms, the first in this field in history, included the improvement of roads for the movement of supplies and the establishment of storage areas where food and ammunition could be strategically located. The latter device made it possible for troops to be maneuvered for the sole objective of winning battles instead of fighting battles where the troops could live off the country.

In another long-neglected field Louis XIV was fortunate enough to obtain the services of a young engineer Sebastien Le Prestre de Vauban who invented a systematic method of attacking fortresses so successfully that it governed siegecraft for the following century and a half. His method of attack was known as the "approach by parallel line." His first move was to surround a fortress and cut off its communications from the outside. Then concentrating upon one side of the fortress he brought up artillery to within 600 yd. of the walls. Behind the guns he dug trenches parallel to the fortress walls for the protection of the infantrymen so that they could defend the batteries from capture should the defenders make a sortie. Meanwhile approach trenches were dug in zig-zags so that the men would be safe from the gunfire from the fortress.

From the approach trenches, a second parallel nearer to the wall was dug and the guns moved forward. Normally a third parallel was sufficient to bring the attackers to the walls of the fortress. The artillery from this vantage point could fire directly at the masonry of the scarp. Once that was breached, fortresses usually surrendered. There was nothing infallible about Vauban's system; it could be varied depending upon the type of fortress under attack. Oddly enough fortresses were classified according to their expected period for holding out without relief. Vauban's methods made military engineers an important part of the new armies.

Despite the improved administration and methods of siege warfare introduced by the French, the army was undisciplined, poorly paid and in due course often defeated. The day came when the French army assisted the revolutionaries against the king.

Frederick the Great.—Frederick the Great is remembered more for his tactical skill and iron discipline than for the strategic employment of his army. Generally he improved upon the organization, equipment and training of the armies of his predecessors, and most importantly brought mobility to the modern battlefield. His military successes were in large part the result of his indomitable will, great energy, unwavering control of his men and his position as both king and commander.

From the experiments of the previous century he concluded that infantry could be developed to deliver heavier fire while moving forward. His ideas of fire and movement were maintained through World War II. With a thin line of infantry which deployed from a marching column at about 1,000 yd. from the enemy, it advanced in parade-ground formation, marching in step to music. The two or three long lines, each three ranks deep, held their fire until they were about 100 yd. from the enemy. The troops would deliver volleys in quick succession and reload while advancing a few paces. The final assault was made with a bayonet which had been developed by Vauban. Supplementing his infantry were three kinds of cavalry, called the cuirassiers, dragoons and hussars. The last named were the light cavalry used for scouting; the dragoons were mounted infantry using their horses as a means of getting rapidly from place to place; the cuirassiers were the heavy cavalry used in conventional manner on the flanks of the advancing infantry. (*See* CUIRASSIERS; DRAGOON; HUSSAR.)

Frederick initially was slow to use artillery. However, in time he saw its advantage and placed his batteries on the wings in the front of the line. As the infantry was depleted in successive campaigns, Frederick came to depend more and more upon his artillery.

In addition to the thin-line tactics, Frederick also introduced, as a result of his drill formation, a maneuver of wheeling his line to change direction. As a further development he reinstituted the oblique tactics of the Greeks in which he placed his

troops in echelon so that he refused one flank of his army to the enemy.

Frederick's method became the basis for the organization of armies for the next century and a half. Imitation of Prussian drill, uniforms and even hair powder spread throughout Europe and to America. Baron von Steuben, as Washington's drillmaster, was clever enough to realize, though, that the Prussian system was best adapted to private soldiers who waited for commands rather than for independent colonists fighting for their independence.

American and French Revolutions.—In the development of tactics during the 18th century the light skirmish line of the American frontier riflemen made its imprint upon armies. The thin line was so successful over the British heavy infantry in mass formation that the nations of Europe began to consider this improvement over Frederick's method as worth imitation. The skirmish line became a very loose formation and mobile since the men were burdened with less equipment. It was a great change from the Swiss phalanx and the Spanish square, increasing the infantry's flexibility in battle.

The development of standing armies was a great change from the previous period when mercenaries made up most of the armies. Standing armies brought into being a regular system of recruitment, which previously had often been impressment. Soldiers were paid, and served for long periods. Officers were appointed and the professional military man was more aware of his duties to the state which were written down in what became known as the "Articles of War." Uniforms became universal and the relationship of the soldier and the civilian became more distant.

The armies themselves remained generally under the strength of 100,000 men. The units such as regiments and battalions became tactical as well as administrative units. Because of tactical requirements, drill became more severe and discipline harsher. Warfare itself was fought along conventional lines and the troops no longer plundered the countryside as the free companies had done in the past. Happily too the people of that time were as a whole less affected by war. It was the king's business and fought by professionals along regularly prescribed lines. Out of this orderly warfare of the standing armies came the next great development, that of the nation in arms. The middle-class revolt as a social phenomenon brought about a great change in armies.

The French Revolution produced the new soldiery for the Napoleonic triumphs but into their hands were placed a new mobile, heavier artillery, a convenient divisional organization tailor-made for large armies and a general staff to control the armies. Napoleon an artillery officer, reaped the benefits of these developments of his French predecessors—Jean Baptiste de Gribeauval, Marshal de Broglie (Victor François, duc de Broglie), and Pierre-Joseph de Bourcet. Their developments occurred during the period between the close of the Seven Years' War and the French Revolution.

Napoleon said later that "The cannon has made a complete revolution." Guns had been heavy, unwieldy and insufficiently mobile to accompany armies readily. Frederick the Great had depended upon two 6-pounders and one 7-pounder with each battalion. Gribeauval, determining that by reducing the charge he could increase the range of the projectile, made the guns lighter and more mobile by reducing the thickness of the walls of the tube. His big guns, 12- and 18-pounders, were able to accompany the army, and even his 4-pounders could fire three or four times faster than the old guns. Artillery tacticians then developed the use of these new guns to accompany the armies and to blast a path for the infantry by knocking out enemy strongpoints.

De Broglie was the initiator of the articulated and mutually supporting divisional system of organization, two or more divisions being integrated into a corps. Washington had organized the American armies in this manner, and even when they were separated by several days' march, arranged that they could be readily united for battle.

Lastly, a staff system was developed in France as well as in Prussia. Bourcet had proposed that a staff corps be created to produce maps, make reconnaissances and to prepare war plans. The French system had previously developed a need for inspectors, quartermasters, ordnance and artillery staff officers. To meet the demand for trained staff officers a staff school had been established and was producing trained men before the Revolution. Though a number of the royalist staff officers emigrated at the beginning of the Revolution, a strong nucleus remained. (*See* STAFF, MILITARY.)

IV. THE NATION IN ARMS

The French Revolution was six years old before Napoleon became prominent. One of the greatest changes in the development of armies during this period occurred in 1798. The professional soldier was succeeded by the citizen-soldier fighting out of a patriotic spirit and with an enthusiasm unknown to the professional armies. Desertion became less common. Fighting moved into open formations similar to those of the American colonial soldier.

Unable to stop the advance of the Austrians and Prussians, the republican government of France conscripted 300,000 men of the national guard in Feb. 1793, and later made a general levy of all able men between the ages of 18 and 25. There were no exemptions except for the disabled, and punishment was severe for those who resisted service. The nation's call to arms produced in a few months more than 1,000,000 men, a number unknown in armies after the days of ancient Persia. That draft of manpower was a forerunner of the almost universal dependence on conscription as a basis of recruitment from that day forward. (*See* CONSCRIPTION.)

This social phenomenon of the nation in arms induced tremendous changes in warfare. The tactics and strategy of the professional armies of the past needed revision to meet the new requirements of the conscripted armies. Another feature of the nation in arms was the appeal to patriotism and to the individualistic spirit of each citizen. The army was made up of men from all strata of society. The old differences between the nobility and the peasantry were broken down. Napoleon himself had risen from nowhere to become a general, and out of his experience he told his men that every man carried a baton in his knapsack. There was no insistence on noble ancestors, and many of Napoleon's marshals would never have been more than sergeants in the old French army.

Napoleon.—In 1795 Napoleon first came into favour with the Republican government. His activities as an artillery officer in the regular army had brought him into discredit and he had been dropped from the rolls. In 1795 he was in Paris when the Royalists attempted to overthrow the government. In command of the army in Paris he put down the uprising and thereby won himself the command of the army in Italy. From that day until the battle of Waterloo the history of warfare and of armies centred around Napoleon.

As an artillery officer he knew how to use that weapon. He brought together the infantry, cavalry and artillery into the division. The divisions in turn were drawn together into army corps which varied in size and organization. His new tactics utilized the drafted men who became veterans in the shock of infantry attack together with artillery fire. The usual tactic was to feel out the enemy's front to find his weakest point. Weight of fire and men then were brought to bear to make a breach.

In this strategy Napoleon was a master at bringing his troops together before a battle on ground most often of his own choosing. Flank attacks and envelopments were common to most of his battles. Once the enemy was upset he used his reserves for a decisive thrust. Simplicity was common to his methods.

In the open order fighting Napoleon formed his infantry in three ranks and the cavalry in two. However, he was an exponent of flexibility and broke up his units into small columns for maneuver and assault. While his troops were numerous he made great use of individual initiative in utilizing small groups against enemy masses. As the calibre of his men deteriorated and his army became a polyglot mass of all nationalities of Europe he increased the proportion of artillery and concentrated his troops into mass

for attack. His weapons were similar to those used in Frederick's army, but the greatest improvements had been made in artillery. He put great trust in the bayonet saying "it is the arm best suited to the French soldier." From 1796 through 1806 Napoleon won a steady succession of victories in northern Italy, in Prussia, Austria and Spain. (*See* NAPOLEON I; NAPOLEONIC WARS.)

Armies of Liberation.—After the defeat at Jena, Prussia was compelled by a treaty of peace to limit its army to 42,000 men. However, by passing the men through the ranks as soon as they had been trained, new recruits were constantly added to the army and the reserve was filled with trained men. Prussia too undertook the conscription of its manpower. A new army under Gerhard Johann David von Scharnhorst (*q.v.*) arose from the ashes of Jena, an army totally different from that left by Frederick. The Prussians maintained a few officers and noncommissioned officers as a permanent cadre to conduct the training of the conscripted army. The first meetings of the new Prussian army with Napoleon ended in defeat, for Napoleon was at the height of his soldierly skill, but the Prussians adopted the open-field tactics of the French, and in time managed to win in combat against all the French leaders except Napoleon himself. The real triumph for the Prussians was Waterloo, where the training of Scharnhorst decided the conflict in favour of Gebhard Leberecht von Blücher (*q.v.*). Of the other armies opposing the French during the Napoleonic era those of Austria and Britain were designed much like the French army itself. Wellington commanded the British army conscripted in the same manner as the French. The conscript system of recruiting troops became common throughout Europe even in Russia, where there was a mass levy of peasants to fill the ranks of the army. (*See* WATERLOO CAMPAIGN.)

1815–70.—After Napoleon's defeat a military peace settled over Europe and America for several decades. Long-service armies proved themselves to be the best form of military protection for the countries of Europe and for use in the colonies. All attention in the military field was concentrated upon a study of Napoleon. Every commander read of Napoleon's battles and of the reasons for his decisions. Two military scholars Baron Antoine Henri Jomini and Karl von Clausewitz (*qq.v.*) made exhaustive studies of Napoleon's tactics and strategy. The fame of both became known in all armies and eventually Germany developed several leaders who utilized Clausewitz' studies as a basis for their strategy against France. His book, *On War*, remained a textbook for military leaders for a century. He set forth the relationship between the army leaders and the leaders of the state in clear-cut fashion. He discussed at length the first rule of war, that of gaining decision in battle.

The first half of the 19th century saw little change in the organization or administration of armies. The big changes came in technical improvements. The industrial revolution had a great influence upon the technical equipment in armies, though development was slow as there were no large scale conflicts requiring the use of an industrial potential. Muskets were equipped with hammerlocks and percussion caps. There were many new inventions in firearms, but in most cases the new improvements were tried out in sporting guns before being used in the army. (*See* SMALL ARMS, MILITARY; ARTILLERY.)

The advance in technology resulted in the introduction into armies of inventions such as steam engines and later the telephone, wireless and bicycles. To use these inventions properly the number of technical troops in armies increased greatly. The division organization was expanded to include more technical troops while other technical units were attached to the headquarters of corps. Another development of the 19th century was that of the staff. Prior to that time commanders had generally been their own staff assisted by a few assistants, spies and quartermaster officers. After Napoleon's time the Prussian staff system which was built upon the French became the model for the nations of Europe, certain adaptions being made to fit the individual situation. (*See* STAFF, MILITARY.) The first military test of the industrial revolution was the American Civil War. Not only did production become important but the railway was used to transport troops more speedily than at any time before in history. (*See* LOGISTICS.)

American Civil War.—This tremendous struggle was the first great war of the modern period where industry and transportation played a decisive part. The tactics and weapons are still readily identifiable with those of World Wars I and II. Compared with previous armies and the areas in which they operated, the Civil War was a gigantic conflict. The theatre of operation extended 1,500 mi. on its long axis and 800 mi. on its short axis. The railway and telegraph became of primary importance in the handling of the large number of troops in this war. Besides the first battle between ironclad warships, there was the first recorded use of the submarine and of the electrically exploded torpedo. Metal cartridges were invented for the breech-loading repeating rifle; military observation balloons appeared along with the land mine and hand grenade.

The moral question of slavery was one of the issues in the conflict. As a result a greater proportion of the population turned out to fight than had been the case in previous wars. The South with 9,000,000 had an army of as many as 500,000 while the North with 22,000,000 inhabitants produced an army of a maximum strength of more than 1,000,000. Apart from a few thousand professional soldiers and some draftees both of these forces were mainly volunteers. The majority of the commanders on both sides were products of the same schooling at the United States Military academy and as a result the organization of the army on each side was almost identical. The infantry regiments numbered about 1,000 men and consisted of ten companies. There was a general use of skirmish lines, and the attack formation called for each regiment to advance on a two-company front. As the war continued a number of revisions were made such as the advance by rushes, half the men firing, while halted, the other half running forward simultaneously. Cavalry was of great importance in the war, and the regiment was approximately the same size as that of the infantry. Normally there were 12 troops each numbering 70 men. The cavalry normally fought dismounted under Gen. Philip Sheridan in the Northern army while the Southern cavalry under Gen. J. E. B. Stuart and Nathan B. Forrest fought on horseback. The artillery battery composed of six guns was employed separately at the beginning of the war. Later they were organized into brigades of five batteries, a system which permitted heavy concentration of artillery fire at key points on the battle front. There was no general system for training the troops. Most of them obtained their training at the whim of the locally appointed officer. However, there was a certain amount of standardization in drill, markmanship and tactics since there had been a general publication of these matters in the *Field Service Regulations*.

Staff systems were greatly developed during the war, there being in each army staff officers for duties such as quartermaster, inspector general, adjutant general and others. Greater attention was paid to the medical care of the troops than at any time previously and nursing by women was a great contribution to the relief of the wounded; nevertheless, the war cost 500,000 lives. Tremendous strides were made in military engineering because of the demand for bridge building and for entrenching and mining. River crossing in the huge area of operations was a continual difficulty to both forces. Pontoon bridges were manufactured of both wood and canvas, the pattern being set for such bridging for the next 75 years.

Hasty field fortification was another endeavour which became a normal battlefield task for the first time in warfare. Almost without instruction the U.S. soldier began entrenching and constructing obstacles in preparation for battle. The work was crude and improvised but the results were effective. Another form of protection was the log breastwork which enabled the men to load their muskets in a standing position.

The importance of railways in the Civil War was evidently due to the size of the combat area. The armies could not live off the country and were dependent upon supplies sent by railway, often over long distances. The railways were few in number and most of them single tracked with poor roadbeds. Also for the first time the operation of military and civilian traffic over the railways

became a matter of concern to the government. An army came to realize the necessity for traffic other than purely military. Steel and coal had to be kept moving to provide materials to fill the demands for munitions. As an instance of the importance of railways to military transportation, a movement of reserve troops by the union army at Chickamauga involved 23,000 men with artillery and supplies over a distance of 1,200 mi. in seven days. Though it involved few changes in organization and training, this war emphasized that industrial revolution had taken its hold on armies and their tactics. (*See* also AMERICAN CIVIL WAR.)

The lessons of the Civil War made only a small imprint upon the Germans and none at all upon the French when they went to war in 1870.

Franco-German War.—Bismarck's policy of blood and iron brought on a war with France in 1870, the first major conflict in Europe since 1815. Both armies had been trained under systems which had become obsolete. The German doctrine was one of offensive while the French had been trained to use their long-range rifle on defensive until an opening appeared for an attack. The Germans were recruited under much the same system as Scharnhorst had used in 1807, all physically fit German men being liable for service at the age of 20. The enlistment was for three years after which there were varying periods of duty in the reserve. In France the service was five years in the regular army followed by four in the reserve. Each conscription group became known as the class of a certain year, usually the year when contemporaries came of military age. Experience in the battle of St. Privat indicated to the Germans that their attack in company column laid them open to the effective fire of the French weapons. The regimental attacks failed when, about 500 yd. from the French position, their cohesion was destroyed by the accuracy of the French rifle. As a result of this experience the Germans quickly adopted the line of skirmishers employed by the Americans in the Civil War and also the system of advancing by rushes. Armed with breechloaders, the men not advancing were able to fire from a prone position. The French infantry weapon was the chassepot rifle, effective at 1,300 yd., which was almost twice the range of the German needle gun. Moreover the French rifle was superior in every other way to the German rifle. The Germans, however, overcame the single French advantage of the rifle by the weight of their superior forces, by their artillery and by the adoption of the wide-open tactics of the skirmish line. The Franco-German War (*q.v.*) was, however, only a prelude to the much greater conflict between these two nations in 1914. Preparations began almost at once for a re-enactment of the war, but by 1914 many other nations were involved in what became a world war.

V. DEVELOPMENTS PRIOR TO WORLD WAR I

The German system became the model for the armies of Europe and also of Japan. The success of the German army over the professional long-term army of the French gave a pattern to military organization for the succeeding 40-odd years. Wartime conscription was replaced by universal liability to serve in peace as well as war. In Germany every man was required to perform active service for three years beginning at age 20. After he had completed his active service he was placed in the reserve where there were occasional training periods. At 27 years of age he became a member of the national guard where there was less frequent training. Finally until he was aged 50 he was a member of the inactive reserve but still available for special duties. This system required service of every man and did not, like conscription, make service a matter of drawing lots or of paying someone else to perform this duty.

Size and Organization.—European nations increased the size of their peacetime armies to some extent during this period, but the great increase was in the military potential in manpower. Germany, for example, doubled the size of its peacetime army from 400,000 to 850,000, but had in addition more than 4,000,000 trained men. France kept pace with Germany with similar strength in its army. However, with a smaller population France could not afford to exempt certain groups from military service. So universal was the French military service, that even medical students and priests served in the ranks as common soldiers. In France, service in active forces as well as that in the reserve was extended beyond that of Germany so that France's strength might be comparable. In Austria-Hungary the active army was 500,000 in strength with a potential of more than 2,000,000 trained men. In Russia only a small proportion of the population was touched by compulsory service to produce a regular army of 1,500,000 men and a trained reserve of 6,000,000. In the smaller states of Europe the armies followed the pattern of their larger neighbours. Continental Europe had become an armed camp.

Only in Great Britain and the United States was compulsory service not adopted. It was in the tradition of these people to maintain small armies recruited by voluntary enlistment. Moreover, Britain was essentially a sea power and the navy took first priority on manpower. The army's principal task was to garrison the colonial possessions with small units of troops. Strangely enough the voluntary system with a long-service army was in some respects relatively more expensive for a nation since the men had to be better paid and the conditions of service made more attractive.

Two great changes occurred in the organization of armies during this period: the development of the three fields of military forces—combat units, service troops and command and staff; and the increased amount of artillery and other technical equipment by the larger manufacturing nations. The combat troops were still essentially infantry, cavalry and artillery. Some improvement was achieved in the combination of these three elements, but the greatest improvement was in the development of their auxiliaries. For example the wireless, and later the telephone, made signal communications and signal troops immensely important. Field entrenchments, bridge building, and other engineer works required more engineer troops. Both these services were also developed for front-line action with the combat arms. Other technical services, including administrative troops, were greatly increased in size and strength, particularly in the supply and medical functions. The control of the combat and technical services, as well as the growing complexity of armies, demanded a more elaborate system of command. Staffs became larger so that the troop commander of larger units became an executive served by specialists in many fields. For example, Count Helmuth, Carl Bernhard von Moltke (*q.v.*) superintended a number of the battles of the Germans in 1866 and 1870 without leaving his office in Berlin.

Each nation during this period of the armed camp sought the best proportions of weapons to manpower. In France and Germany, cavalry was still important; the proportions were roughly 120 sabres and 6 artillery guns to each 1,000 rifles. Understandably the Austrian and Russian armies, supported by less industrial strength, had fewer guns and more cavalry. Also their armies had a smaller requirement for technical troops. However, the true worth of the factor of industrial strength was not fully realized during this period; when war came, industrial developments compelled an increase in the proportion of technical troops. Moreover, industrial production of artillery and machine weapons brought a demand for more troops to man them, beyond the proportions determined in the prewar period.

The infantry organization became rather standardized with the battalion of 450 men as the basic unit, subdivided into four companies. The company in turn included three or four platoons, the smallest command given to an officer. This continental system was not used by the British, whose battalion included eight companies. The usual practice in Europe was to group three or four battalions into a regiment, two regiments into a brigade and two brigades into a division. The cavalry was organized into squadrons of approximately 150 horsemen subdivided into four troops, but the number of squadrons in a regiment varied from three to six and the strength from 500 to 1,000.

The battery of from four to eight guns was the basic unit of artillery. It was divided into two sections, this being the smallest command of a field artillery officer. Three batteries normally comprised a group of artillery; two or three groups became a regiment.

As mentioned above the junior officer or second lieutenant normally commanded a platoon or section of 50 to 75 men. Along with the first lieutenants and captains who commanded the companies and batteries, they furnished the basic tactical leadership of the troops. The next higher rank, that of major, was in command of a battalion of infantry or a group of artillery. Regiments were commanded by colonels. These ranks held generally for continental European armies and for the United States, but in Great Britain the units were commanded normally by officers of one rank greater than that of other armies. The organization and command of the technical and administrative services were developed on similar principles. During this period the army of the United States had no higher organization than the regiment and the British none higher than the division.

As part of the new importance given to attack, the idea of adding artillery and technical equipment to units above the size of a division became common. Though in peacetime there were no armies, maneuver groupings brought three or four divisions together as a corps, and two or more corps as an army. The term "army" came into common usage as something less than the total armed strength of a nation. Corps and armies became a useful method of adding cavalry, engineers, additional artillery and other technical troops so that the offensive could be given more impetus. The tactics of the higher units were not much developed during this period, attention being given to the relative merits of the triangle or square formation for attack. The possibility of the movement of armies under a strategic plan was however not dismissed since Moltke and later Gen. Alfred von Schlieffen developed the grand strategy of holding on the left while striking with a strong right through the Low Countries against France.

VI. WORLD WAR I

The test of battle was given to the preparations made by the European armies. The fulfillment of all preparations seemed to bring about the inevitable conclusion of armed conflict. Questions asked later were: How did the armies take the field? How did they stand the tactical test? How did they react to the new methods of warfare which appeared?

The mobilization of both the German and French armies was more rapid than anything known formerly. Within 48 hr. 2,000,000 men on each side were in motion, and within 5 days 1,000,000 Germans were actually across their frontiers and into Belgium. The gathering of the army of Germany was a prime example of efficiency. The troops moved to the attack with a spirit perhaps born of the hope that the war would be short. The German infantry was drawn up for attack in dense lines with small intervals between men. It was expected that the infantry and artillery could attain fire superiority and then move to the assault. Advancing at a walk or by short rushes up to 600 yd. from the enemy, the infantry was then to make an overwhelming assault upon the enemy at a trot. The Germans, like soldiers everywhere, tended to bunch up, making themselves a target for the effective French fire. The first great surprise of the war from the viewpoint of the soldier was the effectiveness of weapons. In no time at all the infantry began to dig in.

There were surprises for the artillery too. No longer was it possible to fire from open positions. Artillerymen had thought that a great gun duel would mark the opening of the war. They believed that artillery fire would be so devastating that the enemy artillery would be put out of action for the remainder of the battle. Subsequently artillery was to be used against the enemy infantry, thus assuring quick success. Similar ideas were held by airmen at a later date, but again the capacity of the individual to withstand heavy fire proved surprising. One of the great disappointments was suffered by the cavalry, whose doctrine was the attack; but rapid-fire guns eliminated large-scale cavalry attacks in World War I. Its chief value was in reconnaissance by small units.

Underestimation of the power given to defense by modern firearms caused tremendous changes in tactics by the fall of 1914. The conflict became a war of position on the western front by that time and on the eastern front a little later. The German idea of quick victory which dated back to Frederick had not been achieved. French valour and hastily formed reserves stopped the Germans just short of Paris. Much of what had been prepared in the years since 1870 then needed revamping, for the war of position influenced not only tactics, but organization, operations, morale and industrial support at home.

Though no organizational change occurred in the infantry, certain improvisations were put into effect to fit the system of trench warfare. Normally half the infantry of each division held the trenches while the other half remained in a rest area behind the lines. The square formation of four battalions in a regiment, two regiments in a brigade and two brigades in a division was extremely suitable for this requirement. The artillery brigade included three regiments of artillery, one of heavier calibre to support the whole division and the other two regiments of lighter calibre, each to support a brigade. Depleted divisions were sent to rest areas so that they could be brought up to strength with replacements and given a brief training period to assimilate their recruits. (For discussion of World War I tactics and armament *see* ARTILLERY; TACTICS; TANK; WORLD WAR I.)

During World War I it became obvious that warfare had become a business of all the people; every citizen was affected directly or indirectly. Governments and statesmen began to study warfare to a greater extent than at any time in history. Industry became a teammate of the military. Military leadership was confronted with the problem of properly handling masses of men, technological improvements and combat operations in vast areas. Continents became combat theatres; warfare became three-dimensional, orders were speeded by telephone and the truck made supply quicker. But strangely enough there was no shortening of the length of war or the duration of battles. Warfare became a matter of continuous fighting.

World War I also brought out the great importance of the morale of the fighting man and of the populations at home. Never before, except in the early years of the French Revolution, had so much enthusiasm for war been developed among the peoples as was common in Germany, France, Britain and the United States during World War I. The peoples' enthusiasm was the soldier's enthusiasm: their depression was likewise communicated home. Out of this necessity rose the great new emphasis on propaganda utilizing mass communication to weaken the will of the enemy. (*See* PSYCHOLOGICAL WARFARE.) Many of these innovations in weapons and the idea of total warfare were to appear in new and more devastating form in World War II, but in the interim it did not become apparent that science was changing warfare and that techniques of production and transportation would be closely interlocked with military combat. (C. L. Bo.; H. M. Ce.)

VII. BETWEEN WORLD WARS I AND II

Between World Wars I and II the technique of warfare was gripped by lethargy. Though World War I had brought the internal-combustion engine to a good state of development, had seen the arrival of military aircraft and computing devices for the control of gunfire and had seen the first beginnings in the use of radio these modern scientific techniques were little used between wars. Meanwhile new machines were created for commercial purposes and were available for adaption to military use when war did come.

The history of the period 1918–39 includes a number of localized wars such as the Russian Revolution, the Chinese civil war the Sino-Japanese War and the Spanish Civil War. The first three produced no new technical improvements but were fought mainly in the method of World War I, though later, toward the end of the 1930s, the Japanese employed tanks and aircraft in combination with their infantry. In Russia, the communists relied heavily upon military forces in their revolution. In 1917 Lenin said that the Soviets were a new state apparatus with an armed force of workers and peasants and that this force was not divorced from the people, like the old standing army, but closely tied to them. During the 1920s the Red army was utilized mainly in support of domestic policy. Its 500,000 men were trained and equipped in World War I fashion and it was not until Soviet production became strong that munitions for warfare were developed

In the few years before 1939 Lenin's concept that national defense could only be assured by the building of a powerful economy began to take shape. The army grew in number to 2,000,000 men and developed as a force more slowly than did the armies of western Europe though it did effect a few innovations in tactics and employment of troops, particularly parachutists.

Among the victorious democracies there was the belief that a beaten and disarmed Germany could not again arise in opposition. The belief that another war would never come was also widespread. Military expenditures were reduced and the armies of Great Britain and the United States, based on voluntary enlistment, were smaller than the peacetime armies of Yugoslavia, Poland and similar national states created by the peace treaty. France continued to rely on conscription but its army, too, was restricted in size by lack of funds. Youth in all these countries turned away from military service. Conscription and voluntary methods produced small-scale regular armies with difficulty.

While the western Allies were lethargic about preparation for their own defense, the defeated Germans were evading the terms of the Versailles treaty. Schemes were developed for producing forbidden munitions of war and the industrial plant to manufacture them. Thus Germany was free to develop modern machinery for war; every effort was made by German scientists and industrialists to perfect a peacetime industry whose tools could be switched quickly to mass production of munitions.

The acquisition of a trained reserve was a little more difficult. In some ways the solution was more flexible than that which Scharnhorst evolved in 1807 to raise a German army in violation of the treaty of Tilsit. At that time the treaty army of 42,000 was used to train a group, move them out into the reserve and draft another treaty force. That possibility as a loophole was excluded in the Versailles treaty since the enlistment period of the 100,000 men was fixed at 12 years. This provision of the treaty was not evaded by the Germans, who merely utilized the army to train a large officer corps for a new army. On the side athletic groups of all descriptions were established. Physical culture became a mania in Germany. This method of forming quasi-military clubs provided Germany with the organization and training of a reserve army. Though wooden models of weapons were used, a supply of armament was secretly accumulated by the Germans. When Hitler came to power he was blatant about his military strength, and in an open manner began his attempt to remake Germany into a first-class military power. Again a German leader sought a device or tactical scheme which would assure him of a quick victory. Where his forerunners had analyzed the problem out of their military experience, Hitler was free of any dependence upon tactical doctrines inherent in a military education. His major efforts were confined to the air arm and its use in conjunction with his army while at the same time increasing mobility of the army. He developed a combat team of tanks supported by aircraft.

Japanese military doctrine was similar to that of Germany. The resources of the country were utilized to develop the strength of the armed forces. Industry was turned to the munitions, and the army and its equipment were put through the school of conflict in China. Too little was known of the developments of that war as it concerned Japan and too little understood was the possibility that Japan was developing the resources with which it could strike the western democracies. The Japanese military society took on many of the same characteristics as that of Germany; the man in uniform received the adulation of the people and became a law unto himself.

In France the spirit of the people was ground down by the possibility of another war with Germany, the third in three generations. France's population had not kept pace with that of Germany and a pacifist spirit had taken hold. The great depression of the early 1930s made it imperative that every possible economy be made in military expenditures. This was the spirit of democracy which France shared in company with the United States and Great Britain. Dictatorships in Italy, Germany and the Soviet Union had no such difficulty since the productive effort of the people would be turned over to munitions in whatever proportion the leader dictated.

In the United States and Great Britain the small regular armies were trained mainly as a base for expansion in case of war. Emphasis was laid upon the training of reserve units and upon the schooling of officers and noncommissioned officers who would be called upon for leadership. Weapons were rarely new and the troops depended mainly on the use of pilot models for the development of their tactics. New weapons became obsolete so fast that no nations except the dictatorships were willing to expend huge sums for production of armament and equipment. For discussion of new weapons, tactics and training *see* ARTILLERY; TACTICS; OFFICERS, MILITARY.

Principal Characteristics of Armies.—During the interim between World Wars I and II military development did not keep pace with that of industry. The dependence of the military upon industry, however, was gradually becoming more evident. Two other factors influenced military development: the army and the navy had been joined by the air force to make war three-dimensional; and total warfare promised that armies would move faster, co-operate over greater areas, be more difficult to control and be more specialized than in the past.

The social and total aspects of war were well illustrated in the growing effectiveness of propaganda and of nerve warfare in the years immediately preceding 1939. From the time of Alexander commanders had used spies in warfare but never before had the practice become as common as was evident at the outset of World War II. The fifth column—the traitor amidst the national population—served his master well through the use of rumour, misinformation and sabotage. The objective of the fifth column was to work on the fears of the people so that in the crowded roads of Europe their movement to some place of refuge would complicate the already complex deployment of modern armies. (*See* INTELLIGENCE, MILITARY AND POLITICAL.)

By 1939 the world had had a taste of a number of small wars including one of the oddest civil wars in history. In Spain the opponents were assisted by fascists on one hand and the communists on the other. Volunteers came from all over the world either as individuals or as regular members on leave from the armed forces of Germany, Italy and the Soviet Union. On a small scale the use of airplanes in conjunction with tanks and the strafing of infantry troops was given a trial. Warfare found a larger stage when the Germans moved against Poland on Sept. 1, 1939.

VIII. WORLD WAR II

In a measure the new war began where the last one left off. Germany was again the aggressor in Europe and within three years, the war which had been confined to central Europe at the outset had spread to Russia, the near east, North Africa and the Pacific. Global warfare had come to the earth. Land campaigns were being carried out in desert, mountain, jungle and island areas. The first terrible impression was that of the blitzkrieg of the German army. The Germans had broken abruptly with the past by mechanizing their artillery and by such devices as making their well-known 88-mm. gun a triple-purpose weapon for use as a field artillery piece, antitank gun or antiaircraft gun. Attack was the watchword and lightning war was in every mind. The Germans had succeeded not only in indoctrinating their troops with the idea of the superman and of warfare for space for empire, but had also through propaganda sowed the idea of an invincible army. That legend was not dissipated until the Germans had been stopped at Stalingrad and at El Alamein. In the Pacific, the Tokyo end of the Berlin-Rome axis had demonstrated a similar capacity for lightning action and for propaganda which enhanced its capabilities and detracted from those of its enemies. The Japanese reliance was upon jungle and amphibious warfare in Indonesia and later in the southwest Pacific.

No longer were armies engaged in warfare apart from other fighting services. Land warfare became interwoven with air and amphibious operations. Land campaigns, it is true, remained a phase of warfare and the major task of armies, but they were no longer carried out separately. The army combination of infantry, artillery and tanks became a much more involved effort than in

World War I. Not only was the faster moving, heavier artillery of an army augmented by the artillery effect of aircraft, but in a number of land campaigns navy ships moved in close to shore and supported land attacks. The deadlock of World War I was not to be repeated. The German army showed that masses of mobile artillery could knock holes in an enemy and the tank-air team could move through and fan out into the enemy rear. Orthodox resistance was useless before such an effort. The initial strike of the Germans also utilized dive-bombing techniques to knock out antitank and antiaircraft guns. Radio communication was used between air and ground in the frontal areas without recourse to involved channels of command. (*See* AIR POWER.)

After the German army overran the continent it might well have conquered England had amphibious warfare and its necessary equipment been perfected by that time. In addition there was a feeling by Hitler that he could bring Great Britain to its knees and compel it to sue for peace by bombing the British population. British determination and the magnificent defense by the royal air force in the battle of Britain upset that calculation. For the remainder of the war on land the Allied endeavour was to accomplish the breakthrough of defensive lines after amphibious assaults had placed them in position for land conflict.

Size and Organization of Armies.—Armies were numbered in the millions among all the leading opponents. In general they were brought together by the use of the German system of universal liability for service. Three-dimensional warfare also required that the manpower of the nation be allocated to the air and naval forces as well as to the army. In the United States armed forces, about 11,000,000 men were in service at peak strength, of which 5,000,000 were in the army and approximately 3,000,000 in each of the other two services. However, the air force was largely supplied by the service troops of the army including port battalions, quartermaster, engineer and signal troops.

The armies of the other major nations were of like number and the Soviets the largest of all, with about 12,000,000 in the army and smaller numbers in the air force and navy. Such numbers required tremendous organization, so that army groups began to appear. In most cases an army group included two to five armies, each of the latter in turn containing from two to six corps. The Russian army groups contained in some cases as many as 2,000,000 men and 100 divisions. The U.S. division being larger, the army group under Gen. Omar Bradley included 2,500,000 men in 60-odd divisions.

During the war the expression was often heard that a nation's army reflected its social customs. That there was a great deal of truth in the statement was shown in the fact that the U.S. soldier had more vehicles and more radios than any other army in the world's history. In this same willingness to utilize mechanical advantages the U.S. army created an organization with an overwhelming proportion of artillery. Only the Russians had anything comparable in numbers of guns. Toward the end of the war the Germans complained, rather strangely, that they were being defeated by superior machine power and inferior military manpower.

The organization of the units underwent no great changes from the prewar period. The divisions throughout the world were generally from 11,000 to 15,000 men, except for airborne units, which varied between 6,000 and 10,000. The idea of a division was expanded to include what is known in military terminology as the service support or ancillary troops. The division had to be supplemented by several thousand engineer, signal, medical and quartermaster troops who were attached to serve with it. The army corps became far more than a combination of two or more augmented divisions since it was used administratively to carry tremendous numbers of additional troops. The larger calibres of artillery in great numbers were assigned to a corps for special operations. There were separate regiments of infantry, special service troops, psychological warfare units and troops to exercise dozens of other specialties of modern warfare. This supplementation of troops was even greater in armies and in army groups. Here were included uniformed women serving in clerical and signal work, overseas as well as at home. The preparation of these vast organizations required elaborate systems of training and a great amount of improvisations in tactics in their employment. For tactics, training and armament of World War II *see* TACTICS; ARTILLERY; TANK.

Command.—The units commanded by the various officer ranks remained unchanged throughout the war. The significant change in the chain and method of command and staff procedure was in the creation of joint and combined commands. In most cases the armed forces, including army, navy and air force of one nation, were placed under a single commander in a theatre of operations. Two alternative methods were used. One method was to organize a joint staff, including proportionate numbers of army, navy and air officers, while in the other the commander utilized the staff of his own service, augmenting it with a number of officers from the other two services. Similar procedures were carried out in combined commands where two or more nations were involved. Gen. Dwight Eisenhower in his supreme headquarters integrated British and U.S. officers on an equal basis throughout his staff. (*See* STAFF, MILITARY.)

Conclusion.—During the last year of the war the campaigns on land followed the pattern of the early German blitzkrieg. There was a breakthrough, wide sweeps by tanks and the speed and complexity of mobile warfare. In the Pacific battle areas amphibious armies were utilizing new techniques to get ashore rapidly. Once on land their tactics were similar to those in combat in Europe. There was no tactical deadlock as in World War I, yet the facilities and the strength of the defense had improved tremendously.

It was the co-ordination of the troops, their fire and movement, the shock effect of tanks upon an exhausted enemy and the leadership of able men which made possible the success of offensive tactics against the greatly strengthened defense during the last year of war. (*See* WORLD WAR II.) (C. L. Bo.)

IX. ARMIES AFTER WORLD WAR II

By 1950 there had developed a remarkable readiness on the part of anti-communist nations to unite in determined measures not alone for their own defense but for the maintenance of peace and order the world over. The past had witnessed countless alliances for a limited season of defense or offense; this mid-century development, following closely on World War II, was founded on a broader base and upon a more efficient pattern. That is, while each participating nation retained its complete sovereignty and its right of withdrawal from the alliance, each also, in two notable cases, without question accepted the principle of a supreme command to whose authority each sovereign state committed the control of its forces and its resources.

The cases referred to are the United Nations (UN) action in Korea, beginning in 1950, and the organization of the 15-state North Atlantic Treaty organization (NATO), made up in 1950 of Belgium, Canada, Denmark, France, Iceland, Italy, Luxembourg, the Netherlands, Norway, Portugal, the United Kingdom and the United States, with Greece, Turkey and the German Federal Republic entering later. The NATO establishment was specifically for the defense of the west, through a co-operative upbuilding of military and economic resources of member nations. All were politically equal; Iceland, with no military forces but with a geographical position of importance in sea or air activities, had a vote as large as that of the United States, and political decisions at the NATO council were made on the basis of equal voice. But the supreme military command was genuinely supreme, in that whatever resources were tendered by the member states were administered under direction of the high command, whether the naval command in the Atlantic or the military command in western Europe.

It was inevitable that so long as the Soviet threat was thought to be severe the assignment of forces to the NATO supreme command was generous; later, when the threat was thought to have lessened (both because Moscow began giving assurances of benign intentions and because most of the western nations were conspicuously stronger than in 1950) the actual assignment of forces was in many cases reduced. However, the principle of co-operation was never altered.

The co-operation in Korea sprang from the same general

motive; that is, a willingness to unite for the preservation or, in this case, the restoration of peace. Unified action came about not after months of consideration, as did NATO, but with great suddenness. Before the North Korean forces could push far beyond the border, the Republic of Korea (South Korea) had called for help, and the United States had urged intervention by the UN to halt the invasion. Because the United States was clearly best fitted to supply major reinforcements for the South Koreans, the UN forces were assigned to the United States far east commander. It is important to note, however, that the command so exercised was that of the UN, and that the several national contributions were by UN members who were at all times fully sovereign and at liberty to withdraw, yet submitted voluntarily to the supreme command.

This whole development must have been influenced by the harmony of British and U.S. co-operation in World War II, when separate sovereignty was never in question, yet the supreme command was also a reality, first in northwest Africa, then in the Mediterranean and finally in the campaign across France in 1945. The co-operation which had proved practical even under the strains of World War II proved equally applicable to the "cold war" in the west and to the limited war on the Korean peninsula.

This development of far-reaching military alliances and genuinely supranational military forces, however, formed only part, a dependent part, of the new picture of warfare. For these political developments, new as they were in scope and conception, reflected merely the attempts of the western nations to deal with a new way of life.

The dropping of the atomic bomb over Hiroshima on Aug. 6, 1945, followed by another over Nagasaki, heralded more than the surrender of Japan and the end of World War II. It marked also the dawn of a new era in warfare, in which nuclear fission (and later nuclear fusion) would prove employable in a variety of ways. That for years thereafter nuclear weapons were used only in proving-ground tests, rather than in actual warfare, was the world's good fortune and easily explained. Conflicts of the decade immediately ensuing, such as that in Korea, required no such immense destructive powers as all early atomic weapons possessed; only as nuclear technology improved was it found that the essential "critical mass" could be reduced far below the 1945 estimate and the minimum destructive power accordingly be so decreased as to permit smaller weapons and a degree of flexibility in battlefield operations.

Immediately after World War II military technologists in co-operation with nuclear scientists began to study with great earnestness the problem of reducing both the weight and the bulk of the Hiroshima-type atomic bomb. Progress was soon apparent both in the production of a fission bomb so much smaller than the 1945 prototype that it was readily portable in a moderate-sized plane instead of a heavy bomber and, by 1952, in the production of a heavy artillery shell. By the mid-1950s there resulted a considerable series of atomic weapons, all being supplied to specially trained gun, mortar and rocket battalions, including some allotted to the North Atlantic Treaty organization's European headquarters.

The rapid development of nuclear weapons (and a little later the much more powerful thermonuclear weapons as well) had a revolutionary effect in several areas of military planning. Inevitably new weapons call for new tactics and these for new organizations to exploit both weapons and tactics. They also call for new counterweapons. The nuclear weapon obviously was a very great addition to firepower, but its true importance was determined also by the means of propelling it, and the means of guiding it precisely toward a target. The guns and heavy mortars of the army had more accuracy than range; the propeller-driven plane which had launched the first bomb at Hiroshima possessed great range but inadequate speed; but the swiftly developed successors to these launching devices, both from the surface and from the air, added greatly to the nuclear threat, combining speed, range, altitude and firepower, and inevitably added to the problem of devising defenses against such a threat.

Thus, when for many combat purposes the propeller plane was succeeded by the jet-driven plane, and when at about the same time atomic bombs were being both compressed into smaller packages and produced at a tolerable cost, it became apparent that this destructive power could be transported by an enemy at a much faster pace than in 1945 and in greater numbers and hence with wider dispersion. When, in succession to the jet, the rocket, revived by the Germans during World War II in the form of the V-2, was more fully developed in succeeding years, it emerged as a potent partner for an atomic warhead. For the high-thrust rocket, with electronic guidance, provided the atomic warhead with hitherto undreamed-of speed, range and trajectory in space, and hence with a high degree of invulnerability to most then-existent means of intercepting it or even of detecting it in time for useful action.

Early discussions of what could be done, theoretically, by the intercontinental ballistic missile, once perfected, fairly shook the reason of laymen over much of the civilized world. This mechanical monster was described so vividly that many were persuaded that it was an early prospect rather than a mathematical possibility which could come into being only several years in the future. A missile traveling at 18,000 m.p.h. or more, most of the way high above the earth's atmosphere and thus defying detection by radar, and plunging with its thermonuclear warhead to the target 5,000 mi. from the launching point, was patently something defying all defensive measures of the day. It was necessary, therefore, for planners in the mid-20th century first to point out that moderate precision would be necessary for an effective assault weapon, and that technologists had not yet achieved precision with a ballistic weapon of much shorter range. Next it was necessary to give assurance that, costly and complex as it must prove, interception even of such a monster was theoretically possible. Of greater comfort to some was the viewpoint, offered by many authorities, that, with more than one great nation experimenting in nuclear weapons on a grand scale, a standoff was increasingly possible; that is, the certainty that nuclear aggression would be instantly followed by retaliation, and that even the victor would be terribly shattered in such a duel, could offer hope that aggression would be automatically deterred.

The human longing to accept this viewpoint as assurance rather than hope did not, however, blind chiefs of state to the need for thermonuclear armaments for both offensive and defensive action. Rather, it made the need seem imperative. As the sixth decade of the 20th century advanced, accordingly, the U.S. and the U.S.S.R. were engaged in building up ever greater strength in nuclear weapons and in devising means of delivering them against a foe by long-range missiles, medium-range missiles launched from advanced land bases, surface and submarine vessels and high-altitude aircraft. In both countries, moreover, there was experimentation with defenses against such weapons. Of the U.S. efforts it is possible to speak with greater exactness, for the publicity permitted in the United States, in contrast with Soviet silence, included description not only of the interception equipment (planes at readiness and strategically situated batteries of guided missiles) but also of the early-warning detection systems. These reached as far as the Arctic circle and were linked to a mechanically operated network of computers and directors to provide fair promise of detection of an enemy attack and of almost instantaneous direction of interceptors to their fast-moving target. This represented a knitting together of land, sea and air forces to a degree never before attained. Although it came about gradually in the United States, this unity of forces had in fact been rendered inescapable.

Speed, all but annihilating historic concepts of distance, transformed early plans for the division of responsibility among the armed services, and there was an unprecedented mutual dependence among them, however reluctantly admitted.

Air power, which during World War II had grown vastly in importance by reason of the immense advance in the airplane's speed, power, range, versatility and reliability, continued to progress in most nations. The new army concept was of infantry divisions barely distinguishable from air-borne divisions, in that they would be transported largely by wing and rotor rather than by wheels.

In the meantime, military commands of all countries were compelled to work desperately to obtain popular support and sufficient funds to maintain armies at current strength. Atomic weapons plus supersonic propulsion systems formed a combination which to many seemed to press the conventional ground forces far toward obsolescence and hence to remove justification for all large armies. However, it was argued that, while the fear of an atomic war undoubtedly had deterred aggression which might bring atomic-weapon retaliation, it had failed to prevent local aggression and "fringe" fighting which was just short of provoking such retaliation; in fact, local communist aggression had demonstrably proceeded in Europe and Asia, and had led to communist absorption of large areas and populations. The reasoning, therefore, was that while powers of massive retaliation should be maintained and even increased, the tendency to whittle away the conventional forces (those not armed with atomic weapons) should be halted, for on these forces would depend the outcome of the only predictable wars—namely, such further local wars as had already thrived in the shadow of the atomic bomb threat.

Upon the ground forces, therefore, fell the responsibility for maintaining armies that would not only be in readiness for the quick suppression of local wars in which atomic weapons would not be used but would also be capable of offense and defense alike in a major war employing atomic weapons. With necessary concern over costs, the effort was to serve both purposes so far as possible with the same means. This led to sharp concentration on new equipment and tactics, seeking maximum mobility, communications and firepower. Only with these possessions could the new tactics be devised. These tactics contemplated a wide but methodical dispersion of units and installations to avoid providing profitable targets for the enemy, and a rapid concentration of force needed for air-borne assault on a profitable enemy target, to be followed by rapid withdrawal and another dispersal. The new tactics called for great division of responsibility among lesser commanders, and this in turn demanded both a high degree of training and an unprecedented network of radio communications. Courage and devotion remained essential as always; yet, as always, these were not nearly all that was required; advanced technologies became far more important than ever before; aggressive and resourceful leadership, too, had to be asserted at every level of command. Organization itself, accordingly, had to be radically revised.
